EXPERIMENT STATION RECORD

VOL. 69

JULY 1933

No. 1

EDITORIAL

GENERAL INDEXES TO EXPERIMENT STATION RECORD

The recent publication of the fifth general index to *Experiment Station Record* makes available in convenient form subject-matter references to all material printed in these columns before July 1929. In accordance with the policy of recent years, this index includes 10 volumes of the *Record*, covering volumes 51-60 and the 5-year period 1924-29. Since the current issue of the *Record* commences volume 69, no further general index is scheduled for issue for some time, although its preparation by consolidation of the separate volume indexes thus far completed has been begun, and in this form it is already available for consultation in Washington.

The general index for volumes 51-60 follows closely along the lines of its predecessors, as it is realized that continuity of policy and treatment is wellnigh indispensable. Some economies have been effected but without serious loss, it is hoped, of practical efficiency. Entries derived from experiment station and Department publications are again specifically indicated.

The total number of pages in the new index is 682 as compared with 709 with the index immediately preceding. The subject entries aggregate well over 50,000, and to many of these, of course, a number of references are made. These figures are only approximate, but they indicate how extensive are the ramifications of agricultural science under present conditions, as well as the virtual impossibility of keeping abreast of its developments without the aid of abstract journals and similar bibliographical aids.

Largely because of the high cost of publication of a general index, the edition is much smaller than that for the monthly issues of the *Record*, and it is therefore impracticable to attempt a distribution to the regular mailing list. The needs of libraries are being met, however, and it is thought that the supply will permit of a reasonably complete institutional distribution as well. Individuals and others not eligible for inclusion in the free distribution should find no difficulty in purchasing it through the Superintendent of

Documents, Government Printing Office, Washington, D.C. The price set by that official is 60 c. per copy.

Similar conditions have prevailed on previous general indexes, but some variations exist as to the reserve stock of those indexes which are still available. The edition of the first general index, covering volumes 1-12, was completely exhausted some time ago even as to the sales quota. Fortunately the original plates have been preserved, and steps have recently been taken to reprint a small number of copies in the immediate future. When available this reprint should enable libraries to complete their files in this respect without cost, as well as to provide by purchase for the needs of the many individuals who have had difficulty in obtaining this index in the past.

Of the subsequent general indexes, that for volumes 13-25 may still be purchased from the Superintendent of Documents at \$1 per copy. The indexes for volumes 26-40 and 41-50 are sold at 75 c. and \$1.25 per copy, respectively, but they are also still available for institutional use in the free distribution. Within the limits of the supply, the needs of teaching and research departments and similar groups will be met on direct application to the Office of Experiment Stations, U.S. Department of Agriculture.

THE RECORD NOW A MONTHLY

Communications still being received in considerable volume as to alleged nonreceipt of certain issues of the *Record* indicate continued misunderstanding as to the frequency of publication. As explained at the time of the change (E.S.R., 67, p. 193), beginning in September 1932 all so-called "abstract numbers" were eliminated. Six monthly issues with index, therefore, complete a volume, instead of nine numbers and index as formerly.

The enlargement of the individual numbers from exactly 100 to an average of 150 pages each has proved economical and on the whole advantageous. However, since the numbers no longer contain precisely 100 pages, locating citations to previous work is, as was foreseen, somewhat less convenient. Recently this difficulty has been lessened to some extent by printing on the binding edge of each number not only the title and date but the pages which the number includes. This should facilitate reference to the several issues pending binding, following which stage the matter becomes of less importance.

RECENT WORK IN AGRICULTURAL SCIENCE

AGRICULTURAL AND BIOLOGICAL CHEMISTRY

[Chemical investigations of the California Station] (*California Sta. Rpt. 1932*, pp. 28, 29).—Data are included on the prevention of olive spoilage and on decrease of oil content on pickling, on the intensification of corrosion in grape juice by sulfurous acid, and on the resistance to corrosion by orange juice of stainless steels.

[Chemical investigations of the Iowa Station], C. H. WERKMAN ET AL. (*Iowa Sta. Rpt. 1932*, pp. 31, 32, 48, 49).—Notes are given on the work on fermentation products of xylan; fermentation products of levulose, produced by *Aerobacillus*; adaptation and development of the method of partition between solvents for the determination of fermentation products; nature of the floridin activation of cholesterol; and the identification of the water-soluble and the acid hydrolyzable carbohydrate constituents (hemicelluloses) of the cornstalk.

[Chemical studies of wheat flour and oil] (*Indiana Sta. Rpt. 1932*, p. 57).—Data are reported on the keeping quality of soft wheat flour as measured by the bacterial content and on the iodine number of wheat oil as a test of rancidity.

Report of the assistant chemist, J. O. CARRERO (*Puerto Rico Sta. Rpt. 1932*, pp. 8–11).—The report of the previous year (*E.S.R.*, 67, p. 500) is continued with notes on the chemical composition of sugarcane variety P.O.J. 2878 and on the chemical behavior of its juice in processing.

Factors affecting the jellation of fruit juices and pectin solutions, P. B. MYERS and G. L. BAKER (*Delaware Sta. Bul. 179 (1932)*, pp. 28, 29).—This work included the measurement of a number of the more important physicochemical properties of pectin.

The muslin tube fruit juice filter, R. B. HICKOK and R. E. MARSHALL (*Michigan Sta. Quart. Bul.*, 15 (1933), No. 3, pp. 191–197, figs. 3).—The device described consists essentially of a muslin tube about 3 in. in diameter, about 3 ft. in length, closed at one end by folding and tying, and attached at the other end to a rubber hose bringing the cider from a tank placed at such a level as to give a net head not exceeding 15 ft. It was found advantageous to support the filter tube on copper wire screening in a wooden trough inclined slightly from the horizontal. Details of construction are shown in a drawing and a photographic plate. The device is designed for the filtration of cider from which the suspended matter has been precipitated by enzyme action, and to which a suitable filter aid has been added. Cider treated as described could be filtered at the rate of about 3.3 gal. per minute during the flow of the first 5 gal. at a net head of 14 ft., the rate decreasing gradually with increase in the thickness of the filter cake. The possibility of applying the method, with suitable modification, to such other home products as vinegar and various fruit juices is pointed out.

Oil content of nine varieties of soybean and the characteristics of the extracted oils, G. S. JAMIESON, W. F. BAUGHMAN, and R. S. MCKINNEY (*Jour. Agr. Res. [U.S.]*, 46 (1933), No. 1, pp. 57, 58).—The authors of this contribution from the U.S.D.A. Bureau of Chemistry and Soils determined the oil content of seed from 9 varieties of soybeans grown in the United States, finding the quantity to range from 15.6 to 19.3 percent. The iodine number of the extracted oils determined by Hanns method ranged from 127.8 to 141.4; saturated acids ranged from 11.7 to 12.6 percent and unsaturated acids from 80.1 to 81 percent.

Differences in the amino acid content of the chief protein (glycinin) from seeds of several varieties of soybean, F. A. CSONKA and D. B. JONES (*Jour. Agr. Res. [U.S.]*, 46 (1933), No. 1, pp. 51-55).—The authors of this contribution from the U.S.D.A. Bureau of Chemistry and Soils determined colorimetrically the cystine, tryptophane, and tyrosine contents of glycinin preparations extracted from 10 varieties of soybeans. The glycinin preparations agreed fairly closely in composition but showed some significant differences. The tryptophane values ranged from 1.89 percent in the protein of the Mammoth Yellow variety to 2.84 percent in that of the Illini variety. The cystine values ranged from 0.74 percent in the protein of the Illini variety to 1.46 percent in that of the Chiquita variety. These variations in composition are attributed to variations in the proportionate quantities of the various globulins contained in the glycinin preparations.

It is noted that the Illini variety, because of its higher tryptophane content, should be of value as a supplement to feeds low in tryptophane, such as corn and oats; and that feeds deficient in cystine, such as cowpeas, lentils, and peas, should be improved more by supplementing with Chiquita and Manchu soybeans than by additions of the Peking and Illini varieties, which are comparatively low in cystine.

The mechanism of sulfur lability in cysteine and its derivatives.—I. Some thio ethers readily split by alkali. II. The addition of mercaptan to benzoylaminoacinnamic acid derivatives, B. H. NICOLET (*Jour. Amer. Chem. Soc.*, 53 (1931), No. 8, pp. 3066-3072; *Jour. Biol. Chem.*, 95 (1932), No. 2, pp. 389-392).—The author of this contribution from the U.S.D.A. Bureau of Dairy Industry describes in the first of the two papers here noted certain β -ketonic sulfides which are very readily split by alkali to give mercaptans and α , β -unsaturated ketones. A structural analogy between these compounds and cysteine or cystine is pointed out, and some reasons are given for considering as analogous the action of alkali on the two classes of compounds. "From these considerations, a mechanism for the alkaline decomposition of cysteine has been developed, and reasons have been indicated for the anticipation of greatly increased reactivity in certain specified types of cysteine and cystine derivatives."

The second paper records the preparation of ethyl α -benzoylamino- β -tolyl-mercapto- β -phenylpropionate from 2-phenyl-4-benzal-5-oxazolone and p-tolylmercaptan in benzene solution by treatment with sodium ethylate solution; of the corresponding methyl and butyl esters; and, from the last-named ester, of a compound "presumed to be the sulfone of the butyl ester", obtained by oxidation with acidified permanganate in chloroform solution. Treatment of the above-named azlactone in benzene solution with sodium ethylate in absolute alcohol solution under specified conditions readily produced ethyl α -benzoylaminoacinnamate in good yield.

The tyrosine content of cocoons of various species, A. K. SILBERMAN and H. B. LEWIS (*Jour. Biol. Chem.*, 95 (1932), No. 2, pp. 491-494).—The authors of

this contribution from the University of Michigan found a high content of tyrosine in many of the species studied, these including the American tent caterpillar (*Malacosoma americana*) and a number of other species not concerned in the production of commercial silk. However, "a high tyrosine content is not an invariable characteristic of the proteins of the cocoon, since in a number of species, values for tyrosine comparable to those of more common proteins were obtained." The cocoons of Glover's silk moth (*Samia gloveri*) yielded 12.36 percent of tyrosine on the basis of the moisture- and ash-free protein, as against 9.75 percent from the silk proteins of *Bombyx mori*.

Studies of the peptides of trivalent amino acids.—II, Titration constants of tyrosyl-tyrosine and of glycyl-tyrosine, J. P. GREENSTEIN (*Jour. Biol. Chem.*, 95 (1932), No. 2, pp. 465-475, fig. 1).—Continuing this series of contributions (E.S.R., 67, p. 196), the author here presents his determinations of the apparent dissociation constants of tyrosyl-tyrosine and of glycyl-tyrosine at 25° C.

He further shows "that the assignment of the pG' value of about 10 to the feebly acid hydroxyphenyl group in tyrosine is consistent with the behavior of the peptides of this acid. The dissociation of the hydroxyphenyl group depends upon its relative position in the molecule with reference to other free groups, being increased slightly by proximity to an amino and decreased slightly by the nearness of a carboxyl group. The free amino and carboxyl groups in the tyrosine peptides are weaker as compared with similar groups in the amino acid. The isoelectric points of the complexes are likewise more acid than that of tyrosine itself."

Some factors involved in the biological production of acetone and butyl alcohol, L. WEINSTEIN and L. F. RETTGER (*Jour. Bact.*, 25 (1933), No. 2, pp. 201-238, fig. 1).—An alcohol-soluble protein or closely allied or associated substance appeared necessary for normal acetone and butyl alcohol production from carbohydrates in a semisynthetic medium. H-ion concentration, method of anaerobiosis, oils, concentration of peptone, and type of medium used had no apparent influence on the production of butyl alcohol from carbohydrate in a semisynthetic medium to which a prolamine in some form had not been added. In the presence of prolamine, or prolamine-allied substance, acetone and butyl alcohol were formed from xylose, arabinose, and glucose in the ratio 1:2. In the absence of the alcohol-soluble protein, normal quantities of acetone were produced, but little or no butyl alcohol was formed. The acid hydrolysis of the various raw materials used gave good yields of reducing sugars; and a second and more vigorous hydrolysis increased the total sugar yield materially. Fermentation of the acid hydrolyzates in the absence of a prolamine yielded appreciable quantities only of acetone. The addition of yellow corn containing the alcohol-soluble protein, zein, resulted in the production of relatively large quantities both of acetone and of butyl alcohol.

"Prolamine probably does not act as a catalyst in the reaction, or at least solely as a catalyst. Butyl alcohol is not derived from the prolamine. Alcohol-soluble proteins in all probability influence favorably the production of butyl alcohol from carbohydrate material in a semisynthetic medium through a combination of their physical action and their direct influence on the metabolism of *Clostridium acetobutylicum*."

On the preparation of hemolytic and precipitating sera, H. J. STAFSETH (*Science*, 76 (1932), No. 1976, p. 444; *abs. in Michigan Sta. Quart. Bul.*, 15 (1933), No. 3, p. 208).—Blood serum was found an entirely satisfactory substitute for red corpuscles when used as an antigen in the production of hemolytic sera. The practical value of this observation—namely, the superiority

of sterile serum to whole blood or washed red corpuscles in keeping quality—is noted. Rabbits immunized with red corpuscles also yielded good precipitating sera. It was shown that extracts of washed liver or spleen tissue are not satisfactory for the production of precipitins and hemolysins, however.

Lethal effect of alternating current on yeast cells, R. L. TRACY, JR. (*Jour. Bact.*, 24 (1932), No. 6, pp. 423-438, figs. 5; also *California Sta., Calif. Com. Relat. Elect. Agr., Prog. Rpt. 19* (1932), pp. 423-438, figs. 5).—Lethal temperatures for 1, 5, and 15 minutes were first quantitatively determined for a strain of *Saccharomyces ellipsoideus* in grape juice; and it was then shown that “by passage of alternating current through yeast cell suspensions in grape juice at nonlethal temperatures, 42° C., pronounced killing effects were obtained, indicating that alternating current of 60 cycles exerted a lethal action independent of temperatures.” The lethal effect of the current varied with the current density and with the quantity of electricity applied. Electrically treated grape juices were not toxic nor lacking in nutrient values for yeast after exposures of 30 minutes. The gases evolved from the electrolysis were not toxic to yeast cells.

“It is possible that the killing effect exerted by alternating current on yeast cells is caused by the formation of temporary toxic substances like free chlorine, and that these are immediately reduced upon cessation of the current, and thus disappear. Such an action as this would directly follow the electrical conditions determined as necessary for killing the yeast cells.”

Application of statistics to problems in bacteriology.—I, A means of determining bacterial population by the dilution method, H. O. HALVORSON and N. R. ZIEGLER (*Jour. Bact.*, 25 (1933), No. 2, pp. 101-121).—The development of equations for use in the interpretation of dilution data is shown, and with them are given tables of exponential functions and reciprocals and a probability table.

Isolation of “oryzanin” (antineuritic vitamin) from rice-polishings, I, II, S. OHDAKE (*Bul. Agr. Chem. Soc. Japan*, 8 (1932), Nos. 1-3, pp. 11-46, pls. 2, figs. 43; 7-9, pp. 111-119, pls. 2, figs. 5).—The first of these two papers is a more detailed report of an investigation noted from a preliminary report (E.S.R., 66, p. 691). Further investigation of the chemical nature of the crystals isolated from active oryzanin showed the presence of sulfur, and consequently the formula suggested for the crystalline vitamin hydrochloride has been changed to $C_{12}H_{16}N_2SO_4 \cdot HCl$.

The second paper reports the preparation of the hydrochloride, picrolonate, picrate, chloraurate, and chloroplatinate of oryzanin, with their physical and chemical reactions and percentage composition. The free base was also obtained as a hygroscopic amorphous substance soluble in water, alcohol, methyl alcohol, and acetone, but insoluble in ether and benzene. The analytical results agreed in all cases with the formula $C_{12}H_{16}N_2SO_4$ for the base substance as given in the report noted above.

The purified hydrochloride crystallized in colorless long plates, melting with decomposition at from 249° to 250° C., uncorrected. In this form it cured and protected both pigeons and rats from polyneuritis in daily doses of from 0.005 to 0.01 mg.

Microphotographs are given of the crystals of the various vitamin salts, together with the ultraviolet absorption spectrum of the hydrochloride.

Chemical investigations on vitamin B, [trans. title], H. MISAWA (*Jour. Biochem.*, 15 (1932), No. 3, pp. 439-471, figs. 24).—Following the method of Jansen and Donath (E.S.R., 57, p. 489), with particular attention to the adjustment of the H-ion concentration of the medium at the adsorption stage

as recommended by Salmon, Guerrant, and Hays (E.S.R., 61, p. 91), the author obtained a crude crystalline preparation of vitamin B (B_1) which protected pigeons in doses of 0.007 mg daily and had a rat unit value of 0.02 mg. The strength of various reactions such as the Pauly, Jendrassik, and Folin and Denis tests was not decreased in the successive fractions. Other tests indicated that pure vitamin B_1 contains no phosphorus and is optically inactive. A concentrated solution of the vitamin in absolute alcohol was found to give two absorption bands at from 300 to 310 $m\mu$ and from 280 to 250 $m\mu$.

A relatively simple method is described for preparing from rice germs a concentrate for therapeutic use. The adsorption product on acid clay is brought to a total acidity of 5 percent, treated with a solution of 50 percent phosphotungstic acid in 5 percent sulfuric acid, and allowed to stand overnight in the refrigerator. The precipitate is then filtered with suction, washed with 5 percent sulfuric acid, transferred to a mortar, ground with a small volume of water and a slight excess of solid barium hydroxide, and filtered again with suction into 15 cc of M H_2SO_4 . The residue is treated twice in the same manner, and the combined filtrates, after neutralization with saturated barium hydroxide and complete removal of the excess barium sulfate, are concentrated at a low temperature (about 50° C.) in a vacuum and the resulting precipitate dried in a sulfuric acid desiccator. The yield from 2 kg of rice germs is from 3.06 to 3.47 g of a strongly hygroscopic yellowish brown resinous material which forms in 2 percent solution in water a clear yellowish brown neutral solution. From the pigeon dosage of 0.5 mg per day the dosage for human therapy is calculated as 0.15 g. When dissolved in 1 to 2 percent salt solution the material can be injected subcutaneously, with no discomfort, and in this form is called Embrin.

The reducing capacity of plant food materials and its relation to vitamin C, I-V [trans. title] (*Ztschr. Untersuch. Lebensmit.*, 63 (1932), Nos. 1, pp. 1-30; 3, pp. 241-283, fig. 1).—Five papers are presented.

I. *The reducing substance of lemon juice* [trans. title], J. Tillmans, P. and W. Hirsch (pp. 1-21).—Observations that vitamin C-containing plant substances have a reducing capacity toward 2,6-dichlorophenolindophenol suggested that the reducing substance responsible for this reaction is related to or identical with vitamin C. This paper reports attempts to isolate the reducing substance and establish its identity with vitamin C by comparing the reducing capacity of the various fractions with their antiscorbutic activity. The method followed involved decitration of large quantities of lemon juice by decomposition with sulfuric acid and neutralization with calcium carbonate and successive treatment with acetone, barium hydroxide, lead acetate, acetic acid and ether, and acetone. The reducing capacity of the various fractions toward 2,6-dichlorophenolindophenol was determined by a titration with the indicator as oxidant in acetic acid-sodium acetate buffer solution at pH 7, at which pH value the indophenol compound was deep blue in the oxidized, colorless in the reduced, state. The end point was a blue color, permanent for 1 minute.

Although attempts to obtain the concentrate in crystalline form were unsuccessful, the final concentrate corresponded in chemical properties to the known properties of concentrates of vitamin C and protected guinea pigs against scurvy at a dosage with a reducing value corresponding to that of 1 cc of fresh lemon juice.

The authors conclude that the reducing substance is the carrier of the antiscorbutic properties of lemon juice. A note added in proof calls attention to the similarity in properties between the reducing substances and the hexuronic acid of Szent-Györgyi.

II. *The question as to whether the reducing material of lemon juice acts as a stabilizer for the real vitamin* [trans. title], J. Tillmans, P. Hirsch, and F. Siebert (pp. 21-30).—Attention is called to the hypothesis advanced by Zilva (E.S.R., 60, p. 595) that the reducing substance in lemon juice acts as a stabilizer for vitamin C. An investigation of this possibility is reported, with the conclusion that the effect of vitamin C is due to the reducing substance and its primary oxidation product and that the first stage of the oxidation is probably reversible.

III. *The content of various fruits and vegetables in the reducing substance* [trans. title], J. Tillmans, P. Hirsch, and J. Jackisch (pp. 241-267).—This paper reports a comparison of the reducing capacity of various plant materials as determined by titration with 2,6-dichlorophenolindophenol with the vitamin C content of the same materials as reported by Scheunert (E.S.R., 62, p. 395) and Von Hahn (E.S.R., 68, p. 860).

Four methods of extraction were tested. The finely divided material was allowed to stand in an atmosphere of nitrogen for 24 hours in water or from 2 to 3 percent of sulfuric acid or heated in the same solvents for 10 minutes. Of the four methods, the extraction obtained by heating with sulfuric acid in general gave the highest values. The technic for the extraction and subsequent titration is described in detail. In the tabulated data figures are given for the so-called titration value or the number of cubic centimeters of the blue 0.001 N solution decolorized by the hot sulfuric acid extract from 10 g of the material and for the comparison value obtained by dividing the titration value by the corresponding guinea pig units, as reported by Von Hahn.

In general the titration values showed satisfactory agreement with the antiscorbutic activity. Discrepancies in the values for preserves were attributed to dissolved metallic salts. The method proved unsatisfactory for green leafy vegetables on account of the presence of other reducing substances.

Iodine titration values were also obtained but proved less specific.

IV. *The reversibility of the oxidation of the reducing substance in lemon juice* [trans. title], J. Tillmans, P. Hirsch, and H. Dick (pp. 267-275).—A study of the behavior of the reducing material in lemon juice toward various oxidizing agents is reported, with the conclusion that the oxidation is reversible with 2,6-dichlorophenolindophenol, iodine, and hydrogen peroxide, although on long standing the oxidized material undergoes irreversible changes. With chlorine the oxidation may be reversible or irreversible and with atmospheric oxygen is always irreversible. A note added in proof calls attention to the agreement between these findings and those reported by Szent-Györgyi for his hexuronic acid.

V. *The antiscorbutic action of various extracts of cucumber* [trans. title], J. Tillmans, P. Hirsch, and J. Jackisch (pp. 276-283).—To study further the difference in reducing values of extracts of plant materials obtained as noted in the third paper, the antiscorbutic properties of cold water and hot sulfuric acid extracts of cucumber were tested on guinea pigs. The antiscorbutic properties of the extracts ran parallel to their reducing values. The low reducing value obtained with the water extract is attributed to the presence of some of the reducing material in a reversible oxidized form as shown by titration with hydrogen sulfide.

Vitamin C [trans. title], J. TILLMANS and P. HIRSCH (*Biochem. Ztschr.*, 250 (1932), No. 1-6, pp. 312-320).—This refutation of the theory of Rygh and Rygh concerning the nature of vitamin C is essentially a summary of the series of studies noted above.

Narcotine and vitamin C [trans. title] O. DALMER and T. MOLL (*Hoppe-Seyler's Ztschr. Physiol. Chem.*, 209 (1932), No. 4-6, pp. 211-230, fig. 1).—Data are reported refuting in every detail the conclusion of Rygh et al. concerning the relationship of narcotine to vitamin C (E.S.R., 67, p. 648).

A footnote added in proof states that a preparation of hexuronic acid has been tested for antiscorbutic properties with positive results.

Critical review of recent work on vitamin C [trans. title], E. OTT and K. PACKENDORFF (*Hoppe-Seyler's Ztschr. Physiol. Chem.*, 210 (1932), No. 1-2, pp. 94-96).—In view of the disputed question as to the relationship of vitamin C to narcotine, the authors attempted to repeat the work of Rygh (E.S.R., 67, p. 648), making use also of the Tillmans reducing test for determining antiscorbutic activity as noted on page 8.

Attempts to isolate narcotine from lemon juice were occasionally but not always successful. An unknown substance was consistently obtained which crystallized in needles melting at 121° C. It was neutral in reaction and contained a methoxy group but no nitrogen. The water-soluble fraction of the ether extract contained a reducing substance which gave the Tillmans test for antiscorbutic activity, and also showed chemical properties identical with those of hexuronic acid obtained from glucose and mannose.

The nature of vitamin C [trans. title], J. TILLMANS (*Ztschr. Untersuch. Lebensm.*, 64 (1932), No. 1-2, pp. 11-20).—The author reviews in considerable detail recent research on the chemical nature of vitamin C, including the work of Bezssonoff, Zilva, Rygh, and Szent-Györgyi, and his own studies. In his opinion the hexuronic acid of Szent-Györgyi is identical with the reducing substance which he has postulated as the cause of antiscorbutic activity in plant materials. The properties of the reducing substance which are in close agreement with hexuronic acid are as follows: It is an organic carboxylic acid, contains no nitrogen, and is not a tannin or polyphenol. It is closely related to carbohydrates, for the Molisch reaction is positive. It has typical oxidizing reducing properties, the reaction being reversible with indophenol, hydrogen peroxide, and iodine, and irreversible with oxygen. It appears to be an oxygen catalyzer and as such plays a role in the oxidation processes of the cells. The minimum daily protective dose for guinea pigs has been found to be from 0.6 to 1 mg for the reducing principle, and is stated to be about 1 mg for hexuronic acid.

Structural formulas for hexuronic acid and the two oxidized forms are given as follows: Hexuronic acid— $\text{CH}_2\text{OH.CO.CHOH.CHOH.CHOH.COOH}$; reversible oxidized hexuronic acid— $\text{CHO.CO.CHOH.CHOH.CHOH.COOH}$; and irreversible oxidized hexuronic acid— $\text{COOH.CO.CHOH.CHOH.CHOH.COOH}$. It is noted, however, that the proposed formula may not apply to the crystalline form, which probably contains the lactone grouping with the splitting off of a molecule of water. Inability to obtain crystals from the reducing substance is attributed to the failure as yet to obtain the substance in the lactone form.

The non-specificity of the phenolindophenol reducing capacity of lemon juice and its fractions as a measure of their antiscorbutic activity, S. S. ZILVA (*Biochem. Jour.*, 26 (1932), No. 5, pp. 1624-1627).—In this reply to the various papers of Tillmans et al. leading to the conclusion that the phenolindophenol reducing capacity of plant materials is due to vitamin C itself, a comparison is reported of the reducing capacity of phenolindophenol and the antiscorbutic potency as determined on guinea pigs of a large number of samples of dehydrated lemon juice used in the author's extensive research on vitamin C over a period of five years (E.S.R., 66, p. 113).

The data, as grouped by increasing reducing values, showed no consistent relationship. With the solutions of highest reducing value little or no antiscor-

butic protection was obtained in five tests involving about 15 guinea pigs. At the other extreme a fair degree of protection was obtained in three tests comprising about 9 guinea pigs on daily doses showing low reducing capacity.

Narcotine as the alleged precursor of vitamin C, R. L. GRANT, S. SMITH, and S. S. ZILVA (*Biochem. Jour.*, 26 (1932), No. 5, pp. 1628-1632, pl. 1).—A further refutation of the results obtained by Rygh and his collaborators is reported in the attempted isolation of narcotine from the juice of unripe oranges, the attempted preparation of an antiscorbutic concentrate from lemon juice by the method of Rygh et al. (*E.S.R.*, 67, p. 648), and in the examination of methyl nornarcotine for antiscorbutic activity. Two tests with methyl nornarcotine were reported, in one of which the material was prepared under strictly anaerobic and in the other less strictly anaerobic conditions. The substances were subjected to chemical as well as biological tests. In all of the tests negative results were obtained. Attention is called in a footnote to the fact that there is no evidence that unripe fruits or vegetables have a lower vitamin C concentration in their juices than ripe ones.

The vitamin C activity of hexuronic acid from suprarenal glands, W. A. WAUGH and C. G. KING (*Science*, 76 (1932), No. 1983, p. 630).—This is a brief note announcing that hexuronic acid prepared by E. C. Kendall from suprarenal glands by a different procedure from that followed in the author's laboratory (*E.S.R.*, 67, p. 649) corresponded with their own product in crystalline form, melting point, reducing value, titration equivalent, and rotatory power, and in biological activity. The minimum protective dose was slightly over 0.5 mg daily. "The procedure for isolating the hexuronic acid from suprarenal glands involved an ether extraction of the solution when neutralized by sodium bicarbonate. This would have removed such a substance as the σ -diphenol derivatives of narcotine, which has been considered by Rygh to be identical with vitamin C."

Chemical investigations on the antiscorbutic vitamin, III [trans. title], O. and A. RYGH (*Hoppe-Seyler's Ztschr. Physiol. Chem.*, 211 (1932), No. 6, pp. 275-284, fig. 1).—In continuation of the series noted previously (*E.S.R.*, 67, p. 648), a theory reconciling the antiscorbutic activity of methyl nornarcotine and the hexuronic acid of Szent-Györgyi is proposed on the basis of observations that in guinea pigs on a scorbutic diet glucuronic acid gradually disappeared from the urine, and that while the addition of 0.5 mg of glucuronic acid to the scorbutic diet did not prevent scurvy, the further addition of traces (0.01 mg of a 30 percent solution) of methyl nornarcotine to the same amount of glucuronic acid afforded protection against scurvy and promoted normal growth in litter-mate controls. It is also noted that methyl nornarcotine alone has cured severe cases of human scurvy.

These findings are thought to indicate that antiscorbutic activity is due to a combination of glucuronic acid with methyl nornarcotine. In man external sources of glucuronic acid are not required, while they are in the guinea pig. The hexuronic acid of Szent-Györgyi is assumed to be glucuronic acid, together with a trace of methyl nornarcotine which accompanies it throughout the various steps of the purification process. The occasional solubility in ether of the vitamin C of fruit juices is explained on the ground that, although free methyl nornarcotine is insoluble in ether, its compound with glucuronic acid is somewhat soluble.

Methylnornarcotine, glycuronic acid, and vitamin C, W. J. DANN (*Nature [London]*, 131 (1933), No. 3297, pp. 24, 25).—A preliminary note reporting failure to confirm observations of Rygh and Rygh noted above.

Crystalline structure of hexuronic acid, E. G. COX (*Nature [London]*, 130 (1932), No. 3275, pp. 205, 206).—A brief description is given of the crystalline

structure of hexuronic acid as determined by X-ray examination by the single crystal rotation method. Purified crystals proved to be identical with the crystalline portion of the original substance as isolated by Szent-Györgyi (E.S.R., 67, p. 645). The crystalline properties are such as to suggest that "the hexuronic acid molecule has a ring structure with fewer groups projecting out of the plane of the ring than a normal carbohydrate and contains double bonds, possibly in carbonyl groups."

Hexuronic acid as the antiscorbutic factor, E. G. COX, E. L. HIRST, and R. J. W. REYNOLDS (*Nature [London]*, 130 (1932), No. 3293, p. 888).—In this further note on the chemical behavior of the hexuronic acid of Szent-Györgyi, the authors propose the following structural formula as best accounting for the observed properties: $\text{CH}_2\text{OH}.\text{CHOH}.\text{CH}_2\text{CO}.\text{CO}.\text{COOH}$. It is thought that the substance can react in the enol modification $\text{CH}_2\text{OH}.\text{CHOH}.\text{CH}:\text{COH}.\text{CO}.\text{COOH}$.

"Hexuronic acid" (ascorbic acid) as the antiscorbutic factor, A. SZENT-GYÖRGYI and W. N. HAWORTH (*Nature [London]*, 131 (1933), No. 3297, p. 24).—The authors propose the name ascorbic acid for the crystalline substance $\text{C}_6\text{H}_8\text{O}_6$ hitherto designated as a hexuronic acid. The reasons given for this change are that " (1) hexuronic acid is the name of a class of substances rather than that of one individual compound, and that (2) the material described as hexuronic acid isolated from adrenal cortex and now from paprika contains a molecule of water less than is required for a hexuronic acid."

Ascorbic acid as vitamin C (*Lancet [London]*, 1933, I, No. 9, p. 484).—In this editorial comment, attention is called to the similarity between the present claim that the hexuronic acid of Szent-Györgyi, ascorbic acid, is the antiscorbutic vitamin and the earlier claims with regard to cholesterol and carotene as the provitamins for vitamin D and vitamin A, respectively. It is noted that the verdict was not the same in the two earlier cases, but that the consensus of opinion is that ascorbic acid is identical with vitamin C. A further comparison is made between the failure in attempts to isolate vitamin A in a comparatively pure state until a richer source than cod-liver oil had been found in the form of halibut-liver oil and similar difficulty in obtaining sufficient ascorbic acid from adrenal glands in comparison with the ease with which a large quantity has been prepared recently from a newly discovered rich source of the vitamin, a Hungarian red pepper (*Capsicum annuum*).

The phosphorus content of casein.—Preliminary paper, R. E. L. BERGGREN (*Jour. Biol. Chem.*, 95 (1932), No. 2, pp. 451-460, figs. 3).—The preliminary experiments reported upon were designed to indicate whether or not the phosphorus content of a casein preparation is influenced by the phosphate content of the milk from which the protein is precipitated. The phosphorus-nitrogen ratio was shown to be 0.0522 and 0.0558, respectively, in two preparations of which the first was made by adding dilute hydrochloric acid to the fresh milk until the isoelectric point (pH 4.6) was reached, the second by leaving the milk in the refrigerator until casein separation was complete as a result of souring; whereas two casein preparations obtained by first dialyzing the milk against distilled water in a refrigerator for 12 days in a collodion membrane (thymol as preservative), with subsequent precipitation by adding hydrochloric acid to bring the pH to 4.6, had the phosphorus-nitrogen ratios 0.0444 and 0.0215.

The application of the Fiske-Subbarow colorimetric method to the determination of phosphorus in casein, R. E. L. BERGGREN (*Jour. Biol. Chem.*,

95 (1932), No. 2, pp. 461-464).—The author weighed quantities approximating 1.5 g. of casein into 100-cc volumetric flasks, and dissolved these samples by adding to each 30 cc of 0.1 N sodium hydroxide and diluting the resulting solutions to volume. One cc aliquots from such solutions were evaporated to dryness and **ashed at just a red heat in platinum**, treated with a few drops of water and one drop of saturated magnesium nitrate solution, and again evaporated and ignited. After due precaution to insure the absence of nitrites, the Fiske-Subbarow method (E.S.R., 55, p. 310) was applied to the solutions of the ash thus prepared.

An average of the results obtained with nine different casein preparations gave 0.8 percent phosphorus by the colorimetric method and 0.805 percent by the gravimetric method.

A new color test for cysteine, E. DYER and O. BAUDISCH (*Jour. Biol. Chem.*, 95 (1932), No. 2, pp. 483-489).—The authors show that the appearance of a red color in the chloroform layer when an aqueous solution of cysteine hydrochloride is shaken with a chloroform solution of *o*-benzoquinone furnishes a simple specific test for cysteine. This reaction may be used for detection of cysteine in the presence of cystine, glutathione, and many other sulfur and nitrogen compounds, and its application as a test for cystine by first reducing it to cysteine was also shown to be practicable.

The electrometric determination of chlorides in soils by the silver-silver chloride electrode, E. F. SNYDER (*Soil Sci.*, 35 (1933), No. 1, pp. 43-48).—Having outlined the theoretical basis for the titration of the chloride ion with the silver-silver chloride electrode in combination with a quinhydrone reference electrode as indicator, the author of this contribution from the U.S.D.A. Bureau of Chemistry and Soils prescribes a procedure essentially as follows:

Place in a 150-ml beaker 5 g of soil, passing a 50-mesh sieve, and 50 ml of distilled water. Increase the sample to 10 g for small quantities of chlorine and decrease for large quantities. Of a soil extract make up an aliquot to approximately 50 ml with distilled water. Let the Ag-AgCl electrode and agar bridge reach nearly to the bottom of the beaker and stir the suspension continually by means of an electric stirrer during the determination. Add dropwise to the suspension or extract sufficient sulfuric acid (1+2) just to redden a strip of thymol blue paper, about pH 2, and maintain this reaction. At the end of 10 minutes close the circuit momentarily and observe the galvanometer deflection, from which an approximation may be had of the volume of N/35.457 silver nitrate required. "During the course of a titration, particularly on the soil extract, it may be necessary occasionally to wash the electrode free from any adhering silver chloride." Add silver nitrate, with subsequent adjustment of the potentiometer, until the galvanometer deflection just reverses, indicating the end-point. "It is desirable to continue the determination 5 minutes longer to be sure the end-point is constant. The silver nitrate solution is made up as N/35.457 so that 1 ml is equivalent to 1 mg of chlorine. An N/35.457 potassium chloride solution may be used for back titration if necessary."

A method for determining the quantity of mineral oil retained by leaf surfaces after spraying, L. H. DAWSEY and A. J. HAAS, JR. (*Jour. Agr. Res.* [U.S.], 46 (1933), No. 1, pp. 41-49, figs. 2).—The oil left on camphor leaves after spraying with emulsions containing highly purified mineral oil was removed from a number of disks of known area by solution in ether, the natural leaf oils and waxes dissolved with the mineral oil being destroyed by treatment with nitric acid, after which the mineral oil was measured in calibrated Babcock skim milk bottles. With certain variations the method was applicable to pecan and Satsuma orange leaves. The maximum error was found to be less than 1 percent in the case of pecan leaves and less than 2.5 percent with camphor and orange leaves. An example shows residues varying

from 0.1 to 0.24 mg per square centimeter after the use of various emulsions, in which the oil concentration was kept constant at 1.6 percent but the emulsifier concentration ranged from 0.003 to 0.0004 N sodium oleate.

AGRICULTURAL METEOROLOGY

Agricultural meteorological scheme.—Bibliography of literature on agricultural meteorology, Sects. 1-4 (London: Min. Agr. and Fisheries, [1931], sects. 1, pp. [88]; 2, pp. [320]; 3-4, pp. 123+17).—This mimeographed document gives all available summaries and extracts of literature dealing with agricultural meteorology and allied subjects which have appeared in the crop weather reports of the British Ministry of Agriculture and Fisheries from the inception of the Agricultural Meteorological Scheme (E.S.R., 62, pp. 403, 611) in 1924 to the end of September 1930, with author and subject indexes.

Meteorology. E. V. NEWMHAM (*Sci. Prog.* [London], 27 (1932), No. 106, pp. 237-244).—This is a critical review, mainly of Köppen's classification of climates.¹ The classification is stated to be based primarily on temperature and rainfall and the seasonal variation of these two elements as related to typical soils and vegetation, and is referred to as "probably the one most often used in investigations into the agricultural possibilities of different parts of the world." [The classification takes little account of sunlight as a climatic factor.]

The moon and weather forecasting [trans. title], J. ROUGH (*Rev. Sci.* [Paris], 71 (1933), No. 2, pp. 48, 49).—This article refers briefly to observations by J. Bertho on the island of Réunion and in the surrounding regions, from which he developed a method of forecasting weather (cyclones) based on phases and declination of the moon and its distance from the earth. A high degree of accuracy of the method is indicated.

What will the winter be? (*Bul. Amer. Met. Soc.*, 14 (1933), No. 1, pp. 17, 18).—Reference is made to a typewritten report on a study by J. R. Weeks of the 115-year weather records of Baltimore and Philadelphia, from which the reviewer concludes that "an annual forecast for the coming winter would be impossible, for the verification would be entirely too small, but the correlation could and should be used when autumn or October or summer departures are sufficiently large."

World weather. V. G. T. WALKER and E. W. BLISS (*Mem. Roy. Met. Soc.*, 4 (1932), No. 36, pp. 53-84, figs. 19; abs. in *Sci. Abs.*, Sect. A—Phys., 36 (1933), No. 422, pp. 132, 133).—A study, the fifth of a series (E.S.R., 63, p. 415), of variations in the so-called North Atlantic, North Pacific, and southern oscillations as related to pressure, temperature, and rainfall over wide regions, as well as to sun spots, is reported. It was found that the southern oscillation in the southern winter is extremely persistent and its departure has a correlation coefficient of 0.84 with that of the following summer, thus providing a possible basis for forecasting seasonal conditions. The effects of Antarctic conditions and of ocean temperatures are considered, but without conclusive results as to the physical basis for the oscillations.

Climatological summary for Wooster and Ohio for the year 1931. C. A. PATTON (*Ohio Sta. Bul.* 516 (1933), pp. 123-128).—Data for temperature, precipitation, and length of the growing season at the experiment station, Wooster, and for the State at large, for 1931, are summarized as for previous years (E.S.R., 67, p. 12).

¹ Grundriss der Klimakunde. Berlin: Walter de Gruyter & Co., 1931, pp. XII+366, pla. 9, figs. 28.

A detailed study of desert rainfall, R. R. HUMPHREY (*Ecology*, 14 (1933), No. 1, pp. 31-34, figs. 2).—Results of a detailed study of variations in rainfall during the year ended August 28, 1931, with rain gages distributed at 100-m intervals on a relatively small area on the grounds of the Desert Laboratory of the Carnegie Institution of Washington, at Tucson, Ariz., are briefly summarized. It was observed that the mean annual rainfall varied for almost all of the gages, in some cases widely. This is attributed, however, to great local variations in certain of the heaviest showers rather than consistent differences in precipitation. A slight but progressive increase of rainfall with increasing altitude was observed up to 600 ft. above the plain. Winter rains tended to be more uniform, of longer duration, and less intense than summer rains. The area on which the observations were made included both level and sloping land.

Temperature of air layers near the soil [trans. title], H. KARSTEN (*Acta Agr. Fennica*, No. 26 (1932), pp. 71, figs. 22).—Previous investigations are reviewed, and studies made by the author in 1931 at Perkkjarvi, in Finland, are reported in detail. The report is of special interest from the standpoint of methods of collecting, analyzing, charting, and interpreting the data and for its discussion of the complex character of the problem, which makes reliable conclusions difficult.

Storm injuries [trans. title], H. BURGER (*Mitt. Schweiz. Centralanst. Forstl. Versuchsw.*, 17 (1932), No. 2, pp. 341-376, pls. 6, figs. 8).—Storm injuries to forest growth in Switzerland during the past 50 years, particularly those caused by winds, are summarized and discussed. It is stated that during the 50 years covered by this study about 3,000,000 m³ of timber has been thrown down by the wind, and that this windfall has contributed from 2 to 2.5 percent of the forest growth used annually. The general wind conditions, some of the more destructive storms, and characteristic injuries are described.

The influence of climatic factors on the variations of yield [trans. title], F. ENQUIST (*Svensk Geogr. Årsbok*, 1932, pp. 122-146, figs. 12; *Eng. abs.*, pp. 144-146).—The results of a statistical study of yearly, secular, and geographic variations in weather and climate in Sweden and other European countries as related to yield of crops, particularly Swedish Velvet Chaff wheat, are given in this article. Among the conclusions reached by the author is that in spite of man's efforts through soil improvement, plant breeding, and similar means to bring about systematic consecutive improvements in crop yields, changes in the climatic condition of different regions remain the decisive factor.

SOILS—FERTILIZERS

A quarter century progress in soil science, J. G. LIPMAN (*Jour. Amer. Soc. Agron.*, 25 (1933), No. 1, pp. 9-25).—This contribution from the New Jersey Experiment Stations (E.S.R., 68, p. 427) reviews among other topics, the historical background; the origin, formation, and classification of soils; soil surveys, classification, and mapping in the United States; some European soil surveys and maps; soil chemistry, including soil acidity, base exchange, and soil colloids; soil microbiology; plant nutrition; soil erosion; lysimeter investigations; and field plots.

Methods for the examination of the soil [trans. title], edited by O. LEMMER-MANN (*Ztschr. Pflanzenernähr., Düngung u. Bodenk.*, Sup. 1 (1932), pp. 90, figs. 2).—Following a brief introduction and a list of the contributing institutions, this collection of methods contains the sections (a) the taking of soil samples, (b) the physical examination of mineral and humus soils, (c) the examination of mineral soils, (d) the examination of moor lands and similar

soils, and (e) the examination of forest soils. Each of the first four sections is subdivided into various groups of determinations and tests, while the last-named section takes up only the chemical examination of forest soils.

Petrographic methods for soil laboratories, W. H. Fay (*U.S. Dept. Agr., Tech. Bul. 344* (1933), pp. 96, figs. 5).—Following an introduction dealing briefly with some of the general bases of microscopic crystallography and some related matters, the bulletin has the further main divisions of crystal form, fundamental properties of light, the petrographic microscope and accessories, optical methods, and application of methods. An appendix tabulates the optical properties of numerous examples of isotropic substances, uniaxial positive substances, uniaxial negative substances, biaxial positive substances, and biaxial negative substances.

[**Soil Survey Reports, 1928 Series**] (*U.S. Dept. Agr., Bur. Chem. and Soils [Soil Survey Rpts.]*, Ser. 1928, Nos. 25, pp. 60, pls. 3, fig. 1, maps 2; 26, pp. 38, fig. 1, map 1).—The two survey reports here noted were prepared with the cooperation, respectively, of the Massachusetts Department of Agriculture and the Ohio Experiment Station.

No. 25. *Soil survey of Hampden and Hampshire Counties, Massachusetts*, W. J. Latimer and L. R. Smith.—Hampden and Hampshire Counties, Mass., possess a combined area of 771,200 acres in the southwestern part of the State, their lands forming a rather uneven, much dissected plateau divided about midway by the broad Connecticut Valley lowland which runs north and south across the combined area. Most of the numerous soil types have well established drainage.

So large a variety of soils is represented in this area that of the 43 types of 26 series mapped and described the most extensive, Gloucester stony fine sandy loam, embraces only 8.1 percent. Among miscellaneous soils 7.4 percent of meadow, muck, and peat, together with 19.5 percent of rough stony land, which "furnishes much of the timber and cordwood cut within the area", were found.

No. 26. *Soil survey of Ottawa County, Ohio*, A. H. Paschall et al.—Ottawa County lies against the northern border of Ohio and has an area of 167,680 acres of lands showing in general a nearly level to gently rolling surface, covered mainly by soils of 16 series and 30 types with smaller areas of some miscellaneous soils. Of these soils, Toledo silty clay, highly productive when tile drained where artificial drainage is needed, and Fulton silty clay loam occupy 45.7 and 10.6 percent, respectively, of the total area of the county.

[**Soil Survey Reports, 1929 Series**] (*U.S. Dept. Agr., Bur. Chem. and Soils [Soil Survey Rpts.]*, Ser. 1929, Nos. 7, pp. 26, fig. 1, map 1; 8, pp. 21, fig. 1, map 1).—These surveys were in cooperation with the Maryland Experiment Station.

No. 7. *Soil survey of Caroline County, Maryland*, H. B. Winant and S. R. Bacon.—Caroline County is an area of flat, undulating, and gently rolling lands, with short steep slopes bordering the larger streams, amounting to 204,160 acres and lying on the eastern border of Maryland. Although the central and southwestern parts of the county have in general an adequate drainage, other sections are more or less in need of drainage.

Sassafras loamy sand, Sassafras sandy loam, Sassafras loam, and Elkton loam, 20.2, 19, 13.3, and 10.6 percent, respectively, of the entire county are the more extensive soils among 15 types of 5 series. There is 5 percent of meadow and 2.2 percent of tidal marsh.

No. 8. *Soil survey of Talbot County, Maryland*, S. O. Perkins and M. Hershberger.—Talbot County is a tract of 171,520 acres of generally flat plain of which more than 30 percent has poor drainage.

The most extensive of the 9 types, here assigned to 3 series, is a silt loam of the ill-drained Elkton series amounting to 26.3 percent of the county. Keyport silt loam constitutes 20.5, and Sassafras loam 16.4 percent. There is 2.9 percent of meadow and 2.8 percent of tidal marsh.

[**Soil investigations of the California Station**] (*California Sta. Rpt. 1932, pp. 37-39, 52-55, fig. 1*).—Experimental work on the need of phosphorus and on alkali problems is very briefly summarized. The report contains also short items on a soil utilization and land-appraisal index, on subsidence of peat lands, and irrigation studies.

[**Soil and fertilizer investigations of the Delaware Station**], H. C. HARRIS, P. B. MYERS, G. M. GILLIGAN, and T. F. MANNS (*Delaware Sta. Bul. 179 (1932), pp. 18-20, 26, 27, 55*).—The soil investigations here reported upon include a study of the H-ion concentration of soils as controlled by applications of sulfur or lime, and of soil buffer action; work on the colloidal fraction of a subsoil from the standpoint of its electrodialyzable bases; and an investigation into the effect of copper, manganese, and iron on nitrogen fixation.

[**Soil utilization tests in Georgia**] (*Georgia Coastal Plain Sta. Bul. 19 (1932), pp. 98-100*).—Work of the Coastal Branch Station at Darien is discussed under the heads of soil type, soil management, cover crop tests, and rates and frequency of application of lime.

[**Soil and fertilizer investigations at the Indiana Station**] (*Indiana Sta. Rpt. 1932, pp. 18, 19, 55, 65, 66, 67, fig. 1*).—Report is made upon studies of the Neubauer method for determining the fertilizer needs of soils for crop plants, greenhouse comparisons of superphosphate and raw rock phosphate, and on yields and financial returns from various fertilizer treatments on the various experimental fields. Mention is made also of the performance of approximately 2,000 insoluble phosphoric acid determinations to ascertain the effect of the type of filter paper used upon the results of this determination.

[**Studies on soil problems at the Iowa Station**], P. E. BROWN ET AL. (*Iowa Sta. Rpt. 1932, pp. 73-89, fig. 1*).—Brief notes are given on findings from experiments on the effects of fertilizers on crops and soil conditions under various rotations in the Wisconsin drift soil area; the effects of fertilizing materials and methods of grazing on soil conditions and plant growth on permanent pastures; the effects of various amounts of fertilizers applied at different times in the rotation on the crops and soil conditions in the Wisconsin drift soil area; effects of various amounts of limestone of different degrees of fineness on the Tama silt loam; the relative value of red clover, alfalfa, and sweetclover as soil building crops; response of various soil types to treatments in the greenhouse; the effects of various fertilizing materials on crop growth on various soil types; the value of commercial cultures for the inoculation of legumes and nonlegumes; the fixation of atmospheric nitrogen by nonsymbiotic micro-organisms; nitrification in Iowa soils; the effect of fertilizers and various soil treatments on micro-organisms; nitrate assimilation in soils; the occurrence and activities of soil fungi in Iowa soils; the physiological characteristics of *Rhizobium*; the effect of lime and legume inoculation on crops and on soil conditions in southern Iowa; the plant food content and lime requirements of Iowa soils and the composition of various crops; base exchange in Iowa soils; the available phosphorus in Iowa soils; and the formation of humus and the decomposition of organic matter in soils.

[**Soil investigations of the New York Cornell Station**] (*New York Cornell Sta. Rpt. 1932, pp. 92-95*).—Data are given on physicochemical studies of muck soils, a study of unproductive muck, and mull and duff as biotic equilibria.

[**Soil and fertilizer investigations of the Ohio Station**], R. M. SALTER, C. J. SCHOLLENBERGER, J. W. AMES, R. BRADFIELD, G. W. CONREY, J. G. STEELE,

T. C. GREEN, F. G. LOUGHRY, H. W. BATCHELOR, and J. BUSINELL (*Ohio Sta. Bul. 516 (1933)*, pp. 30, 31-33, 34, 35, 64, 65, fig. 1).—Data are reported briefly on impurities and the agricultural value of limestone, unusual accumulation of soil nitrates in 1931, the measurement of size frequency distribution in soils, some physical factors affecting the determination of the number of nitrogen-fixing bacteria in soil, and corn and rye as green manures.

Single value soil properties of tropical soils, J. CHARLTON (*Indian Jour. Agr. Sci.*, 2 (1932), No. 1, pp. 62-85).—The existence of a high correlation between the stick point moisture (S) and loss on ignition (I) was confirmed, the values found for 'SI and partial correlations approximating those found by Coutts (E.S.R., 64, p. 418) for 66 South African soils. Among the soil properties examined, it seems unlikely that any correlation except 'SI could be regarded as relatively free from the influence of replaceable bases or other factors. Even in the case of 'SI, certain factors were found to have an influence on the correlation.

"Although high correlations were found for 'SC and 'RI [C=clay content; R=moisture content of the soil when at equilibrium with a 50 percent moisture-saturated atmosphere], such relationships do not indicate a fundamental direct relationship in all cases when examined by partial correlations. There is little doubt, for instance, that clay percent and sticky point moisture may be inversely related in certain soils. It is believed that the variability of the relationship between clay percentage and sticky point moisture is largely controlled by the replaceable bases, although other factors may be important also."

The increase in the value of 'SC as a result of treatment by H_2O_2 was found to be small, whereas Keen and Coutts (E.S.R., 63, p. 510) found a large increase. This result is ascribed to the low organic matter content of the Burma soils, those examined by Keen and Coutts being supposed to contain organic matter in larger amount. "In normal arable tropical soils it follows that the sticky point moisture is largely controlled by the inorganic colloids." Experimentally it was found that the nature of the replaceable bases exercised a very large effect on the value of the sticky point moisture, but as the ignition loss was somewhat similarly affected by change of replaceable base, the correlation SI remained high. No evidence of an increased value for the correlation 'CI as a result of H_2O_2 treatment or with increased depth (diminished organic matter) was found.

With only one replaceable base present, the total correlations 'SI and 'RI were approximately perfect. Of this observation it is noted that "this indicates that even if the silica/sesquioxide ratio of soils affects the values of S, I, and R, it probably has smaller effect than change of replaceable base. On the other hand the soils worked with were from an area where the silica/sesquioxide ratio may be expected to be reasonably constant, so that soils from different types may be expected to give lower correlations even with only one replaceable base present."

A study of the physico-chemical changes accompanying the process of reclamation in alkali soils, D. SINGH and S. D. NIJHAWAN (*Indian Jour. Agr. Sci.*, 2 (1932), No. 1, pp. 1-18, pl. 1, figs. 2).—The authors consider that to improve sodium clay soils the first essential is to convert sodium clay into calcium clay with the help of calcium salts. Leaching and drainage of such soils cannot alone bring about any permanent cure, and may in the long run do more harm than good.

"The extent of kallar trouble in such soil is measured by a ratio of sodium to calcium or a ratio between the monovalent and divalent bases present in the exchange complex. The amount of calcium salts required for the reclama-

tion of such soils depends on the sodium present in the exchange complex. The dispersion coefficient may furnish as a ready method for determining the relative amounts of exchangeable calcium and sodium in the kallar soils. With the help of calcium salts followed by a treatment of farmyard manure it is possible to improve the bari soil to the status of a normal soil."

Changes in volume that occur when dry soils are wetted with water and with chemical solutions, G. BOUYOUCOS (*Jour. Amer. Soc. Agron.*, 25 (1933), No. 2, pp. 129-133, fig. 1).—In the experiments reported upon in this contribution from the Michigan Experiment Station the original or absolute volume of the oven-dry soils and liquids considered together decreased when the soils were brought into intimate contact with the liquids, the volume contraction being greatest in clays and in soils with a high content of organic matter. With the exception of that in potassium hydroxide solution, the volume contraction of any given soil in all the chemical solutions used was the same as that in water. That in the potassium hydroxide was much less.

The volume contraction appeared to be due to the compression of the water adsorbed by the soils. Further, "when soils are saturated with water or chemical solutions and swell and increase in volume, this increase in volume is only apparent and not real. In the real volume there is a decrease."

Solubility of the solid phase of soil in water, S. M. DRACHEV (*Soil Sci.*, 35 (1933), No. 1, pp. 75-83, figs. 2).—The author determined by an electrolytic conductivity method the quantities of soluble compounds in two series of extracts of carbonate- and gypsum-free chernozem, podsol, and gray forest soils, the soil-water ratios used respectively in the two sets of experiments being (a) 1:1, 1:4, 1:10, 1:20, and 1:100; and (b) 1:4, 1:8, 1:16, 1:32, 1:64, and 1:128.

"Between the volume of the solvent and the quantity of electrolytes exists a functional relation which can be expressed by the equation, $x=y\sqrt{V+b}$, where x represents the quantity of soluble electrolytes in milliequivalents in 100 g absolutely dry soil, V the ratio between the volume of dissolvent and the weight of soil, b the quantity (in milliequivalents) of easily soluble salts extracted from the soil by a small volume of water, y constant. The value of the constant (y) for chernozem fluctuated from 0.68 to 2.03, for podsol from 0.04 to 0.34." Observed and calculated data are tabulated. The data on sodium carbonate and humus extracted from solonetz soil with successively increasing water volumes were in agreement with the calculated values.

"The study of the solubility of phosphate minerals (apatite, phosphate rock) in water shows that the solution of these minerals to some extent follows the same rule. The constant (y) of the solubility of apatite was about the same as that of the podsol soil."

Soil acidity as a phytopedological factor, A. I. POTAPOV (*Soil Sci.*, 35 (1933), No. 1, pp. 55-73, figs. 2).—The author presents "a rough outline of a phytopedological classification in which the plant and soil are embodied in definite classes, each class having definite indexes of average normal conditions of correlations of the plant and soil", together with "examples . . . of the dynamics of phytopedological processes and methods of determining the phase into which the said process has entered together with its trend."

Base interchange induced by calcium, magnesium, and sodium nitrates in a 6-foot column of soil-subsoil, W. H. MACINTIRE, J. B. YOUNG, and W. M. SHAW (*Soil Sci.*, 35 (1933), No. 1, pp. 49-53, fig. 1).—Triplicated single, heavy, equivalent additions of sodium, calcium, and magnesium nitrates were made at the Tennessee Experiment Station to Cumberland clay loam underlaid by 5 ft. of red clay subsoil, and the outgo of bases was determined annually for a period of 9 years in 12 lysimeters.

"The replacements of calcium and magnesium by sodium were decidedly less than the reciprocal calcium-magnesium replacements shown for the two divalent nitrates. The amounts of calcium recovered from calcium nitrate and exchanged by the magnesium of magnesium nitrate were practically the same. Conversely, the recovered and exchanged quantities of magnesium from magnesium nitrate and calcium nitrate, respectively, were in close agreement. The amounts of potassium replaced by the heavy additions of sodium, calcium, and magnesium nitrates were so small as to indicate that the amounts of potassium made available by ordinary amounts of nitrates would be inconsequential."

Base-exchange modifications of a Leonardtown silt loam under fertilizer and crop control. R. S. HOLMES (*Jour. Agr. Res. [U.S.]*, 46 (1933), No. 2, pp. 161-168, fig. 1).—Chemical and physical determinations upon productive plats of Leonardtown silt loam, on which fertilizer treatment tests had been carried on for 12 years were made by the author of this contribution from the U.S.D.A. Bureau of Chemistry and Soils to determine any modifications produced in the soils by the fertilizers applied. On measuring base exchange the 0.05 N HCl and normal $\text{NH}_4\text{C}_2\text{H}_3\text{O}_2$ methods gave approximately the same results for the mono- and dibasic constituents, though Fe, Al, and P were appreciably soluble in 0.05 N HCl but practically insoluble in $\text{NH}_4\text{C}_2\text{H}_3\text{O}_2$. The above determinations show that the fertilizer treatments increased the average available P, K, Mn, Mg, and Ca and total N content of the treated plats. The results also indicate that this soil contains in its normal state adequate plant food supplies except in the case of phosphorus.

Preliminary studies of the exuded plant sap and the relation between the composition of the sap and the soil solution. W. H. PIERRE and G. G. POHLMAN (*Jour. Amer. Soc. Agron.*, 25 (1933), No. 2, pp. 144-160).—Determinations of pH, specific resistance, and of phosphorus, calcium, nitrate nitrogen, silica, and chlorides were made at the West Virginia Experiment Station on a number of samples of sap obtained by cutting the stalk of plants near the surface of the ground and collecting the sap which exuded from the stump ends, together with a study of the relation between the concentration of various elements in the plant sap and in the soil solution obtained from the soils upon which the plants were growing. Other experiments included work on the composition of the plant sap of corn, sorghum, and Sudan grass as affected by three different degrees of soil acidity and determinations of the composition of sap samples collected on successive days.

The sap of corn was found to contain an average concentration of about 3,700 p.p.m. total solids, of which approximately one third was apparently in the inorganic form. The total phosphorus content of the sap of corn, sorghum, and Sudan grass was found to range between about 150 and 450 p.p.m. PO_4 . Of this concentration generally over two thirds and in some cases all were found to be in the inorganic form. The concentration of silica in the plant sap was found to average about 250 p.p.m., of calcium about 80 p.p.m., and of chlorides about 90 p.p.m., while nitrates were found to vary from a trace to 344 p.p.m.

Samples of sap from the same plants collected on successive days were found to remain quite constant in total phosphorus for a period of four days. The inorganic phosphate, however, was found to increase as bleeding proceeded, while the organic phosphate tended to decrease. Chlorides were found to increase in the sap as bleeding continued, but calcium and silica were not found to show any consistent variations.

The pH values of the sap of corn, sorghum, and Sudan grass were found to be about the same, varying from about 4.4 to 4.8. Differences in soil acidity

from pH 4.6 to 6.6 were not found to affect the acidity of the sap of any of the three species. The H-ion concentration of the soil was not found to affect the concentration of calcium, phosphorus, and chloride in the plant sap within a range of pH 4.6 to 6.6. With increased pH values of the soil a slightly greater concentration of silica was found in the plant sap. The total electrolyte content of the sap of corn, as measured by conductivity determinations, was found to be less in nearly all cases than that of the displaced soil solution. Phosphorus and silica were found in much higher concentrations in the plant sap than in the displaced soil solution, "the concentration factor" for the former ranging from 552 to 4,967 and for the latter from 15.2 to 34.8. On the other hand, chlorides and calcium were found in considerably lower concentrations in the plant sap than in the soil solution. Nitrates were higher in some cases and lower in others in the plant sap than in the displaced soil solution. The data appeared to indicate that there may be a correlation between the concentration of phosphorus in the plant sap and that in the soil solution and soil extract.

The phosphorus concentration of the exuded sap of corn as a measure of the available phosphorus in the soil, G. G. POHLMAN and W. H. PIERRE (*Jour. Amer. Soc. Agron.*, 25 (1933), No. 2, pp. 160-171).—The results obtained under greenhouse conditions at the West Virginia Experiment Station appear to have shown a good correlation with the response of corn to phosphate fertilization and also with the water-soluble PO_4 and the available PO_4 as determined by the Truog method (E.S.R., 64, p. 312). They are compared also with those obtained at the Rhode Island Experiment Station (E.S.R., 57, p. 812) by Gilbert and Hardin, using expressed juice. The present authors state that it is easier to collect and analyze exuded juice. The proportion of inorganic phosphate (as PO_4) is reported as varying in the corn sap examined from 62 to 602 p.p.m., the proportion usually increasing with the age of the plant.

It is further stated that "the data seem to justify additional tests with the method in order to ascertain limiting concentrations of PO_4 for normal growth. Certain factors, such as light, temperature, moisture condition of the soil, supply of other nutrients, age and metabolic condition of the plant, and height of cutting, may affect the results and these should be considered in further studies of the method.

"Although no data are presented in this paper to show the concentrations of other nutrients in the exuded sap it would appear that the method might be used to advantage in a study of the availability of various elements, particularly nitrogen and potassium."

The easily soluble phosphorus content of soil as determined by electro-dialysis, extraction with dilute acid solutions, and crop response to fertilization, H. J. HARPER (*Soil Sci.*, 35 (1933), No. 1, pp. 1-16, figs. 9).—Soils obtained from Rhode Island, New Jersey, Ohio, Indiana, Iowa, Oklahoma, and other States were studied at the Oklahoma Experiment Station with reference to the relation between the quantity of phosphorus removed from the soil by electro-dialysis or by treatment with dilute acid and the crop response of phosphatic fertilizers. Electro-dialysis removed a large percentage of the easily soluble phosphorus content of the average soil in a 3-hour extraction. It was found that the iron and aluminum phosphates were less soluble by electro-dialysis than the calcium phosphates. Apatite, triplite, and quercyte were less soluble than chlorapatite, collinsite, collophanite, and griphite. Dufrenite, wavellite, and vivianite were the least soluble of the minerals studied. The amount of the phosphorus removed by electro-dialysis correlated closely with the response of crops to phosphorus fertilization.

In most cases soils containing more than 30 p.p.m. of easily soluble phosphorus did not respond to phosphorus fertilization. Very few soils produced a

marked response from phosphorus fertilization when the easily soluble phosphorus shown by the Truog method (E.S.R., 64, p. 312) was above 20 p.p.m. The Bray method (E.S.R., 62, p. 13) for easily soluble phosphorus was not as accurate as the other quantitative methods. It was found that a lack of easily soluble iron in the soil was frequently responsible for the appearance of doubtful and medium amounts of easily soluble phosphorus by the Bray test when certain soils which give a marked response to phosphorus fertilization were analyzed. Very little iron was dissolved from soils by solutions less acid than pH 2.7.

"Climatic conditions are frequently interfering factors from the standpoint of determining response of soils to phosphorus fertilization as compared with the amount of easily soluble phosphorus present in the soil. Also soils which contain large amounts of organic matter may be rather low in easily soluble phosphorus, but little response is obtained from phosphorus fertilization, since enough of this element is obtained by the plant as a result of the mineralization of organic phosphorus by the bacteria and fungi in the soil."

The nature of phosphate fixation in soils, M. C. FORD (*Jour. Amer. Soc. Agron.*, 25 (1933), No. 2, pp. 134-144).—This contribution from the Wisconsin Experiment Station records experiments in which soils, and certain pure minerals believed to be present in soils, were treated with soluble phosphates and later examined to ascertain the degree and nature of the fixation.

The soils were found to fix phosphorus in varying degrees in forms not easily soluble in aqueous sulfuric acid of pH 3. Goethite (limonite) fixed phosphorus in a form largely insoluble in aqueous sulfuric acid of pH 3, while hematite did not. The phosphorus fixed by bauxite was of intermediate solubility. The dehydration of goethite through heating produced hematite. A partial dehydration of bauxite increased its fixing power. Further dehydration reduced this capacity but did not entirely destroy it. The phosphates formed with goethite and partially dehydrated bauxite were found on X-ray analysis to be crystalline.

A prolonged heating of six soils at 185° destroyed fixation in relatively insoluble forms in one soil, practically destroyed it in two others, and greatly reduced it in the remaining three. "This great reduction in fixation is believed to be due chiefly to the dehydration of goethite. The failure of prolonged heating at 260° C. to reduce fixation correspondingly in some soils is believed to be due to the increased activity of bauxite brought about by heating."

The phosphorus fixed by soils as calcium or magnesium phosphates was found readily soluble in weak solvents "and thus quite available to plants"; that which was fixed as ferric and aluminum phosphates by ferric and aluminum hydroxides, chlorides, or sulfates was at least in part easily hydrolyzable and available to plants; while that which was fixed by goethite (limonite) was found very insoluble and only slowly available to plants. "The amount of goethite present in different soils is believed to vary greatly and to persist in soils when once formed, because of insufficient heat in soils to dehydrate it."

A survey of Ohio orchard soils relative to phosphorus distribution and acidity, J. H. GOURLEY and R. M. SMOCK (*Ohio Sta. Bul.* 517 (1933), pp. 22, figs. 3).—A survey of 27 Ohio orchard soils, 12 of which are here reported upon, indicated that the available phosphorus content is low in the acid soils of eastern and southern Ohio, but relatively high in the less acid soils of the northwestern portion of the State. When phosphorus was applied to sod orchards there was little, if any, percolation of available phosphorus to a depth of more than 3 in. Cultivation effected a mechanical distribution of available phosphorus to the depth of tillage.

The low pH of many of the Ohio orchard soils is considered the primary cause of failures of leguminous, or, in extreme cases, even of nonleguminous cover crops in those sections, satisfactory cover crops or other orchard covers on such soils being grown only after adequate applications of lime.

Effect of various factors on the pH of peats, M. M. McCool (*Contrib. Boyce Thompson Inst.*, 4 (1932), No. 4, pp. 497-511).—Several factors which may alter the H-ion concentration of peats were studied. The work yielded the observations, among others, that the pH values of a reed-and-sedge peat and of sedge-reed peat changed to a small extent upon widening the peat-to-water ratio; that the values for another reed-and-sedge peat, a sedimentary peat, and a silty sedimentary peat became about 1.0 greater upon high dilution; and that the changes in the reaction of the remainder of the peats induced by dilution were slight. Thirteen peats were air- and oven-dried and their pH values, with those of the moist peats, were determined after 10 minutes and after 24 hours. The change induced was in some cases slight, in others greater. Those affected to the greatest extent were the oven-dried reed-and-sedge peat, woody sedge-and-reed peat, reed-and-hypnum peat, the air- and oven-dried sedimentary peat, and the woody peat. Air-drying increased the soluble salt content of several of the peats, and oven-drying resulted in a greater concentration of the solution of each of them. There was no correlation between the pH changes induced by drying and the soluble salt content of the peats.

The H-ion concentration of the very acid peats became markedly less upon leaching with distilled water, the less acid peats changing much less in this respect. It appeared that the fine material present in the very acid peats was largely responsible for their low pH values, since upon its removal they became much less acid.

The addition of 0.1 N Ca(NO₃)₂ increased the H-ion concentration of the peats. Less striking changes were obtained with the addition of 0.1 N solution of KCl, KNO₃, NH₄Cl, NH₄NO₃, (NH₄)₂SO₄, and NaNO₃. Monobasic sodium, potassium, and ammonium phosphate reacted in a similar manner with the less acid peats. The M solutions did not alter the pH values of the stronger acid peats and M/10 affected them but slightly. Large additions of commercial superphosphate (16 percent P₂O₅) and a 4-8-7 commercial fertilizer were required to alter the pH values of the peats. The addition of powdered sulfur to the moist peats lowered their pH values. The rate of change was more rapid in some than it was in others. The acid resulting from the addition of the sulfur was difficult to remove by leaching with water.

Studies on the biological decomposition of peat, R. M. SNYDER and Z. N. WYANT (*Michigan Sta. Tech. Bul.* 129 (1932), pp. 63, figs. 15).—For the purpose of a study of chemical and microbial changes, a mixture of peat, rock phosphate, and solid and liquid manure was composted in a pit for a year. During this time the citrate-soluble phosphorus increased over two and a half times (the available phosphorus in material which had been composting anaerobically for a year being increased by composting aerobically). Aerobic cellulose decomposition increased for several months, then gradually decreased. Anaerobic cellulose decomposition was active for the first six months, gradually decreasing thereafter in the upper layers, so that, at the end of the year, anaerobic cellulose decomposers could be isolated only from the bottom of the pit and in comparatively small numbers.

The count of *Azotobacter* decreased sharply during the first four weeks, then gradually, especially in the upper layers of the peat. The counts of *Azotobacter* did not increase when the peat was restored to aerobic conditions.

Bacteria forming nitrates from nitrites were present during the first two months of composting. Organisms producing nitrite from ammonia appeared to live longer but gradually died out, as did the organisms forming ammonia from urea. Warm weather caused renewed ammonification. Sulfate-reducing organisms persisted for some time, showing greater activity in the lower layers. Colon organisms maintained themselves for at least 8 months, being particularly active in the bottom of the pit.

The microbial changes induced in raw peat by composts were studied, with results described in part as follows: "A small amount of compost was found to be as effective as a small application of manure in bringing about changes in the peat, using the growing plant as an indicator. The use of clay and sulfur in such compost combinations appears to be without effect, although clay and sulfur when used together on peats low in fertility gave a response. The addition of manure to peat results in an increase in fertility so great that the manure cylinder yielded as much during the eighth and ninth years of continuous cropping as the unmanured cylinder which had been fallow prior to the eighth year. Raw peat treated with composts tends to maintain its fertility during the later years of long continued cropping. The incorporation of sand in peat increases the biological activity and the response of the crop. A small application of manure to peat when the peat is covered with a surface foot of sand brings about a favorable response of the crop growing on the sand. The biological activity in composts decreases with age. This activity is revived when new sources of energy-producing foods are added to the old composts."

Investigations on the microbiology of forest soils, D. FEHÉR (*Untersuchungen über die Mikrobiologie des Waldbodens. Berlin: Julius Springer, 1933, pp. VI+272, figs. 76*).—This monograph, covering the results of about 10 years of systematic investigation, takes up, in addition to some generalizations briefly dealt with in the introduction, methods of investigation, the bacteria of forest soils, the microbiological basis of the carbon dioxide respiration of forest soil, the microbiological investigation of the nitrogen cycle of forest soil, the changes in the average annual data concerning the biological transpositions in forest soils, the microbiological properties of sandy soils, the microscopic fungi of forest soils, investigations on the regional distribution of algae in European forest soils, the protozoa of forest soils (by L. Varga), and, in an appendix by R. Bokor, the microbiology of the "szik" (saline or alkaline) soils with reference especially to their restoration to fertility. An extensive classified bibliography is also appended.

Nitrogen fixation in some Michigan soils, L. M. TURK (*Michigan Sta. Quart. Bul., 15 (1933), No. 3, pp. 183-190, figs. 2*).—A study of six soil types indicated "that the soils of Michigan . . . contain a rather active nonsymbiotic nitrogen-fixing flora." Of the soils examined, Brookston loam showed the highest nitrogen-fixing capacity. Nitrogen fixation was greatly increased by the addition of fresh organic matter (especially legumes), lime, phosphorus, and potassium, either alone or in combination. The addition of alfalfa, especially when supplemented with lime in the case of strongly acid soils, greatly stimulated nitrogen fixation in the soils studied.

"Possible practical applications for the foregoing results emphasize the necessity for consideration of the nitrogen-fixing organism in a good system of soil management. The results secured also emphasize the need of a more thorough study of the importance of nonsymbiotic nitrogen fixation in field soils in Michigan."

The story of Field A of the Massachusetts Agricultural Experiment Station: A review of experiments with nitrogen fertilizers, F. W. MORSE

(*Massachusetts Sta. Bul.* 290 (1932), pp. 23, fig. 1).—The bulletin records some of the main results of 50 years' work on a field laid out on exhausted hay land in 1883 and kept under continuous plat experiment since that date.

The early corn crops indicated that this "run out" hay land contained nitrogen which had been accumulated without nitrogen fertilizers. Following four successive years of clover and grass, the plats without nitrogen fertilizers led all others in their average yields of corn and stover in 1911, and in the last year of the experiment clover hay was heaviest on these plats. Nitrogen fertilizers were most effective when a tilled crop followed a tilled crop.

Judged by crop yields, sodium nitrate was usually most effective, ammonium sulfate requiring calcium carbonate in the soil for the best effect. When recently limed, the ammonium sulfate plats were virtually equal to the sodium nitrate plats. Farm manure, supplemented with phosphate and potassium compounds, excelled several times with crops which made their growth in summer. Organic nitrogen was superior in three seasons. Other results are also recorded and analyzed.

A general conclusion drawn from the study of the voluminous data accumulated from this long period field work is, in part, that "field experiments should be planned primarily to afford the investigator an opportunity to test under practical conditions, on a small inexpensive scale, those theories, principles, and processes which have been developed under controlled conditions in the laboratory and vegetation house. To depend upon such experiments to furnish the information and data upon which practices and theories may be based and developed is not justified and is sure to prove disappointing. Where such work has been continued for a long period of years without change, it has resulted in the accumulation of a large mass of records which could not be interpreted in terms of much agronomic value. An intelligent program requires variation in the details of treatment and management in conformity with the changes in economic conditions" affecting the work.

Commercial fertilizers and soil acidity, A. W. BLAIR (*New Jersey Sta. Circ.* 266 (1933), pp. 3).—The potential acidifying effects of ammonium sulfate and of some other ammonium salts and mixtures containing them are noted, together with the proportionate quantities of calcium carbonate or of hydrated lime required to neutralize the acidity set free in the utilization of these ammonium compounds; and the relative values, from the viewpoint of the counteracting of acidity thus produced, of such fertilizer materials as calcium cyanamide, sodium nitrate, calcium nitrate, basic slag, wood ashes, rock phosphate, farm manure, etc., are briefly discussed.

Analyses of commercial fertilizers, H. E. CURTIS, H. R. ALLEN, and L. GAULT (*Kentucky Sta. Bul.* 325 (1931), pp. 477-583).—The bulletin covers, for 1931, the usual analyses and related information.

Analyses of commercial fertilizers and ground bone; analyses of agricultural lime, 1932, C. S. CATHCART (*New Jersey Sta. Bul.* 551 (1933), pp. 19).—Continuing the data largely recorded in Bulletin 549 (E.S.R., 68, p. 599), the present bulletin contains "the remaining analyses together with a discussion of the whole inspection."

Inspection of fertilizers, W. I. ADAMS and A. S. KNOWLES, JR. (*Rhode Island Sta. Ann. Fert. Circ.*, 1932, pp. 17).—Of the largest number of samples ever collected in the State, 95 percent met guaranties fully, and but 2 percent showed deficiency equaling or exceeding 0.3 percent. The number of brands offering 20 percent or more of plant food was more than double that of the previous year, and several brands carried from 40 to 50 percent.

Inspection of agricultural lime products, H. D. HASKINS (*Massachusetts Sta. Control Ser. Bul. 66* (1932), pp. 8).—In 36 liming materials the analyses recorded showed but one serious deficiency, and in the gypsum products, no deficiencies.

AGRICULTURAL BOTANY

Plant physiological chemistry, R. B. HARVEY (*New York and London: Century Co., 1930, pp. XIX+413, figs. 119*).—"It is the purpose of this text to present the physiological chemical mechanism of the vital processes of plants. Most attention will be given to the metabolic reactions, with some of the chemistry underlying the process, but complete description of the chemical compounds of plants does not lie within the province of this text. . . . Free use has been made of every source of information. . . . No great amount of new research data is presented here, but the material which has been used for illustration is of a nature such as should give a new point of view to students of plant physiology and of the plant sciences in general. The main part of the discussion is devoted to the synthesis, translocation, storage, digestion, and utilization of substances within the plant. The viewpoint is mainly physiological, but the interpretation necessarily involves chemistry and physics. It is assumed that the student has some knowledge of chemistry and physics as well as of general botany and plant physiology."

[**Plant physiology studies of the New York Cornell Station**] (*New York Cornell Sta. Rpt. 1932, pp. 111, 112*).—Data are briefly reported as to studies on the direct utilization of leucine, glycine, and aspartic acid by orchid embryos and the nonsymbiotic germination of *Calluna vulgaris*, both by L. Knudson; the catalyzing action of manganese on iron and the necessity of iron for the growth of *Lemna minor*, by E. F. Hopkins; the relation of manganese to plant growth, by A. Saeger; and the influence of X-rays on plants, by Knudson.

Absorption of water by aerial parts of plants [trans. title], N. ZAMFIRESCU (*Bul. Min. Agr. și Domen. [Rumana], 3* (1931), No. 5-6, Sup., pp. 105, figs. 49; *Fr. abs.*, pp. 101-105).—Plants can secure in part the water they require via their aerial parts, especially the leaves, the anatomical structure of which is favorable to its entrance. Absorption is considered an appropriate technical name for this process in plants.

The effect of drought on the osmotic value of plant tissues, W. A. BECK (*Protoplasma, 8* (1929), No. 1, pp. 70-126).—The effect of drought on the osmotic value at incipient plasmolysis (O_x) was studied in 14 experiments using various tissues of the leaf of *Hedera helix*. It is claimed that the data collected are so arranged that the effect of drought and the accompanying factors can readily be detected for the different tissues. The epidermal tissues were very irregular in their response, which is held to indicate that the influence of the accompanying factors easily predominates over the influence of drought. Temperature seemed particularly effective, low temperature increasing the O_x , and, within limits, high temperature decreasing it under drought conditions.

The influence of a nutritive medium previously used for *Ophiobolus miyabeanus* when afterward so used for another fungus [trans. title], S. SATOH (*Mem. Col. Agr., Kyoto Imp. Univ., No. 13* (1931), pp. 41-54, figs. 2).—In the liquid culture used for development of *O. miyabeanus* two kinds of material were formed, one of which favored and the other hindered the growth of *Aspergillus niger*. Particulars regarding these are given.

Hydrogen-ion phenomena in plants, I—III, J. I. ARMSTRONG (*Protoplasma*, 8 (1929), Nos. 2, pp. 222–260, figs. 7; 3, pp. 313–343, figs. 2; 4, pp. 508–521).—The three sections of this account respectively report on hydron concentration and buffers in the fungi, an investigation of the buffer complex of sap from stems of *Pelargonium* sp., and the acidity of certain cell walls considered in relation to the higher fatty acids.

Observations on the effect of pH value on oxidase activity, W. V. CRUESS, R. N. JEFFREY, and H. M. PANCOAST (*Amer. Jour. Bot.*, 19 (1932), No. 10, p. 841).—In this study at the University of California it was found that oxidase activity, as measured by the rate of absorption of oxygen by the expressed juices of peach, apricot, olive, apple, avocado, asparagus, and spinach, was greatly affected by pH values, the absorption of oxygen practically ceasing at values below 2.5. Above pH 4 absorption was more rapid than below this point. Citric acid and sodium hydroxide were used to modify pH.

Catalase activity and respiration in the leaves of growing barley, M. N. POPE (*Jour. Agr. Res. [U.S.]*, 46 (1933), No. 1, pp. 35–40, fig. 1).—The rate of respiration in leaves of Hauncheon barley was found to be inversely proportional to the stage of maturity. Catalase activity varied directly with the age of the leaf until full maturity, when it decreased rapidly with the decrease in the amount of living material in the tissues. Respiration rate and catalase activity in homologous younger leaves of comparable barley plants were correlated negatively, while in older leaves relationships were indefinite. The negative correlation found between respiration and catalase activity is contrary to results of others, but it is deemed probable that any correlation is fortuitous. Current methods of determination probably can measure total catalase activity only if it is a by-product of metabolism or has a function other than the breaking down of hydrogen peroxide.

Dwarf plants from unafter-ripened embryos of seeds of *Rhodotypos kerrioides*, F. FLEMION (*Amer. Jour. Bot.*, 19 (1932), No. 10, pp. 837, 838).—When excised embryos were mixed with moist peat moss at 25° C. a small percentage of seedlings were obtained, despite the absence of previous after-ripening at low temperature. The resulting plants grew very slowly, and in fact were essentially dwarfs until some 4 to 7 months later, when normal growth began.

The possibility of senility resulting from long-continued vegetative reproduction [trans. title], A. P. C. BLOUWER (*Lab. Tuinbouwplantent., Wageningen, [Meded.]* 12 (1930), pp. 119, figs. 5, Eng. abs. pp. 95–103; also in *Meded. Landbouwhoogeschool Wageningen*, 34 (1930), No. 4, pp. 119, figs. 5, Eng. abs. pp. 95–103).—In this paper senility, especially in the higher plants, is discussed.

"At present all the 'symptoms of senility' are known to be caused by infectious diseases, among which virus diseases are prominent." Both discussion and experimentation, it is claimed, have failed to solve the question as to the occurrence of senility. They have, moreover, raised new questions. Criticism is offered as to the methods reported, as also to the lack of adequate application of the mathematical method. "It is thus rendered quite open to question whether in working with clone material any attention need be paid to the theory of senility."

The formative effect of day length on wheat seedlings, A. M. HUBB-KARRER (*Jour. Md. Acad. Sci.*, 1 (1930), No. 2, pp. 115–126, figs. 5).—The experimentation herein described is claimed to have proved the importance of a short day to the initiation of the rosette growth in fall-sown winter wheat plants, and to have evidenced the relationship of this factor with temperature

and with some soil condition, supposedly moisture. This resting period, if not essential, is at least conducive to the subsequent normal growth and maturation of the wheat plants.

Cultivation of plants in artificial light [trans. title], J. W. M. ROODENBURG (*Lab. Tuinbouwplantent., Wageningen, [Meded.] 14 (1930), pp. 68, figs. 22, Eng. abs. pp. 62-66; also in Meded. Landbouwhooges. Wageningen, 34 (1930), No. 8, pp. 68, figs. 22, Eng. abs. pp. 62-66*).—In the autumn of 1928 a start was made upon a thorough study of the possibilities inherent in the cultivation of plants in artificial light. To the incandescent lamps at first used were later added the neon tube light and the mercury vapor tube light. The features, uses, and values of these are dealt with in detail, and their applicability to work with plants as supplementary to or in substitution for sunlight is discussed in connection with sweet pea seedlings, strawberries, or lilies-of-the-valley.

It is claimed that such preliminary experimentation has proved the possibility of using artificial light economically in the cultivation of plants during winter, though the most economical methods are yet to be developed. "The best source we have to our disposal is neon light so far." Practical considerations are outlined.

Shifting of the periodicity: Adaptation and export to the Southern Hemisphere (hyacinth and tulip) [trans. title], A. H. BLAAUW, I. LUYTEN, and A. M. HARTSEMA (*Lab. Plantenphysiol. Onderzoek, Wageningen, Meded. 28 (1930), pp. 105, pls. 2, figs. 8; Eng. abs., pp. 87-105*).—Since 1922 the authors have experimented with hyacinths and tulips endeavoring to shift the blooming by six months and to test in the Netherlands and later in the Southern Hemisphere the plants so dealt with. They outline their conclusions from both a botanical and a practical standpoint.

It appears that for the inhibition of buds on a plant, and thus for a shifting of its periodicity, the thing of principal significance is the point of time at which the inhibition (influenced largely by temperature) begins, consequently the state in which the buds are at that time. For hyacinth and tulip this inhibition should take place when the leaflets of the buds are as nearly as possible in the embryonic state, as the more these organs are developed the more difficult to arrest their growth and the lower the temperatures required for this purpose. This becomes evident later when after development some leaves are seen to be abnormally shorter and narrower, or even lacking entirely in development. The work, its results, and conclusions therefrom are set forth with detailed analytic discussion.

A method for determining the specificity of the intracellular globulin of *Fusarium lini*, C. I. NELSON (*Jour. Agr. Res. [U.S.], 46 (1933), No. 2, pp. 183-187*).—By using a method described in this contribution from the North Dakota Experiment Station, specific antigenic protein material may be obtained from mycelial masses of *F. lini*. A fraction corresponding to globulin possesses antigenic specificity in a higher degree than prepared mycelial masses. Globulins thus obtained from *F. lini* and purified by electrodialysis were used as antigens to produce antisera in rabbits. By a special microtechnic, the specificity of these antiglobulin sera was checked against homologous and heterologous antigens. The serological tests indicated that the globulin obtained from the mycelial masses of *F. lini* was a reactive and specific antigen.

[Fungi in relation to stored hay and corncocks] (*Iowa Sta. Rpt. 1932, p. 40*).—Data are reported by A. L. Bakke and E. R. Henson on the relation of *Rhizopus tritici* and *Aspergillus flavus* to thermogenesis in stored hay and

by J. C. Gilman on *A. flavus*, *A. terreus*, *Penicillium oxalicum*, and *R. tritici* to the decomposition of corncob meal.

Tropical and subtropical agricultural plants of the world: Their history, culture, and significance for political economy.—I, **Starch and sugar plants**, A. SPRECHER VON BERNEGG (*Tropische und Subtropische Weltwirtschaftspflanzen: Ihre Geschichte, Kultur und Volkswirtschaftliche Bedeutung.*—I. Teil, *Stärke- und Zuckerpflanzen.* Stuttgart: Ferdinand Enke, 1929, vol. 1, pp. XV+438, pls. 3, figs. 130).—This deals, in its several sections, with rice (*Oryza sativa*), maize (*Zea mays*), sorghum (*Sorghum vulgare*), manioc (*Manihot utilissima*), sweetpotato (*Ipomoea batatas*), yam (*Dioscorea* sp.), taro (*Colocasia antiquorum*), arrowroot (*Maranta arundinacea*), Indian cane (*Canna* sp.), turmeric (*Curcuma* sp.), pia or Tahiti arrowroot (*Tacca pinnatifida*), Japanese arrowroot (*Pachyrhizus angulatus*), vegetable pear or chayote (*Sechium edule*), sago palm (*Metroxylon* sp.), sugarcane (*Saccharum officinarum*), and sugar palm (*Arenga saccharifera*).

The identification of the more important prairie hay grasses of Nebraska by their vegetative characters, F. D. KEIM, G. W. BEADLE, and A. L. FROLIK (*Nebraska Sta. Res. Bul.* 65 (1932), pp. 40, figs. 36).—An analytical key, based on vegetative characters, is presented as a guide in the identification of 27 grass species contributing appreciably to the prairie hay crop of Nebraska. The key is supplemented by illustrations and descriptions of the most important characters and merits of these grasses.

GENETICS

Genetic mutations produced by electro-magnetic induction and X-rays, A. PIROVANO ([*Internatl. Rev. Agr.*], *Mo. Bul. Agr. Sci. and Pract.* [Roma], 23 (1932), No. 9, pp. 330-338, figs. 5).—Following a discussion of the principles involved and a description of the apparatus employed, the author reports the results of experiments at the Fruit Growing and Electro-genetic Institute of Roma with a constant breeding strain of *Cucurbita pepo*. The pollen used was taken from male flowers subjected to electromagnetic oscillations the evening before opening. The fruits resulting from pistillate flowers fertilized with treated pollen varied markedly in form and color, and the seeds were considerably smaller than those of normal fruits. Mutations obtained have remained constant through nine succeeding generations. Work with vinifera grapes yielded mutations remarkable for the abundance of suckers and flowers. Two of these grapes, named Galvani and Volta, were very desirable on account of earliness.

Bud mutation in horticultural plants [trans. title], V. CARRANTE (*Italia Agr.*, 69 (1932), No. 10, pp. 350-370, figs. 10).—This is a general discussion of the subject, supported by illustrations and descriptions of fruit mutations in the orange and lemon and by references to other mutations in the almond, walnut, grape, and potato.

A dominant mutation of frequent recurrence in sorghum, R. E. KARPEN (*Amer. Nat.*, 66 (1932), No. 707, pp. 511-529, fig. 1).—A dominant tall mutant, recurring frequently among a number of pure lines of Standard Blackhull kafir continuously inbred for a prolonged period at the Texas Experiment Station, was found to differ from normal by a single gene, and seemed to be the result of frequent gene mutation, likely taking place during gametogenesis of the parental plant. Economically, the new type is considered superior from the viewpoint of forage and silage, although inferior as to convenience in harvesting for grain.

The genetics of a thread-leaved tomato mutant [trans. title], E. SCHIEMANN (*Ztschr. Induktive Abstam. u. Vererbungslehre*, 63 (1932), No. 1-2, pp. 43-93, figs. 34).—Arising as a variation of the commercial variety Comet, this thread-leaved mutant was found at the Berlin-Dahlem Botanical Museum to hybridize with normal forms on a monofactorial basis. Four characteristics, namely, drooping habit, thread-shaped leaves, choripetalous blooms, and weak growth, were apparently controlled by a single factor. The number of chromosomes (12 haploid) was unchanged, and the reduction divisions progressed normally.

Mutant types of the dwarf banana, E. E. CHEESMAN (*Trop. Agr. [Trinidad]*, 10 (1933), No. 1, pp. 4, 5, figs. 2).—Instances of presumable sporting in the ordinary dwarf banana are cited in support of the hypothesis that varieties such as the Congo, with naked rachises, were derived from *Musa cavendishii*.

Xenia and metaxenia in apples, II, B. R. NEBEL and I. J. TRUMP (*Natl. Acad. Sci. Proc.*, 18 (1932), No. 5, pp. 356-359).—In this second contribution (E.S.R., 64, p. 819) from the New York State Experiment Station, the authors report that McIntosh apples fertilized, respectively, with Red Astrachan and Yellow Bellflower pollen differed essentially. Where Red Astrachan was used as the pollen parent the fruits were significantly heavier, the pH values were significantly lower and less variable, and seed length was significantly less. Determinations of acidity by titration also showed that apples of Red Astrachan parentage were the more acid. In outward appearance the Red Astrachan group was obviously superior.

Linkage relations of a second brown midrib gene (bm_2) in maize, C. R. BURNHAM and R. A. BRINK (*Jour. Amer. Soc. Agron.*, 24 (1932), No. 12, pp. 960-963, fig. 1).—A second brown midrib character (bm_2), genetically distinct from although resembling the brown midrib (bm_1) described by Eyster (E.S.R., 56, p. 328) and Jorgenson (E.S.R., 66, p. 727), was found to be inherited as a simple recessive in studies by the Wisconsin Experiment Station and the California Institute of Technology. The gene appeared to be located in the *P-br* group, the probable order of the factors tested being *P-br-f-an-gs-bm_1*. Its location in this chromosome at a point remote from *P* and *f* greatly extended the map of the group.

The effect of a lethal in the heterozygous condition on barley development, D. W. ROBERTSON (*Colorado Sta. Tech. Bul.* 1 (1932), pp. 12, fig. 1).—Single lethals studied in four barley varieties included the white seedling factor Single lethals studied in four barley varieties included the white seedling factor pairs A_1a_1 in Colless and A_4a_4 in Hanna, a yellow seedling factor pair X_1x_1 in Black Hull-less, and the white seedling factor pair $A_{12}a_{12}$ in Canada Thorpe, which also affected the endosperm. Comparison of measurements of the homozygous green plants with those of the heterozygous plants revealed no significant differences in number of culms per plant, average length of culm, average length of head, number of grains per plant, and total weight of grain per plant. When the lethal seedling factor pair was associated with an endosperm deficiency, there was a significant difference in total grain weight per plant. The results indicated that there is no detrimental effect of a single seedling lethal factor in the heterozygous condition in the development of the barley plant.

The inheritance of characters in ragi, Eleusina coracana (Gaertn.).—**Part VI, Earhead shapes**, G. N. R. AYYANGAR, P. K. RAO, and U. A. WARIAR (*Indian Jour. Agr. Sci.*, 2 (1932), No. 3, pp. 254-265, pls. 3).—Panicle shape in ragi, according to the sixth contribution in this series (E.S.R., 67, p. 25), may be grouped broadly as curved, in which the digitate spikes of the inflorescence curve in, and opens, in which they are open. A factor for density *Q*, responsible for a close assembly of spikelets on the rachis, is present in the curved and

absent in the opens. Curveds may be separated further into in-curveds, of which the spikes curve in, and top-curveds, longer than the in-curveds, in which only the tops curve. A second factor *E* determines the elongation of the rachis and separates the top-curveds and the in-curveds. *E* is also present in the opens, and its presence or absence gives rise to the groups long-opens and short-opens, which are separated with difficulty, although they could easily be demonstrated from segregates with top-curveds and in-curveds, respectively. *Q* and *E* are independent of factors for plant purple pigmentation.

Inheritance of dwarfing in wheat, D. C. TINGEX (*Jour. Agr. Res.* [U.S.], 46 (1933), No. 1, pp. 74-94, figs. 10).—A genetic study of dwarfing in wheat (E.S.R., 67, p. 663) secured from 15 crosses and from observations on the occurrence of dwarfing in 77 others is reported on from the Utah Experiment Station. Results obtained on the studies of the F_2 and F_3 generations of tall \times tall, tall \times dwarf, and intervarietal crosses were explained on a two-factor basis, i. e., a dominant dwarfing factor *DD* and an inhibiting factor *II*. Besides the two genetic types, *DDII* and *ddii*, there were varieties of the *ddII* type. A tentative genetic classification in respect to dwarfing is presented for varieties and strains used in the crosses.

Some observations on the characters of wild rice hybrids, S. K. MITRA and P. M. GANGULI (*Indian Jour. Agr. Sci.*, 2 (1932), No. 3, pp. 271-279, pl. 1).—In a cross between Latisail, a cultivated rice, and wild rice (*Oryza sativa fatua*), the F_2 resembled the wild parent yet showed marked heterosis. The color of the leaf sheath, pulvinus, ligule, leaf margin, and internode of the apiculus and stigma, and of the node, and the spreading v. erect growth habit were monofactorial in inheritance, while two complementary factors appeared to be involved in the color of auricle, of outer and inner (floral) glumes, of inner (mature) glumes, and of kernel, and panicle habit, and awn length. See also an earlier note on color inheritance in rice (E.S.R., 59, p. 219).

Pollen abortion in species hybrids, D. KOSTOFF (*Cytologia*, 3 (1932), No. 4, pp. 337-339, figs. 4).—The abortion of a high percentage of the pollen in *Secale* spp. hybrids, involving *S. cecale* and *S. montanum*, and also in *Nicotiana* spp. hybrids, appeared due to the retardation of the meiotic processes and the nuclear division in the pollen, whether or not the pollen had a complete haploid set of chromosomes. Such retardation of the meiotic processes seemed to be due to abnormal biophysical and biochemical processes created by the hybridization, e. g., the increase of the cytoplasmic viscosity in certain *Nicotiana* spp. hybrids.

Some results of inbreeding grade Guernsey and grade Holstein-Friesian cattle, T. E. WOODWARD and R. R. GRAVES (*U.S. Dept. Agr., Tech. Bul.* 339 (1933), pp. 32, pls. 6).—Grade dairy cows were mated with Guernsey and Holstein bulls and the daughters mated back to their sire in the test with Guernseys. This was repeated for successive generations in the experiment with Holsteins, using sons and grandsons of the original sire.

After making suitable corrections for live weights and milk and butterfat production to bring the data to a comparable basis, it was found that the inbreeding reduced birth weights and mature weights of both Guernseys and Holsteins. Inbreeding also lowered the vigor of the calves as measured by the mortality after birth and rate of growth.

The number of services required for conception and the number of abortions were unchanged in successive generations of inbreeding in the Holstein herd, but it was necessary to close out the study with the Guernseys after two generations on account of an outbreak of infectious abortion.

The milk and butterfat production was increased and the fat percentage lowered as the concentration of Holstein blood increased.

A recessive lethal factor appeared when the Guernsey sire was mated to his daughters.

Twinning, sex ratios, and genetic variability in birth weight in sheep, A. B. CHAPMAN and J. L. LUSH (*Jour. Heredity*, 23 (1932), No. 11, pp. 473-478).—In the grade Hampshire flock of the Iowa Experiment Station there were 1,019 lambs born from 1915 to 1930, of which 722 were twins. The proportion of the sexes was 48.4 percent of males to 51.6 percent of females. A study was also made of the variance in the birth weights of the twin lambs grouped according to sex, litter, and year of birth, from which it is concluded that no more than from 25 to 30 percent of the variance in birth weight was genetic, about 30 to 35 percent was caused by tangible environment, and about 40 to 45 percent arose from intangible environment or accidents of development, including intrauterine competition.

Nine independently inherited autosomal factors in the domestic fowl, D. C. WARREN (*Genetics*, 18 (1933), No. 1, pp. 68-81, fig. 1).—The results are given of studies at the Kansas Experiment Station of matings between domestic fowls exhibiting nine autosomal characters, of which the dominant members of the allelomorphic pairs were naked neck, rumpless, white skin, leg-feathering, rose comb, pea comb, crest, polydactyly, and dominant white. The lack of linkage relations may be observed in the following table, which gives the numbers produced in back-crosses of double heterozygous parents to double recessives:

Offspring produced in back-cross tests for linkage, the first number being the non-cross-overs and the second the cross-overs

Factor	Dominant white	Polydactyly	Crest	Pea comb	Rose comb	Leg-feathering	White skin	Rumpless
Naked neck.....	304-308	187-239	125-107	664-721	348-374	656-679	398-430	890-827
Rumpless.....	194-193	199-181	112-122	165-186	353-369	280-292	250-236	-----
White skin.....	161-148	112-110	107-115	120-123	163-155	217-248	-----	-----
Leg-feathering.....	157-137	199-182	115-119	727-697	325-310	-----	-----	-----
Rose comb.....	194-183	148-146	80-92	388-506	-----	-----	-----	-----
Pea comb.....	285-262	152-160	177-173	-----	-----	-----	-----	-----
Crest.....	-----	121-113	-----	-----	-----	-----	-----	-----
Polydactyly.....	161-149	-----	-----	-----	-----	-----	-----	-----

¹ From a paper by A. S. Serebrovskii and S. G. Petrov. Zhur. Eksper. Biol. (*Jour. Biol. Expt.*), 6 (1930), No. 3, pp. 157-180.

Flightless—A heritable variation in the domestic fowl, D. C. WARREN (*Jour. Heredity*, 23 (1932), No. 11, pp. 449-452, figs. 3).—A study of the inheritance of the flightless character in fowls, in which the large feathers of the wings and tail break off, is reported from the Kansas Experiment Station. In matings of a male showing this characteristic with normal females 129 flightless and 136 normals were produced, indicating that the character is dominant and the flightless male is heterozygous. Other matings of the flightless daughters confirmed this hypothesis. There were no indications of sex differences or interference with the viability of flightless birds.

Genetics of the fowl.—II, A four-gene autosomal linkage group, F. B. HURR (*Genetics*, 18 (1933), No. 1, pp. 82-94).—Continuing this series at the Minnesota Experiment Station (E.S.R., 63, p. 818), back-cross matings of double heterozygous frizzled dominant white birds to the double recessives showed about 18 percent crossing over. There were 157 offspring produced in the repulsion phase and 168 in the coupling phase. With the establishment of linkage between the frizzling and dominant white genes it follows that the

four genes for dominant white, frizzling, crest, and cerebral hernia are located in the same chromosome. The suggested order is dominant white 10 cross-over units from cerebral hernia, which is separated by 8 units from frizzling, with crest 28 units distant and nearer the opposite end of the chromosome. The genes for rose comb and white shanks were not located in this group as they were inherited independently of frizzling and dominant white. Fourteen autosomal characters not located with the dominant white, frizzling, crest, and cerebral hernia group are listed, together with evidence of their independent inheritance.

The relation of sex to crossing over in the fowl is also discussed.

Factors affecting the breeding of the field mouse (*Microtus agrestis*).—I. Light, J. R. BAKER, and R. M. RANSON (*Roy. Soc. [London], Proc., Ser. B*, 110 (1932), No. B 767, pp. 313-322, fig. 1).—In studying the influence of light on reproduction in the field mouse, it was found that by reducing the daily exposure to electric light from 15 to 9 hours the number of pregnancies was reduced from 24 for an average of 7.5 control females to 4 for an average of 7.8 females exposed to 9 hours of light daily. Studies of the genital organs of the males indicated that they were fertile, but that the females were more likely to be affected by reduced light.

Occurrence of polydactyly and its mode of inheritance in the domestic guinea pig [trans. title], A. PICTER (*Ztschr. Induktive Abstam. u. Vererbungslehre*, 63 (1932), No. 1-2, pp. 1-42, figs. 5).—In matings of normal individuals from a polydactylous line there were produced 135 normals and 9 individuals showing various grades of polydactyly, a ratio of 15:1. The ratios obtained by continued breeding through eight generations led to a setting up of a 3-factor hypothesis to explain the inheritance of polydactyly. The polydactylous animals were homozygous dominants for the conditional factor *P* and heterozygous for the intensity factors *E* and *N*, each of which was contributed by different normal parents. Differences in the degree of completeness of formation of the extra digit seemed to be related to the intensity factors, but polydactyly was independent of sex and was not lethal.

The genetic basis of alkaptonuria, L. HOGGEN, R. L. WORRALL, and I. ZIEVE (*Roy. Soc. Edinb. Proc.*, 52 (1931-32), No. 3, pp. 264-295, pls. 6).—The authors state that an analysis of the cases of alkaptonuria reported in the literature indicates that the disease is hereditary and due to a recessive autosomal gene, although a dominant type was also observed.

Studies in human inheritance.—VI, A genetic refutation of the principles of "behavioristic" psychology, D. C. RIFE and L. H. SNYDER (*Human Biol.*, 3 (1931), No. 4, pp. 547-559, figs. 8).—In continuing this series (*E.S.R.*, 66, p. 523) a study was made of the pedigrees of inmates of various institutions showing special ability. It is pointed out that special musical, mechanical, mathematical, and artistic ability may develop even in the presence of feeble-mindedness. This indicates that training and instruction which frequently fail to bring out special ability do not play a very important part in expression of special ability.

A genetical formula for the inheritance of intelligence in man, C. C. HURST (*Roy. Soc. [London], Proc., Ser. B*, 112 (1932), No. B 775, pp. 80-97).—The inheritance of intelligence in man is suggested as being due to the operation of a major gene *N* for normal intelligence and five modifying genes, based on a study of the intelligence of 388 parents and 812 offspring in Leicestershire families and 424 parents and 558 offspring in royal families of the principal European countries.

Filial and fraternal correlations in sex-linked inheritance, L. HOGGEN (*Roy. Soc. Edinb. Proc.*, 52 (1931-32), No. 3, pp. 331-336).—The theoretical cor-

relations between parent and offspring and brothers and sisters with and without dominance of autosomal and sex-linked characters are presented as follows:

Filial and fraternal correlation coefficients for autosomal and sex-linked characters

Relationship	Dominance complete		Heterozygote intermediate	
	Autosomal	Sex-linked	Autosomal	Sex-linked
Father-son.....	0.33	0.00	0.50	0.00
Mother-daughter.....	.33	.33	.50	.50
Father-daughter.....	.33	.58	.50	.71
Mother-son.....	.33	.58	.50	.71
Brother-brother.....	.42	.50	.50	.50
Brother-sister.....	.42	.29	.50	.35
Sister-sister.....	.42	.67	.50	.75

The correlation of relatives on the supposition of sex-linked transmission, L. HOGGEN (*Jour. Genetics*, 26 (1932), No. 3, pp. 417-432).—In addition to the correlations noted above, the theoretical avuncular, grandparental, and cousin correlations in case of sex-linked inheritance are presented. The high correlation of 0.375 for male pairs of maternal first cousins seems most significant for detecting the contribution of sex-linked genes.

Self-sterility and cross-sterility in plants and animals, F. BRIEGER (*Selbststerilität und Kreuzungssterilität im Pflanzenreich und Tierreich. Berlin: Julius Springer, 1930, pp. XI+395, figs. 118*).—This volume deals in systematic and analytic detail with parasterility in higher plants, parasterility in Metazoa, and parasterility in Thallophyta and Protista, with a concluding section considering adaptation and sexuality. An extensive literature list and a name and subject index complete the small but compact volume.

The physiological and genetical aspects of sterility in domesticated animals, W. ORR and F. F. DARLING (*Edinburgh: Imp. Bur. Anim. Genet., 1932, pp. 80*).—Various pathological conditions responsible for sterility are described as well as nutritional influences on normal reproduction. Under the relation of genetic factors to sterility there are discussed hereditary abnormalities of the reproductive system and lethal factors. An extensive bibliography, by M. V. Cytovich, is included.

The gonadotropic hormones (ρ -factors), I, II (*Quart. Jour. Expt. Physiol.*, 21 (1931), No. 2, pp. 147-179, fig. 1; 21 (1932), No. 4, pp. 315-318).—Two parts are here presented.

I. *The preparation and properties of extracts of anterior lobe, placenta, and pregnancy urine*, B. P. Wiesner and P. G. Marshall.—The results are reported of tests of the potency of extracts of the anterior lobe of ox pituitary, human placenta, and pregnancy urine in inducing ovulation in immature mice. Several methods were found for preparing active extracts of the anterior lobe of the pituitary and the placenta, but phosphotungstic acid and alcohol precipitation were most successful for purifying the prolactin from pregnancy urine. Large doses of prolactin inhibited oestrus, while small doses induced ovulation. The possibility of two factors being present in prolactin is discussed.

II. *Selective filtration experiments*, P. G. Marshall.—An attempt was made to get some indication of the molecular size of the gonadotropic hormones of the anterior lobe of the hypophysis and the placenta by passage of extracts

through different sized filters. Extracts free of protein were found reduced in potency when passed through the filters in which the pores were $3\ \mu$ or less in diameter. The molecular weight between that of Congo red and benzo-purpurin, about 800-900, was suggested for the p -factors.

Further studies on estrin-hypophyseal antagonism in the white rat, J. SPENCER, F. E. D'AMOUR, and R. G. GUSTAVSON (*Endocrinology*, 16 (1932), No. 6, pp. 647-654, figs. 4).—In studying the possibility of overcoming the inhibitory effect on growth of continued oestrin injections, 3 lots of 20 3- to 4-weeks-old rats each received daily injections as follows: (1) Ten rat units of oestrin, (2) the same amount of oestrin and an extract of pregnancy urine, (3) the same amount of oestrin and the growth hormone of the hypophysis, with a fourth lot of controls receiving no injections. Pregnancy urine had no influence on the growth of the oestrin-injected animals. The growth of those receiving oestrin and the growth hormone of the hypophysis was increased practically equal to the controls, but the growth of the long bones was not as great. The extract of pregnancy urine improved the weight and development of the gonads in oestrin-injected rats. The inhibition of growth and gonadal development as a result of long-continued oestrin administration seemed to be due to an inhibition of the hypophysis.

The influence of oestrin on the gonad-stimulating complex of the anterior pituitary of castrated male and female rats, R. K. MEYER, S. L. LEONARD, F. L. HISAW, and S. J. MARTIN (*Endocrinology*, 16 (1932), No. 6, pp. 655-665).—As the ovaries of immature rats receiving implants of hypophyses from castrated male and female rats previously injected with oestrin weighed, respectively, 45 and 47 percent less than the ovaries of immature rats receiving implants of hypophyses from noninjected castrated males and females, it is concluded that oestrin decreases the amount of gonad-stimulating complex in the hypophyses of castrated male and female rats.

Studies on the hypophysectomised ferret, I-III, M. HILL and A. S. PARKES (*Roy. Soc. [London], Proc., Ser. B*, 112 (1932), No. B 775, pp. 138-158, pls. 3, figs. 4).—Three papers in this series are reported.

I. *Technique* (pp. 138-145).—The first paper describes the operation for the removal of the hypophysis in the ferret.

II. *Spermatogenesis* (pp. 146-152).—The influence of the hypophysis on spermatogenesis was determined by studying the testes following hypophysectomy in five ferrets. After 30 days the weight of the testes was reduced to less than half, and the epididymis was reduced as compared with the normal. The spermatid tubules showed progressive atrophy, and primary spermatocytes were the last stage of spermatogenesis detectable. Although the epididymis assumed the quiescent state of anoestrus a few spermatozoa were present in the epididymis 30 days after the removal of the hypophysis.

III. *Effect of post-coitus hypophysectomy on ovulation and the development of the corpus luteum* (pp. 153-158).—Removal of the hypophysis 1 hour 50 minutes or longer after the beginning of coitus, which was as soon as the operation could be performed, did not prevent ovulation in five female ferrets. None of the animals showed any signs of pregnancy at autopsy performed up to 28 days after copulation, and corpora lutea did not develop normally. It appears that the ovulation-producing hormone is secreted into the circulation in less than 2 hours after copulation.

Modification of mammalian sexual cycles; reactions of ferrets (*Putorius vulgaris*) of both sexes to electric light added after dark in November and December, T. H. BISSENETTE (*Roy. Soc. [London], Proc., Ser. B*, 110 (1932), No. B 767, pp. 322-336, pl. 1).—Three female ferrets came in heat and copu-

lated between October 12 and January 5, which is in the normal anoestrous period. This abnormal condition was in response to exposure from 6 to 6.5 hours of additional electric light each day. Spermatogenesis and other indications of the breeding season were also stimulated in males, but no mature sperms were produced even with 71 days of the light treatment. The results are based on observations of the males and females and their behavior, and microscopical studies of the testes of the males.

The reproductive processes of certain mammals.—III, The reproductive cycle of the male ferret, M. ALLANSON (*Roy. Soc. [London], Proc., Ser. B, 110 (1932), No. B 767, pp. 295-312, pls. 3, figs. 7*).—Continuing this series (*E.S.R.*, 67, p. 121) observations are reported on the weights and character of the testis, epididymis, vas deferens, and penis of 16 adult and 3 immature ferrets, killed at different times of the year. These organs showed much greater development during the active breeding season from March to July than at the more or less quiescent period during the balance of the year. The greater development in these organs is correlated with an increased diameter of the seminiferous and epididymal tubules, an increase in the height of the epithelium lining of the tubules, and an increase in the amount of fat in the interstitial cells of the testis. The testis varied from 0.016 percent of the body weight in the quiescent period to 0.219 percent in April.

Spontaneous activity in male rats in relation to testis hormone, R. E. HELLER (*Endocrinology, 16 (1932), No. 6, pp. 626-632*).—From studies of the voluntary activity of normal male and castrated rats, before and after administration of extracts of the testis hormone, it was apparent that voluntary activity was not a good measure of the testis hormone as the amount of activity was very irregular, although less average activity was shown by castrated animals.

An improved fluid for mammalian sperm-suspensions, J. R. BAKER (*Quart. Jour. Expt. Physiol., 21 (1931), No. 2, pp. 139, 140*).—A buffered glucose-saline solution which promotes the activity of mammalian spermatozoa is suggested. The results of tests of several modifications in the solution are noted.

The effect of destruction of the spermatogenic tissue by X-rays upon certain secondary gonadic characters of the cock, L. MIRSKAIA and F. A. E. CREW (*Quart. Jour. Expt. Physiol., 21 (1931), No. 2, pp. 135-138, pls. 3*).—The germinal tissue of the testes of four cocks was destroyed by X-rays without resulting influence on the head furnishings, voice, or behavior, indicating that these secondary sex characters are not dependent for maintenance on the spermatogenic tissue.

The spermatogenesis of the mouse (*Mus musculus*, var. *albula*), P. R. CUTRIGHT (*Jour. Morph. and Physiol., 54 (1932), No. 1, pp. 197-220, pls. 4*).—Spermatogenesis in the mouse is described from studies of sections of the testes of animals of varying ages. Young animals 6 to 8 weeks old, however, gave the best results. The diploid chromosome number of 40 was verified in the spermatogonia and in the embryonic somatic tissue. The probable X and Y chromosomes were also identified. Other details of the process are described and illustrated.

A case of intersexuality in *Bos indicus*, with a theory of the significance of the genetic male intersex, D. R. R. BURT (*Roy. Soc. Edinb. Proc., 50 (1929-30), No. 2, pp. 113-129, pls. 2*).—The gross anatomy and histology of the genitalia of a zebu exhibiting both male and female characteristics is described.

The effects of alcohol on the germ cells of male rabbits, R. B. HINMAN and H. J. MERZGEM (*New York Cornell Sta. Rpt. 1932, p. 109*) —Alcoholization

of male rabbits increased the percentage of abnormal young and the rate of resorption of young sired by them.

Mammary development and function, S. A. ASDELL and L. L. MADSEN (*New York Cornell Sta. Rpt. 1932*, pp. 105, 106).—A brief account is given of a successful attempt for a short time to stimulate milk secretion in goats by administration of an extract of the anterior lobe of the hypophysis.

Menstruation in *Pithecus* (*Macacus*) *rhesus* following bilateral and unilateral ovariectomy performed early in the cycle, G. VAN WAGENEN and S. B. D. ABERLE (*Amer. Jour. Physiol.*, 99 (1931), No. 1, pp. 271-278, figs. 6).—Bilateral ovariectomy performed at different stages in the cycle, varying from 72 hours to 13 days, was followed in 5 or 6 days by menstruation in 4 macaques, but did not induce bleeding when the ovaries were removed on the first day on which menstruation was noted. Unilateral ovariectomy in two animals on the fourth day induced menses in one and not in the other.

FIELD CROPS

The principles of orthogonality and confounding in replicated experiments, F. YATES (*Jour. Agr. Sci. [England]*, 23 (1933), No. 1, pp. 108-145, figs. 7).—"Orthogonality is that property of the design which insures that the different classes of effects to which the experimental material is subject shall be capable of direct and separate estimation without any entanglement." The principle of orthogonality in replicated experiments is discussed, the dangers of nonorthogonality emphasized, and modifications needed in ordinary procedure of analysis of variance when applied to nonorthogonal data are developed, with attention to the shorter methods. Certain modifications in the design of replicated experiments, usually designated by the term confounding, are explained, and the different types of confounding and their uses are discussed, with appropriate methods of analysis. The methods are applied to the analysis of the experiment on sugar beet by Wishart (*E.S.R.*, 67, p. 672) and a potato experiment by Eden and Fisher (*E.S.R.*, 63, p. 731).

On the validity of Fisher's z test when applied to an actual example of non-normal data, T. EDEN and F. YATES (*Jour. Agr. Sci. [England]*, 23 (1933), No. 1, pp. 6-17, figs. 5).—A practical test was made on a skew distribution obtained from the observation of 256 height measurements on wheat grown at Rothamsted, and the distribution of values of R. A. Fisher's z from 1,000 random samples was obtained and found to agree satisfactorily with the theoretical distribution. The results indicated that the z test might safely be applied to data of this type. Previous work on the validity of the t and z tests on nonnormal distributions is reviewed.

[Field crops experiments at the Alaska Stations, 1931 and 1932], C. COMDY, J. C. WINGFIELD, and F. L. HIGGINS (*Alaska Stat. Rpt. 1931-1932*, pp. 3, 4, 5, 6, 11, 12-14, 17, 18, 19, 22, 23, 24).—Experiments (*E.S.R.*, 66, p. 626) reported on for 1931 and 1932 included variety trials with spring wheat, barley, oats, flax, potatoes, beets, turnips, carrots, alfalfa, sweetclover, and grasses for lawns, and cover crops; time of digging potato varieties; trials of oats and peas for silage, and oats and vetch for hay; comparison of cutting oats and vetch hay with a binder and with a mower; and weed control. Analyses are tabulated for cotton sedge (*Eriophorum vaginatum*), native blue top grass (*Calamagrostis* sp.), and native sedge (*Carex aquatilis*) harvested at different growth stages, and bird vetch, alfalfa, and brome grass harvested in full bloom, all grown at Fairbanks in 1929. The accomplishments of the station in introducing and developing suitable varieties of cereals, potatoes, and storage roots, grasses, and legumes are reviewed briefly.

[**Agronomic experiments in California**] (*California Sta. Rpt. 1932, pp. 49-51, 66, 67, 68*).—These pages report the progress results (E.S.R., 67, p. 516) of breeding work with Sudan grass, grain sorghum, and rice; variety tests with flax; oats and legume mixtures for hay; cutting tests with alfalfa; burning to control weeds and aphids in alfalfa; fertilizer tests with rice and corn; benefits of cover crops on milo, cotton, and cantaloupes; effects of plowing under straw on the succeeding grain crop; effects of sorghum residues on physical condition of the soil; weed control by use of arsenicals, chlorates, and other chemicals; studies on St. Johnswort (E.S.R., 64, p. 737) and on the feed value of Pahrute weed (*Suaeda depressa*); and experiments on the merits of burning alfalfa and grazing lands. Some of the work was in cooperation with the U.S. Department of Agriculture.

[**Agronomic research in Delaware**], G. L. SCHUSTER, H. C. HARRIS, and C. E. PHILLIPS (*Delaware Sta. Bul. 179 (1932), pp. 11-18*).—Field crops experiments (E.S.R., 66, p. 526) reported on briefly included a variety trial with alfalfa; a date-of-seeding test with barley; fertilizer studies with wheat, alfalfa, barley, and sweetpotatoes; and a storage test with sweetpotatoes from the several fertilizer treatments.

[**Field crops work at the Georgia Coastal Plain Station, 1931**] (*Georgia Coastal Plain Sta. Bul. 19 (1932), pp. 11-57, 66-72, 88-93, figs. 6*).—Agronomic experiments (E.S.R., 66, p. 626) reviewed for the current season and for various periods comprised variety tests with cotton, corn, oats, wheat, rye, barley, peanuts, lespedeza, soybeans, and cowpeas for hay and seed, winter field peas, vetch, Crotalaria, sweetpotatoes, and tobacco; a source of seed test with potatoes; breeding work with corn; fertilizer trials with cotton, corn, oats, peanuts, velvetbeans, sweetpotatoes, potatoes, and tobacco; effect of lime, green manure, and superphosphate on oats; winter cover crops for cotton and corn; cultural (including planting) experiments with oats, wheat, cotton, soybeans, winter field peas, vetch, sweetpotatoes, potatoes, and tobacco; pasture studies; and a study of color inheritance in sweetpotatoes. Certain lines of research were in cooperation with the Georgia College of Agriculture, the Georgia Experiment Station, and the U.S. Department of Agriculture.

[**Field crops experiments in Indiana**] (*Indiana Sta. Rpt. 1932, pp. 19-21, 28, 29, 47, 58, 59, 63, 64, 65, figs. 4*).—Research with field crops (E.S.R., 67, pp. 516, 667), reviewed briefly, included breeding work with wheat, oats, soybeans, and red clover; adaptation studies with new oats varieties, strains of red clover, and varieties of lespedeza; comparison of Indiana-grown v. imported seed potatoes; cutting tests with alfalfa; a fertilizer test with tobacco; trials of nitrogenous fertilizer for corn as a possible aid in control of European corn borer; studies of the effects of fertilizers and of leaf rust on the yield, composition, and quality of wheat; fertilized crop rotations; place in the rotation to apply manure; soil fertility studies; pasture improvement; and weed control with chlorates and other chemicals.

[**Farm crops experiments in Iowa**] (*Iowa Sta. Rpt. 1932, pp. 40, 41, 42, 45, 46, 60-73, 89, 90, 105, 106, 107, fig. 1*).—Brief reports are given on the progress (E.S.R., 67, p. 377) of work by R. H. Porter, C. M. King, A. L. Bakke, J. M. Aikman, F. G. Bell, C. S. Reddy, L. C. Burnett, H. D. Hughes, F. S. Wilkins, P. E. Brown, F. B. Smith, J. B. Wentz, C. Y. Cannon, M. T. Jenkins, A. A. Bryan, J. L. Robinson, W. G. Gaessler, R. W. Jugenheimer, H. Giese, E. W. Lindstrom, and A. T. Erwin, including breeding work with oats, barley, wheat, reed canary grass, potatoes, and soybeans; variety tests with oats, flax, alfalfa, red clover (strains), soybeans, and sorgho; trials of legumes and grasses for hay and pasture; variety-cultural experiments with oats, wheat, and barley; cultural studies with reed canary grass and sugar beets, and with alfalfa on

bacterial wilt infected soil; the relation of moisture to respiration in stored oats; technic for determining water content of green forage; trials of nurse crops for small-seeded legumes; trials of legumes for green manure; storage and fertilizer tests with sweetpotatoes; tests of agricultural seed for purity and germination; studies of the annual spread of and control methods for creeping Jennie and leafy spurge; and eradication of biennial sweetclover by cultivation.

Corn investigations dealt with genetic interrelations and prepotencies of inbred lines; the relation of time of planting to yield and quality of produce among crosses between inbred lines; comparison of inbred lines obtained from open-pollinated varieties and from crosses between inbred lines; improvement through the use of inbred lines; the relation between the development and seed value of the corn kernel; ear and kernel characteristics of seed corn in relation to yield; the measurement of limiting environmental factors in the growth of the plant at different rates and spacings; correlation between composition and stiffness of stalk; rate, date, and method of planting varieties differing in maturity; a study of varieties and strains in different parts of Iowa; a statistical study of the relation of size and shape of plot and number of replications to precision in yield comparisons; and storage studies. Certain phases of the research were in cooperation with the U.S. Department of Agriculture.

[**Field crops and plant breeding research in New York**] (*New York Cornell Sta. Rpt. 1932*, pp. 91, 113, 130, 131, 162, 163).—These pages give brief accounts of the progress of breeding work with corn, wheat, oats, barley, beans, and potatoes; of potato experiments concerned with adaptation of types and varieties to muck soil and new and improved strains; of the effect of liberal nitrogenous fertilization on yields and nitrogen content of timothy hay; and of tests of grass mixtures for pasturage.

[**Field crops investigations in Ohio**] (*Ohio Sta. Bul. 516 (1933)*, pp. 22-29, 30, 31, 33, 34, 35, 36, 42, 43, 63, 64, 67, 107, 111, 112, fig. 1).—Agronomic experimentation (E.S.R., 67, p. 29), for which results are reported, dealt with drilling light applications of lime with clover seed, by R. M. Salter; the fertility value of hay crops in the rotation, by E. E. Barnes; sodium chlorate-limestone mixtures as weed killers for dry application, by C. J. Willard; effect of fertilizers on seedling stands of sugar beets, by J. S. Cutler and J. B. McLaughlin; alfalfa and grass mixtures v. pure stands, by L. M. Thatcher; the value of the coarser particles in ground limestone, by Salter; cultipacking and mulching wheat, by H. L. Borst; comparisons among corn hybrids and varieties, by G. H. Stringfield; the effect of fertilizers upon grain texture and protein content of wheat, by E. G. Bayfield; control of crabgrass by shading, by F. A. Welton; the effects of plot arrangement upon experimental error, by J. T. McClure; the form of potassium in corn tissues, by V. H. Morris; the variability of certain characters in corn, by J. D. Sayre; control of Canada thistle and horse nettle with sodium chlorate sprays, by H. A. Runnels; fertilizer placement studies with potatoes, by J. Bushnell; spacing, spraying, and overhead irrigation tests with potatoes, by D. Comin and Bushnell; trial of the clover-alfalfa-timothy mixture on meadows, by M. A. Bachtell and H. Allen; sugar beet yields in different rotations and on different preparations, by Bachtell and H. R. Hoyt; and steaming of tobacco plant beds and use of corn stalks to loosen plant bed soil, both by Cutler and H. M. Wachter.

Several of the investigations were in cooperation with the U.S. Department of Agriculture.

[**Field crops work in Puerto Rico, 1932**], T. B. McCLELLAND, R. L. DAVIS, and H. C. HENRICKSEN (*Puerto Rico Sta. Rpt. 1932*, pp. 2, 6-8, 11-16, 19,

figs. 2).—Brief progress reports are given as heretofore (E.S.R., 67, p. 517) on breeding work, trials of seedlings, hybrids, and introduced varieties, studies of arrowing of varieties, and determination of the rate of movement of lithium in the plant, all with sugarcane; breeding work with corn and yams; fertilizer trials with dasheens, taros, and yautias; and tests of corn varieties and hybrids.

The corn and soybean combination, H. L. BORST and J. B. PARK (*Ohio Sta. Bmo. Bul.*, 18 (1933), No. 2, pp. 37-42).—This study of growing corn in combination with soybeans for silage or grain has been noted (E.S.R., 68, p. 610).

Manuring of meadow-hay land: The effect of manures and lime on the botanical composition and yield of hay, W. A. JACQUES (*Jour. Agr. Sci. [England]*, 23 (1933), No. 1, pp. 146-160, *figs. 2*).—An experiment begun by the late W. Somerville at Leeds University Farm, Garforth, in 1899 and in progress up to 1927 dealt with the effects of manure, fertilizer, and lime on yield and botanical composition of meadow hay. The soil is a light loam derived from a coal measures sandstone, naturally sour, and produces a poor type of herbage typical of a large area.

During the first period, 1899-1911, manure each year and manure alternating with complete or incomplete fertilizer with sodium nitrate gave the highest yields. All the manured plats yielded better than any of the fertilized plats, on which there was a progressive decrease in productivity with the omission of potash and then superphosphate from the complete mixture. Sodium nitrate in all cases produced heavier yields than ammonium sulfate. In the second period, 1912-27, the unlimed half-plats occupied about the same position in average production as in the first period. The manured plats still maintained their superiority over fertilized plats and the sodium nitrate outyielded the ammonium sulfate plats, yet the average level of production was more than 0.5 ton less than in the first period, indicating that the continual removal of hay from the same land each year, even in conjunction with heavy and complete fertilizing, depresses yield. The limed half-plats, excepting two which were manured, outyielded the corresponding unlimed halves. The increase was greatest on controls and on plats receiving fertilizers only, and was least with manure alone or when supplemented with fertilizers.

In regard to the herbage, continuous applications of ammonium sulfate, with or without lime, induced no improvement as compared with the controls, although the yield was somewhat greater. Sodium nitrate brought about an improvement over ammonium sulfate by reducing bent and sweet vernal and increasing the orchard grass. Complete fertilizer proved better than incomplete fertilizer, although kainit had little effect on the floral composition. Manure without lime encouraged orchard grass and rough-stalked meadow grass, but depressed tall oatgrass. Where manure was used annually the proportion of undesirable plants in the hay was less than on any other plat. Manure and lime tended to suppress bent and Yorkshire fog. Manure gave a better hay than complete fertilizers, as with the latter sheep's and hard fescues, sweet vernal, and bentgrass replaced orchard grass, which became abundant with manure. The effect of lime on the individual species varied with the manuring. The behavior of the plants in response or otherwise to lime and manures often agreed closely with Rothamsted findings by Brechley (E.S.R., 54, p. 435).

Alfalfa production under irrigation in western Texas, J. J. BAYLES (*Texas Sta. Bul.* 472 (1932), pp. 28, *figs. 10*).—Production and irrigation practices for growing alfalfa for hay under irrigation in western Texas are described, with information on the climatic, soil, and fertility needs of the crop, its place in rotations, the seed crop, varieties, pasturing alfalfa, and the control of

weeds and insect pests. Fertilizer trials with alfalfa and a study of the effect of fallow on the control of cotton root rot (*Phymatotrichum omnivorum*) in alfalfa fields, both conducted at the Balmorhea Substation, are reviewed briefly.

Another yield trial with Pusa barleys: The method of analysis of variance, R. D. BOSE (*Agr. and Livestock in India*, 2 (1932), No. 6, pp. 603-618).—Yield trials with four Pusa barleys, conducted in randomized blocks and Latin squares and the data analyzed by Fisher's analysis of variance method, proved the superiority of Type 21 over Types 12, 20, and 7 in order, confirming earlier results in trials employing the chessboard method and the strip and block methods.

Red-clover seed production in the Intermountain States, E. A. HOLLOWELL (*U.S. Dept. Agr. Leaflet 93* (1932), pp. 7, figs. 2).—Cultural methods and field practices are suggested for the production of red clover seed in the Intermountain States.

Some effects of high temperature on polyploidy and other variations in maize, L. F. RANDOLPH (*Natl. Acad. Sci. Proc.*, 18 (1932), No. 3, pp. 222-229; *abs. in New York Cornell Sta. Rpt.* 1932, p. 113).—Heat (38° to 45° C.) was applied locally to the ear shoots of corn for two days beginning 27-30 and 22-24 hours after pollination. The ear-shoot region of the plant was inclosed within a wire mesh cylinder plugged at the ends with cotton and surrounded by an electrical heating pad. Effects of the heat treatments noted included (1) doubling of entire chromosome sets; (2) chromosomal deficiencies and translocations; (3) direct morphological effects resulting in defective and scarred endosperms, germless grains, and dwarfed and otherwise defective seedlings and mature plants; (4) sterilization of ovules and pollen at the higher temperatures; and (5) deviations from the normal fertilization process, such as failure of syngamy, atypical syngamic unions, and parthenogenesis. The higher temperatures were more effective than the lower in producing tetraploids and aberrant kernel types.

In a study of the effects upon the fertilization process of heat treatments applied separately and in combination with X-radiation at the time of syngamy, the following variations were noted: A new type of endosperm chimera not previously reported in corn, a diploid glossy seedling produced from a colored starchy grain, a maternal diploid seedling, and a maternal haploid. Possible applications of the technic are suggested.

Chemical transformations of phosphorus in the growing corn plant, with results on two first-generation crosses, E. E. DETURK, J. R. HOLBERT, and B. W. HOWK (*Jour. Agr. Res. [U.S.]*, 46 (1933), No. 2, pp. 121-141, figs. 5).—A preliminary study of the distribution of various chemical forms of phosphorus in the corn plant at different stages of its development, and the distribution of the total phosphorus among four groups of compounds, organic and inorganic, in two F₁ crosses is reported by the Illinois Experiment Station cooperating with the U.S. Department of Agriculture.

In field-grown open pollinated corn plants a gradual decrease in percentage concentration of phosphorus during rapid vegetative growth was observed, and a sudden drop in concentration in the vegetative portion took place at about pollination. During the early ear-formation stage there was an upward gradient in total phosphorus concentration from the roots through the stalk and shank to the ear. Phytin was consistently absent from all parts of the plant before pollination, and after pollination it occurred only in developing or mature seeds. A relation of the phytin-forming function to fertilization is indicated, and the pollen is suggested as the carrier of the activator of the phytin-synthesizing enzyme. Phytin disappeared rapidly from germinating corn seeds.

In two F_1 crosses which varied greatly in their response to phosphate fertilizers, phosphorus was separated into four fractions at each of five growth stages, extending from 36 days before until 11 days after pollination. Two fractions, inorganic and organic phosphorus compounds soluble in cold aqueous 2 percent HCl, were labile and readily retransported from older tissue into ears, and possibly into younger vegetative tissues. These compounds are believed to be primarily transport and storage forms and not essential constituents of protoplasm. The remaining fractions, i.e., phospholipids (absolute alcohol extract) and acid-insoluble organic phosphorus compounds (nucleic acids and nucleoproteins) remained constant in percentage of the dry matter throughout the experiment, and are believed to be constituents of the cell protoplasm and not subject to reutilization, with the possible exception of a breakdown of small amounts of phospholipids. Chemical differences in the two F_1 crosses did not reveal causes of the differences in response to phosphate fertilizers.

The effect of fertilizers, crop rotation, and weather conditions on the anchorage of corn plants. N. A. PETTINGER (*Virginia Sta. Tech. Bul. 46 (1933), pp. 36, figs. 8*).—The effect of different plant nutrients, crop rotation, and weather conditions on the root development and anchorage of corn plants, as determined by the resistance of the plants to vertical pull, and the percentage of plants leaning 20° or more, were studied from 1927 to 1932.

Application of nitrogenous fertilizers to a soil slightly deficient in nitrogen increased the anchorage of corn plants slightly when the available potassium was adequate, but when this was not ample, addition of nitrogenous fertilizers decreased the anchorage to a small extent. In a soil deficient in available phosphorus, application of phosphatic fertilizers markedly increased the anchorage, superphosphate being far superior to rock phosphate in this respect. Stable manure alone was slightly more effective than stable manure supplemented with either rock phosphate or superphosphate in providing the plants with good anchorage. Potassic fertilizers (E.S.R., 60, p. 19) also greatly improved the anchorage of plants in a soil low in available potassium. Under the experimental conditions potassium and phosphorus in order increased root anchorage more than did nitrogen, the relative stimulative effects being about inversely proportional to the extent in which each element was deficient in the soil in available form. The percentage of leaning plants and the resistance to vertical pull both showed a high positive correlation with soil productiveness, indicating that fertile soils are more favorable to root growth than unproductive soils. Root anchorage was correlated positively with the degree of completeness of fertilization.

Crop rotation was found to be more favorable to good root development and anchorage of corn plants than was the growing of corn continuously. Weather conditions appeared to exert a stronger influence than fertilizers or cropping system in determining the amount of lodging. The amount and distribution of rainfall evidently has more influence than wind velocity. Lodging is encouraged by excessive rainfall but not by subnormal rainfall. The concentration of rainfall during August seemed to encourage lodging more than the concentration at other times in the growing season. Wind velocity increased lodging when rainfall was abundant, but was ineffective with subnormal rainfall. The simultaneous occurrence of rainfall and fast-moving winds appeared to be more effective than either factor alone in producing lodging in corn.

On the variation of certain characters of cotton in relation to the position of seeds in a lock. K. R. SEN (*Indian Jour. Agr. Sci., 2 (1932), No. 5, pp. 484-498, figs. 2*).—Studies on well-opened bolls of the Punjab-American cottons known as Early Strain, 4 F, and 289 F, showed that the seed weight

and lint weight are correlated. The apical seeds gave the lowest seed and lint weights, although the seed and lint weights of the basal seeds were also low. Experiments with the Early Strain only indicated that the apical seeds give fibers of the least weight per unit length, the lowest ginning percentage, and the fewest hairs per seed, whereas the fiber weight per unit length and the ginning percentage are highest for the basal seeds. The average fiber length did not seem to vary with the seed positions. The results are in accord with Turner's conclusions (E.S.R., 63, p. 827) as to the absence of correlation between the numbers of hairs per seed and either the ginning percentage or the seed weight. A statistical note on the analysis of variance, by S. S. Iyer, is appended.

Physiological factors affecting the fruiting of cotton with special reference to boll shedding, R. S. HAWKINS, R. L. MATLOCK, and C. HOBART (*Arizona Sta. Tech. Bul.* 46 (1933), pp. 361-407, pls. 3, figs. 30).—Anatomical and physiological aspects of the cotton plant, studied in relation to environmental conditions and with particular reference to soil-moisture relations, included fruiting behavior—flowering, shedding of bolls, and maturity of bolls; osmotic values and specific conductivity of the expressed leaf fluids; carbohydrate and nitrogen relations; and certain anatomical differences determined from cross sections of the stems of representative plants. The studies were made on Acala cotton grown in field plats variously irrigated.

The osmotic pressure and specific conductivity of the leaf sap and the carbohydrate content of the stems usually were correlated inversely with the available soil moisture. The amount of available soil moisture, through its influence on food conditions within the plants, appeared to be a major factor in regulating the fruiting behavior of cotton plants. Relatively high osmotic pressures of the leaf sap almost invariably were followed by low percentages of shedding of the bolls, the flowers of which opened simultaneously with the occurrence of high osmotic pressures. High shedding also followed extremely high osmotic pressures induced by severe reductions in soil moisture, and increased shedding practically always followed low osmotic pressures. Curves representing the specific conductivity of the leaf sap paralleled the osmotic-pressure curves with exceptional consistency, and the percentages of carbohydrates in the stems were correlated fairly closely with the osmotic pressures of the leaf sap. The interrelation of osmotic pressure and specific conductivity of the leaf sap, and the carbohydrate content of the stems, and the close inverse correlation of these three properties with shedding were held to furnish additional evidence that the percentage of shedding is regulated by the amount of plant food available for the development of the young bolls.

Cambial activity was directly correlated with available soil moisture. Rapid vegetative growth, as expressed in the formation of large, thin-walled cells in the secondary tissues of the stems, was accompanied generally by increased boll shedding, probably due to the lack of plant food for vegetative and fruiting requirements. Very slow vegetative growth, induced by lack of soil moisture following a period of normal growth, was accompanied by relatively inactive cambium, the formation of small cells, the thickening of the cell walls of the young cells, increased carbohydrate content of the stems, lower nitrogen content, and intense shedding. The total amount of pith and of cortical tissues did not change materially from July 14 to October 1, irrespective of soil-moisture conditions. The area of xylem in cross sections of the stems of plants well supplied with water considerably exceeded that in plants with limited soil moisture. The expansion in the amount of phloem also was stimulated by increased soil moisture, although to a lesser extent than was the xylem. Resumption of increased vegetative growth, as indicated by accelerated cambial activity following the termination of periods of water deficit of varying in-

tensities, was of about equal proportions irrespective of the state of cambial activity during such periods.

Periods of water shortage, initiated after the flowering season was well started, reduced the length of the flowering period in proportion to the intensity of the water deficit. The first bolls opened on all plats at about the same date, August 18 and 19, irrespective of soil moisture differences.

Fertilizer experiments with cotton, E. B. REYNOLDS, G. T. MCNESS, R. A. HALL, P. R. JOHNSON, R. H. STANSEL, H. DUNLAVY, P. B. DUNKLE, and H. F. MORRIS (*Texas Sta. Bul.* 469 (1932), pp. 31).—In fertilizer experiments with cotton reported on from the station and several substations for different periods from 1925 to 1931, inclusive, the various treatments were based on a 4-12-4 mixture at the acre rate of 400 lb. Previous fertilizer work with cotton in Texas is reviewed.

The sandy soils in eastern Texas, i.e., the Kirvin fine sandy loam at Troup and Nacogdoches and Ruston fine sandy loam at Nacogdoches were found to be deficient in nitrogen and phosphoric acid, and to a lesser extent in potash. The application of 200 to 400 lb. per acre of a 4-8-4 or a 4-6-4 fertilizer, or a mixture furnishing similar ratios and amounts of plant food is recommended for cotton on these soils. That Lake Charles clay, an extensive soil in the Gulf Coast Prairie, is markedly deficient in phosphoric acid, was indicated by results obtained at Angleton. The use of 100 lb. of superphosphate or from 200 to 600 lb. of a 4-8-0 fertilizer per acre was recommended for cotton on this clay and similar soils of the region. The Lufkin fine sandy loam at College Station responded better to phosphoric acid and potash than to nitrogen. The 4-12-4 and 0-12-4 fertilizers at the acre rate of 400 lb. were the most profitable treatments on this soil. Although cotton responded somewhat to fertilizers on the dark colored Goliad fine sandy clay loam at Beeville, Houston black clay and Houston clay at Temple, and San Saba clay at Denton, in general the use of fertilizers was not profitable on these soils.

Conference on cotton growing problems, August 1930—Report and summary of proceedings (London: Empire Cotton Growing Corp., 1930, pp. 166, figs. 10).—The proceedings of the conference of British Empire cotton workers held in August 1930, at Shirley Institute, Manchester, are reported. Papers presented, with discussion, included General Problems in the Investigation of Cotton Quality, by F. T. Peirce (pp. 9-13); Immaturity of Cotton, by G. G. Clegg (pp. 13-17); The Causes of Nep in Cotton, and the Possibilities of Its Prevention, with Special Reference to the Sudan, by M. A. Bailey (pp. 17-39); "New Place Effect" on Cotton, by J. B. Hutchinson (pp. 40-51); Uniformity of Cotton, Variation in Length, Hair Weight, etc., by C. Underwood (pp. 74-88); Methods of Correlating the Strength of Cotton Yarn with Hair Properties, by G. A. R. Foster and J. Gregory (pp. 88-95); Field Experiments and the Analysis of Yield Variation in Cotton, by E. J. Maskell (pp. 96-111); The Inter-relation of Factors in Determining the Growth of the Cotton Crop in the Sudan, by F. G. Gregory, F. Crowther, and A. R. Lambert (pp. 112-129); Black-Arm or Angular Leaf Spot Disease of Cotton Plants, by R. H. Stoughton (pp. 130-144); Note on Erosion and Soil Alkali, by A. F. Joseph (pp. 144-152); and Grafting and Graft-Hybrids in Connection with Cotton Plants, by F. E. Weiss (pp. 158-163).

Approved practices for peanut growers, B. F. FULTON, P. H. KIME, S. G. LEHMAN, and H. B. MANN (*North Carolina Sta. Bul.* 281 (1933), pp. 6).—Practices recommended for peanut production in North Carolina, based on results of experiments and the experience of successful growers, deal with the choice of varieties and soils, the use of lime, fertilizers and gypsum, cultural and

harvesting methods, care of seed, rotations, and the control of plant diseases and insect pests.

Effect of reduced oxygen pressure on rice germination, J. W. JONES (*Jour. Amer. Soc. Agron.*, 25 (1933), No. 1, pp. 69-81, fig. 1).—Germination studies with rice were made during several seasons by the U.S. Department of Agriculture cooperating with the California Experiment Station.

Rice sown in the field on the soil surface and 0.5 in. and 1 in. deep, and then submerged continuously, averaged 78.14, 20, and 2.66 percent of seedlings, respectively. No seedlings were obtained from seed sown 1.5 to 2.5 in. deep and submerged continuously, either in the field or in pots in the greenhouse, except when oxygen was forced into the soil. All seed sown on the soil surface either germinated and produced normal seedlings or failed to germinate. Of the seed sown 0.5 in. deep in the field, an average of 25.78 percent produced plumules only. With increase in depth of seeding, however, the percentage of seed producing only plumules decreased, and the percentage of seed failing to germinate increased materially. Indications are that when continuously submerged, a 0.5-in. layer of Stockton clay adobe soil materially reduced the oxygen pressure, and a layer 1 in. or deeper so reduced the oxygen pressure that normal germination did not occur. Oxygen sufficient to initiate growth of the radicle seemed to be lacking under such conditions. Seeding in the water (surface seeding in these experiments) appeared to be the best practice when rice is grown by continuous submergence.

Germinations in pots into which oxygen was forced, especially in sand, gave indications that a deficiency of oxygen probably is the main factor inhibiting normal germination in rice seed sown at various depths and continuously submerged. The development of the radicle is initiated by a suitable supply of oxygen.

Early seeding is deemed preferable to late seeding because air and water temperatures are lower early than later in the spring, and more oxygen is dissolved in cool than in warm water. The dissolved oxygen at the lower temperatures results in a larger percentage of seedlings than can be obtained at higher temperatures.

Flowering, pollination, and natural crossing in rice, W. POGGENDORFF (*Agr. Gaz. N.S. Wales*, 43 (1932), No. 12, pp. 898-904).—Observations during five years of improvement work with rice at Yanco, New South Wales, are compared with similar records in other rice-growing countries. The minimum temperature at which flowering occurred at Yanco was 72° F., relative humidity 62 percent, and maximum flowering occurred at 85° to 90° with humidity 55 to 70 percent. The highest temperature at which flowering was observed was 102°, humidity 60 percent. The same response was made to a given set of conditions by all varieties studied. Time of flowering varied with weather conditions, usually commencing at 8:30 a.m., reaching a maximum between 11:30 a.m. and 12:30 p.m., and ceasing about 3:30 p.m. The extremes observed in flowering time were 6 a.m. and 5:30 p.m. Wind, clouds, and rain affected flowering adversely. Relative humidity was the most important factor governing the amount of flowering between 72° and 100°.

The three types of pollination are described. The glumes opened to a maximum angle of about 30° in from 1 to 3 minutes and remained open for 13 to 75 minutes, the time apparently being governed by relative humidity. Cleistogamy was not observed. Pollination appeared more likely to occur after rather than at opening of the florets in long-glumed varieties. Natural crossing was observed and might be attributed to several causes.

Autogamous Turkestan rye, B. M. BENSIN (*Bul. Torrey Bot. Club*, 60 (1933), No. 3, pp. 155-160, figs. 3).—A new species of rye (*Secale turkestanicum*)

found in cultivation in 1912 in Syr Darya Government differs from ordinary rye in invariable development of three flowers instead of two in each spikelet; frequent maturity of the fruit of the uppermost flower; complete enclosure of the flower in the lemma and palea, and consequent self-pollination instead of an open flower with cross-pollination; firm attachment of the kernels and consequent nonshattering upon maturity instead of easily shattering kernels; stronger development of villous hairs at the base of each spikelet; and dark, almost black, color of the kernels. It is assumed to be a more primitive species than *S. cereale*, and it seems better adapted to a wild state and more resistant to drought.

New varieties of grain and forage sorghums, H. H. FINNELL (*Oklahoma Panhandle Sta., Panhandle Bul.* 47 (1933), pp. 8).—The yields of grain and total forage made by new sorghum varieties grown for 1 to 6 years in 3.5- and 7-ft. rows are tabulated in comparison with yields of the established varieties Dwarf Yellow milo, Dawn kafir, and Sunrise kafir. Beaver milo, Double milo, and Heilman milo (6 years) and Club kafir (4 years) were the only new sorts yielding more grain than Dwarf Yellow milo. Kansas Orange, the only new sorghum to yield more forage than Sunrise kafir during 4 years, produced only half as much grain as the latter. The origins of new varieties, not noted previously (*E.S.R.*, 64, p. 336), are described.

Sudan grass culture, L. E. THATCHER (*Ohio Sta. Bimo. Bul.*, 18 (1933), No. 2, pp. 32-34).—Practical information is given on the soil, fertilizer, and cultural needs of Sudan grass, with observations on its reaction to hot dry weather, utilization of the crop, and Sudan grass-soybean mixtures.

Fertilizer requirements of sugar cane on Yazoo very fine sandy loam in Louisiana, A. M. O'NEAL, L. A. HURST, and S. J. BREAUX, JR. (*Jour. Amer. Soc. Agron.*, 24 (1932), No. 11, pp. 888-898, figs. 9).—Fertilizer tests according to the triangle system, made on several outlying fields in Louisiana, showed that the best yields of sugarcane and sugar usually were made with combinations high in nitrogen, the 12 percent nitrogen line showing consistently high returns. The effects of different fertilizer constituents on the growth of the cane were quite evident, e.g., P.O.J. 213 from a 12-4-4 plat was comparatively straight while that from the nitrogen plat (20-0-0) was crooked. Increase in the length of millable cane was in direct proportion to the amount of nitrogen up to the 12 percent combination, beyond which there was practically no improvement. The 12-4-4 mixture evidently produced the most satisfactory cane, showing an average length of 5.75 ft. of millable stalk.

The comparative effect of muriate and sulfate of potash on the composition and quality of White Burley tobacco, P. E. KARRAKER (*Kentucky Sta. Bul.* 334 (1932), pp. 341-356).—White Burley tobacco was grown for 6 years, 1924-29, on small plats fertilized with varying amounts of potassium sulfate and chloride. The effects of the treatments were determined on the appearance, feel, and chlorine and sulfur content of the tobacco, and in 2 years on its smoking qualities. In 1927 and 1928 tobacco was grown on larger areas and sold to a tobacco company so that the effects of the treatments on quality could be determined after the regular redrying, aging, and factory processes.

Some variation existed in the effects of the treatments in different years. In all years the addition of chlorine fertilizers increased the chlorine content of the tobacco. In most years no apparent injurious effect was noted on the tobacco from applications of 50 or 100 lb. of potassium chloride per acre. However, in 1927 a slightly injurious effect was observed from a 100-lb.-per-acre application. In another year no injurious effect was observed from a 200-lb.-per-acre application, although this quantity usually injured the tobacco to a considerable extent. Rates of 400 and 800 lb. per acre were quite injurious to

the appearance and other qualities of the tobacco. The potassium sulfate treatments affected the percentage of sulfur in the tobacco to a small extent, but had little or no effect on the appearance and feel.

The burning tests on the tobacco grown on the small plats in 1927 and 1928 showed that no detrimental effect resulted from the 50- and 100-lb. applications of potassium chloride. The 200-lb. applications of this material injured the burning qualities appreciably, and the 400- and 800-lb. rates to a marked extent. Some injury to burning qualities also resulted from applications of 400 and 800 lb. per acre of potassium sulfate. On the basis of these experiments and on similar soils no injurious effect on White Burley tobacco would be expected from application of 25 lb. per acre of chlorine in fertilizers, and in general no injurious effect of consequence would be expected from applications up to 50 lb.

Hard grain texture of wheat in mechanical mixtures and in crosses, W. E. BRYAN and E. H. PRESSLEY (*Jour. Amer. Soc. Agron.*, 25 (1933), No. 1, pp. 64-69).—A partial report is given of Arizona Experiment Station studies made to ascertain to what extent hard grain texture is permanent in certain pure lines of wheats grown under irrigation. The grain yield and constancy of the hard texture of certain hard strains of Baart have been discussed earlier (E.S.R., 61, p. 639).

To test the possibility that the apparent progressive softening of certain hard-grain varieties might be due to admixtures of high-yielding soft strains as suggested by Freeman (E.S.R., 40, p. 142), three mixtures of hard Baart strain No. 34-14-17 and soft Baart No. 34-16, made up on the basis of kernel count, i.e., 25 percent hard and 75 soft, 50 hard and 50 soft, and 75 hard and 25 soft, were grown in comparison with the pure races during six years. There usually was a steady decline in the percentage of hard grains in all three mixtures, the changes over the period indicating that the average yield per plant in number of grains of the soft strain exceeded that of the hard strain. When grown separately in comparable spacings and when variations in stand were considered, the soft strain produced more heads per plant with close spacing than the hard strain, and this excess increased proportionately as the space per plant was increased. The difference in tillering or number of heads per plant seemed to account largely for the gain of the soft strain in mixtures with the hard.

When a hard Baart strain was crossed with a very soft pure line of Sonora wheat, the texture of F_1 kernels seemed as soft as self-fertilized Sonora kernels. Other crosses showed that hard Baart flowers pollinated with Sonora pollen produce kernels as hard as those produced by self-pollinated hard Baart flowers. Xenia did not seem to affect the expression of texture in these crosses. Definite segregation for texture clearly occurred in F_2 , although the number of factors involved was not so evident. It appeared probable that a single main factor separates the two types of texture, and that numerous modifying factors, also present, obscure the three expected classes in the heterozygote where dominance is absent.

Eight years' work by the Montana Grain Inspection Laboratory, July 1, 1923, to June 30, 1931, C. MCKEE, W. O. WHITCOMB, W. D. HAY, and D. M. FEESE (*Montana Sta. Bul.* 270 (1933), pp. 52, figs. 8).—The activities of the laboratory (E.S.R., 48, p. 735) in testing wheat for protein, grain grading, seed testing, and seed inspection, and in research in these lines and in milling and baking are summarized for the period indicated. Research in the laboratory has largely been noted from other publications (E.S.R., 64, p. 216; 68, p. 753).

During the period 1925-30, more than 19,000 protein tests were made. The high protein year for spring wheat was 1930 and for winter wheat 1925, while both types were low in protein in 1927. The highest protein test for spring

wheat was 20.5 percent, and the lowest 8.2. The average protein content of hard red spring wheat in each year exceeded that of hard red winter wheat, the advantage varying from 0.98 percent in 1928 to 1.81 in 1930. Protein testing is still considered important from the viewpoint of milling and baking. Moisture content of wheat at the time of test had an important influence on protein percentage, i.e., the higher the protein content of the wheat the greater was the influence of moisture content, and as the moisture content decreased the protein percentage increased, and vice versa. Special features to be considered in protein testing are listed.

During the 8 years, a total of 14,703 grades was established. The percentage of Montana wheat grading no. 1 during the crop years 1923-30 ranged from 34.8 for hard winter wheat in 1930 to 87.2 for northern spring in 1928. Some wheats graded below no. 1 due to low test weight per bushel, excessive moisture, damaged kernels, and a few other causes. The test weight ranged from 50 to 67 lb. per bushel, although most wheat came within the range 59 to 62 lb. Dockage averaged below 1 percent in from 51 to 85 percent of the wheat graded during the period. Broken wheat kernels made up 38 percent of the dockage removed in grading from 200 lots of Montana wheat in 1920. The importance of smut dockage in wheat was shown by the fact that the percentage of ear inspections of Montana wheat that graded smutty during the past 8 years ranged from 13.6 to 31.8. This percentage has been increasing. The percentage of wheat that graded mixed ranged from 2.4 in 1928 to 7.9 in 1923. About 60 percent of such wheat consisted of hard red spring and hard red winter, and the next combination was durum and hard red spring. Moisture content is considered a grading factor when it exceeds 14 percent, but it may lower premiums even when it exceeds 12 percent. Experiences of farmers with the wet wheat crop of 1925 showed that threshed wet wheat dries slowly or not at all on farms during freezing weather, and that artificial drying was expensive and unsatisfactory.

The number of samples of agricultural seed received for purity and germination tests ranged from 4,212 in 1923 to 5,589 in 1930. The purity of Montana alfalfa seed averaged 95 percent or more during the period, and the average germination by years ranged from 55 to 69 percent with 23 to 31 percent of hard seeds. Attention is called to the menace of dodder in seed, particularly in alfalfa.

HORTICULTURE

[**Horticulture at the Alaska Stations**], H. W. ALBERTS, C. CORDY, J. C. WINGFIELD, and F. L. HIGGINS (*Alaska Stas. Rpt. 1931-1932*, pp. 4, 5, 9-11, 12, 14-16, 18, *figs. 3*).—Following a brief review of the work accomplished by the stations since their beginning in the introduction of hardy fruits, vegetables, and flowers, there are presented the results of 1931 cultural tests of fruits, vegetables, and flowers, and fertilizer tests with grapevines and lawngrasses at the Sitka and Matanuska Stations.

[**Horticulture at the California Station**] (*California Sta. Rpt. 1932*, pp. 31-33, 37, 38, 39-46, *fig. 1*).—Discussions are presented upon the results of studies on the pollination of almonds, sweet cherries, apples, pears, and plums; abnormal sweet cherry blossoms and fruits; split pit and gumming of peaches; the movement of mineral plant foods in prune trees; application of superphosphate to apples and peaches; fertilizers and rootstocks for citrus; means of avoiding wind injury to citrus and persimmons; spacing of fig trees; picking frequency in relation to moldy walnuts; pruning, thinning, and girdling of grapes; rootstocks for grapes and grape varieties and breeding; genetics studies

with Crepis; and the improvement of truck crops, particularly tomatoes, carrots, lettuce, asparagus, and watermelons.

[**Horticulture at the Delaware Station**], L. R. DETJEN, L. H. STEUBINGER, C. A. McCUE, and F. S. LAGASSÉ (*Delaware Sta. Bul. 179 (1932), pp. 38-43*).—Further information (E.S.R., 66, p. 533) is presented on the progress of studies of the nature and causes of the dropping of young apple and peach fruits; premature flower stalk formation in cabbage as related to the position of the parent seed branch on the mother plant; the relative effect on peaches of nitrogen derived from different fertilizer sources; and the normal variations in apple trees growing on seedling and on own roots.

[**Horticulture at the Georgia Coastal Plain Station**] (*Georgia Coastal Plain Sta. Bul. 19 (1932), pp. 57-62, 63-65, 72-88, 100-104*).—Results are presented for varietal, cultural, and fertilizer trials with tomatoes, watermelons, and lima beans; varietal tests of asparagus, beans, peas, peppers, and other truck crops; varietal tests of apples, peaches, plums, pecans, pears, grapes, strawberries, figs, blueberries, blackberries, tung-oil trees, etc.; and cover crop trials with pecans and adaptation and selection trials with blueberries. In addition, the work at Darien involving fertilizer tests with tomatoes, beans, cabbage, and onions and variety tests with vegetables, fruits, and flowering bulbs is briefly discussed.

[**Horticulture at the Indiana Station**] (*Indiana Sta. Rpt. 1932, pp. 45-47, 48, 49, 54, 55, 57, 64, figs. 3*).—Among studies briefly reviewed are those in orchard soil management; apple pruning; apple stocks: stationary v. portable spray plants; codling moth control; apple storage; cost of washing apples; blooming time of plum varieties; resistance of asters to wilt; peat moss as a substitute for manure in the greenhouse; seed selection in tomatoes; effect of heating on color pigment of processed tomatoes; the marketing of Indiana tomatoes; the use of electric lights in the greenhouse; the effect of cultural treatments on growth and fruiting in the apple; effect of phosphorus and nitrogen deficiency in the amylase and invertase activity of tomato plants; effect of storage in alcohol on the sugar content of plant materials; methods for determining carbohydrates in plants; quantity of arsenic residue on apples; and the relation of stage of maturity and varieties to the canning quality of pumpkins.

[**Horticulture at the Iowa Station**], L. M. WEETMAN, E. C. VOLZ, T. J. MANEY, B. S. PICKETT, H. H. PLAGGE, H. L. LANTZ, V. T. STOUTEMYER, H. GIESE, E. S. HABER, A. T. ERWIN, P. M. NELSON, and P. SWANSON (*Iowa Sta. Rpt. 1932, pp. 41, 42, 96, 97, 98-104, 105, 106, 107, figs. 2*).—Reports are presented on the results of studies on the morphology and cytology of wilt-resistant types of melons; the storage of gladiolus corms; the breeding of improved varieties of chrysanthemums; methods of propagating own rooted apples; the growing of uniform rootstocks for apples; the correlation of bound water and hardness in apple wood; the comparative merits of various grafting waxes; the development of desirable new stocks for apples; soil management of apple orchards; methods of grafting to prevent formation of callus; the relation of storage temperatures to the keeping of apples; the effect of nitrogen fertilizers on the composition and keeping quality of apples; apple, pear, plum, and peach breeding; apple variety tests; grape pruning; the hybridization of black raspberries; the propagation of difficult and unusual plants; storage houses for apples; sweet corn breeding; asparagus culture; the pectin changes in stored tomatoes; cucurbit breeding; the vitamin A content of plants as associated with supplied nutrients; and substitute crops for cabbage and melon-sick soils.

[**Horticulture at the Ohio Station**], A. LAURIE, J. S. SHOEMAKER, J. H. GOURLEY, [R. M.] SMOCK, I. P. LEWIS, C. W. ELLENWOOD, F. H. BAILOU, H. D.

BROWN, O. N. RILEY, I. C. HOFFMAN, D. COMIN, S. C. HARTMAN, W. MAHAN, M. A. BACHTELL, and L. W. SHERMAN (*Ohio Sta. Bul. 516 (1933)*), pp. 55-63, 65, 66, 107, 108, 109, fig. 1).—In accordance with the usual procedure (E.S.R., 67, p. 35), brief reports are presented on the progress of various studies, such as the growth of flowering plants under cloth; the effect of supplementing the daylight period with electric lights on the time of bloom of flowers; the treatment of cuttings with emulsified paraffin and liquid rubber and various methods of handling; the nutrient needs of shade trees and flowers; the protection of evergreen stock with paraffin; the fertilizer requirements of red and black raspberries; varieties of strawberries and sweet cherries; the development of apple roots as related to culture and soil types; the value of cyanamide as an orchard fertilizer; fertilizer requirements of apple trees; the age of maximum productivity in apples; the Turley apple; the spraying and dusting of apple orchards; grafting materials and methods; varieties of vegetables; the effect of soil moisture on the yield of greenhouse tomatoes; the irrigation of muck crops; and onion varieties.

In addition there are summarized the results of orchard dusting experiments at the Washington County Experiment Farm, nitrogen fertilizer studies with apples at the Belmont County Experiment Farm, and the effect of limestone on orchard vegetation at the Mahoning County Experiment Farm.

[**Horticulture at the Puerto Rico Station**], T. B. MCCLELLAND, R. L. DAVIS, and H. C. HENRICKSEN (*Puerto Rico Sta. Rpt. 1932*, pp. 4-6, 16, 17, 18, 19, 20, 21, figs. 3).—Brief mention is made of experiments on the shading of coffee; the vegetative propagation of coffee; breeding and improvement of sweet corn; absorption of ash constituents by citrus trees; control of time of blooming of citrus trees and pineapples; and on the production of bay oil. The accession of seedlings and new forms of pineapple for future breeding work is mentioned.

The response of greenhouse crops to electric light supplementing daylight, L. GREENE, R. B. WITHROW, and M. W. RICHMAN (*Indiana Sta. Bul. 366 (1932)*, pp. 20, figs. 12).—That many ornamental plants flower earlier and more profusely when supplied with supplemental illumination was indicated in studies extending over a 2-year period and involving many species. High intensity illumination was not found essential or even beneficial with most plants; in fact the light from 50- and 100-w lamps placed 50 in. above the bench produced almost as favorable results as did much higher intensities. A relatively long period of low intensity illumination was found much more favorable in the production of earlier and more abundant flowering than were higher intensities for shorter periods. The time of night during which the additional light was supplied was often a factor but not to an extent requiring the use of specific treatments. Ultraviolet light in wave lengths shorter than those of the solar spectrum was found harmful to plants.

The variable results obtained with different species indicated that the most favorable conditions of lighting should be determined for each species and in many cases for each variety. For example, some plants illuminated only during the early seedling stage flowered as soon as others illuminated during their entire life. On the other hand, certain plants responded most favorably to illumination applied at a more mature stage.

Supplemental light made possible the production of an early spring crop of asters. Pansies and calendulas responded very favorably when illuminated with a 100-w lamp for 10 hours each night during the entire life of the plants. Easter lily (*Lilium giganteum*) flowered earliest when irradiated for the first

20 days after appearing above the soil with a 500-w lamp for 5 hours each night.

Carbon dioxide storage, III, IV, N. C. THORNTON (*Amer. Jour. Bot.*, 19 (1932), No. 10, pp. 843, 844).—Two studies are reported from the Boyce Thompson Institute for Plant Research.

III. *The influence of carbon dioxide on the oxygen uptake by fruits and vegetables* (p. 843).—It was found that when stored in 55 to 65 percent carbon dioxide with 20 percent oxygen dormant and nondormant potato tissues took up 83 and 239 percent more oxygen, respectively, onion bulbs 89 percent, tulip bulbs 11 percent, and beet roots 95 percent. On the other hand asparagus shoots, banana fruits, strawberry fruits, and shelled lima beans took up, respectively, 33, 17, 17, and 34 percent less oxygen. Within the range 8 to 72 percent of carbon dioxide there was no definite change in oxygen uptake of carrot roots. The duration of the exposure was an important factor.

IV. *The influence of carbon dioxide on the acidity of fruits and vegetables* (pp. 843, 844).—Storage in carbon dioxide resulted in an increase in alkalinity in the juices of plant tissues, the reduction in acidity increasing with the concentration of carbon dioxide and with the prolongation of the storage period. In the absence of oxygen the change in pH was not toward alkalinity but in the direction of increased acidity.

[**Vegetable crops at the New York Cornell Station**] (*New York Cornell Sta. Rpt.* 1932, pp. 160–162, 164–166).—Brief notes are made on the progress of studies of the premature seeding of celery; on fertilizer experiments with asparagus; on the use of green manures and cover crops in vegetable culture; on the selection and breeding of sweet corn to reduce or eliminate suckers; on fertilizer studies with muck soil crops; on the handling and storage of vegetables; and on place effect influences in seed beans.

Grading, packing, and stowing Florida produce, M. R. ENSIGN (*Florida Sta. Bul.* 254 (1932), pp. 59, figs. 29).—Of the 10 leading truck crops, string beans, cabbage, celery, cucumbers, eggplants, peppers, lettuce, white potatoes, tomatoes, and watermelons, only 3, namely, string beans, cabbage, and peppers, showed a favorable upward trend in production in the period from 1925 to 1931. The crop showing the greatest decline was lettuce, due primarily to an inability to grow the Iceberg variety successfully.

An analysis of causes of the present situation suggested that the use of the bulge pack is a potent factor. Not only do growers lose on the excess quantity put into overfilled containers, but the consequent damage to the produce and package opens the way for discounted prices, recoupage charges, and large damage claims, the last of which is chiefly of benefit to receivers and shippers. Breakage of containers in transit due to their inferior construction or to poor nailing and assembling was found excessive, and loose stowing and lack of correct bracing in the car adds greatly to the losses.

Various types of strong, light, and easily handled packages that display contents advantageously are described and illustrated. The proper methods of packing vegetables in these containers and of stowing containers in cars are pointed out, with the added suggestion that a strict adherence to the loading rules as specified in the Dulaney tariff, both as to assembling and nailing of the containers and to stowing and bracing of the load, would effectively reduce wastes.

Appended are the official United States and Florida standards for the grading of the principal fruits and vegetables.

Puerto Rico truck crops for exportation [trans. title], L. A. SERRANO (*Puerto Rico Dept. Agr. and Com. Sta. Circ.* 100 (1932), Spanish ed., pp. 10).—Information is presented on the volume and value of exports, the species and

varieties grown, time of planting, culture, important insects and diseases and their control, cost of production, etc.

Anatomy of *Phaseolus vulgaris* L. var. Black Valentine, M. T. DOURT (*Michigan Sta. Tech. Bul. 128 (1932)*, pp. 31, pls. 8).—Accompanied by photomicrographs and drawings, there are presented the results of studies of the gross morphology, anatomy, ontogeny, and the course of the vascular bundles in a horticultural variety of the cultivated garden bean.

Commercial cabbage culture, V. R. BOSWELL (*U.S. Dept. Agr. Circ. 252 (1933)*, pp. 59, figs. 21).—Designed primarily to present a few typical practices, together with some less commonly known information and principles which underlie successful production, this circular discusses among other points the effects of temperature, characterizations of the more important varieties, seed, soil preparation, culture in various important producing areas, harvesting, storing, grading, and pest control. The section on insects was prepared with the assistance of W. H. White and that on plant diseases by J. C. Walker.

Results of experimental work on the growing of cucumbers in electrically heated soil, J. R. TAVERNETTI and H. A. JONES (*California Sta., Calif. Com. Relat. Elect. Agr., Prog. Rpt. 20 (1933)*, pp. 10, figs. 9).—Presented as a joint contribution of the station and the California Committee on the Relation of Electricity to Agriculture, this mimeographed report states that attempts to grow cucumbers during the winter months in muslin covered frames heated by electricity were unsuccessful because of the low air temperature. Soil heating both in frames and in the field in the spring tended to hasten maturity but not to an economically important degree. In two tests the proportion of first grade cucumbers was increased, in one instance decreased, and in one case equaled by soil heating. Seed germinated faster and the plants grew more rapidly in the heated beds.

Growing and marketing muskmelons, J. W. LLOYD (*Illinois Sta. Circ. 405 (1933)*, pp. 20, figs. 6).—Replacing Bulletin 124 and Circular 139 (E.S.R., 20, p. 146; 23, p. 42), general information is presented on culture, control of pests, varieties, harvesting, marketing, etc.

The effect of certain mineral elements on the color and thickness of onion scales, J. E. KNOTT (*New York Cornell Sta. Bul. 552 (1933)*, pp. 14, pls. 2).—Observing that many areas of muck soil in New York produce onions of poor color and with thin scales, experiments were conducted in the green house with soils obtained from locations producing, respectively, well and poorly colored onions. Analyses showed 19.53 percent ash and 31 p.p.m. of copper in the soil producing well colored onions and 14.9 percent ash and 12.5 p.p.m. of copper in that producing poorly colored bulbs. A total of four crops, two of Ebenezer sets and two of Yellow Globe Danvers seed, were grown. Scale thickness was increased and color enhanced in the first two crops by increased quantities of superphosphate. In the second crop onions receiving a total of 200 lb. per acre of copper sulfate produced the thickest scales and the best color. The same situation obtained with the seeded crops.

In 1930 field trials in Orange County in which copper sulfate and manganoous sulfate were applied at the rate of 100 lb. per acre, the former had a slight effect on color and the latter none. In 1931 where muriate of potash and superphosphate were used in heavy quantities on a recently cleared muck, the color was best where phosphoric acid was applied. No evidence was seen that potash improved color over that produced by the basic fertilizer. From these results and those obtained in the greenhouse the author suggests the possibility of improving scale color and thickness by the use of large amounts of superphosphate. It is believed that the fertilizer applications

commonly used do not provide sufficient phosphorus to influence the color of onions on mucks where color is deficient.

In field experiments in 1932 the application of 100 lb. per acre of monohydrate copper sulfate gave a significant increase in scale thickness. In 11 of 18 trials, 200 lb. per acre further increased scale thickness, but none of four plats receiving 300 lb. per acre showed a significant increase above the 200-lb. plats. Onions grown on soil supplied with copper were firmer than those not so treated. The effect of copper on scale color was equally as striking as that on thickness. The response in both thickness and color of scales indicated an interaction between the causal factors, among which water is conceded important.

Seed of selfed bulbs of good and poor color growing on muck where color was only fair produced uniformly poorly colored bulbs when sown on a soil normally producing poorly colored onions. A test of a number of varieties and strains on both good and poor coloring soils further suggested that inferior color is an environmental rather than a genetic reaction.

Spinach early and late, J. W. LLOYD (*Illinois Sta. Circ. 404* (1933), pp. 8, figs. 5).—General information is presented on the culture and handling of spinach, including the New Zealand type.

The composition of canning tomatoes, L. G. SAYWELL and W. V. CRUESS (*California Sta. Bul. 545* (1932), pp. 32, fig. 1).—Working with tomatoes procured from four regions differing widely in prevailing summer temperatures and humidity, it was found that fruits from the cool, foggy climate of the San Francisco Bay region were considerably higher in total solids than those grown in warmer localities; in fact, in general the higher the average summer temperature the lower the total solids. The average total solids content of all samples from southern California for a 5-year period was 0.55 percent lower than that of northern California samples.

Based on published data, California tomatoes appeared to be higher in total solids than those grown in the eastern United States. November ripened tomatoes were lower in total solids than those maturing in October and September, and in most seasons total solids were somewhat higher in the October pickings than in the September. That soil moisture was also a factor was shown in higher total solids in fruit from plants suffering from a lack of water.

Among varieties, Stone was consistently higher in total solids and total acids, and Early Canner was also high in total solids. Seed selection within a variety yielded strains differing in composition of fruit, and in fact fruits from adjacent plants or from different locations on a single plant varied considerably.

Analyses of the different parts of a fruit showed the locular tissues to be higher in total acid and slightly lower in total solids, reducing sugars, and proteins than the cores and walls. The cores were the highest in total solids and reducing sugars. The acid-hydrolyzable material was much lower in the locules than in the walls and cores. The average protein content of samples from 3 years' collections was 0.97 percent. Less than 0.05 percent of the sugars which constituted about half the total solids was sucrose, and the starch content of the pulp was also very low. Pectin content varied considerably with variety, time of picking, locality, and degree of ripeness. The average pH value of the 1925 samples was 4.1, the range being mostly between 4 and 4.2.

[**Pomology at the New York Cornell Station**] (*New York Cornell Sta. Rpt. 1932*, pp. 114, 150–152).—Brief comments are given on the results of studies in

pruning; orchard soil management; apple pollination; the nature and cause of winter injury to fruit tree roots; the effect of water-logged soils on photosynthetic activity; the relation of storage temperature to the keeping of apples; the comparative efficiency of oiled wrappers and shredded paper in the control of apple scald; the development of red color in apples after harvesting; and, by A. G. Rodriguez, on the influence of smoke and ethylene on the fruiting of the pineapple.

Field studies of bud sports in Michigan tree fruits, B. D. DRAIN (*Michigan Sta. Tech. Bul. 130 (1932), pp. 48, figs. 18*).—As part of a general program to determine the types, frequency, and importance of bud variations in deciduous tree fruits, the author presents the results of an intensive search of Michigan orchards in which were discovered many variant types, particularly among apples and sour cherries. Many of these off types are described.

As the work progressed, evidence was found that such variations are rather common instead of rare, although more off types were found in some varieties than in others. The numbers corresponded rather closely to the total number of trees observed and the time spent in studying them. Certain of the variants differed from the parent in only one character, such as color of the fruit, while others differed in two or more characters, such as season of ripening, habit of tree growth, etc. It was apparent that bud sports extend to most, if not all, of the characters of the tree and fruit. There was observed a tendency for certain types of variations to be associated with certain others; for example, gigantism in the fruit of the apple was associated with a distinctly spreading habit of tree.

No evidence was found that environment plays a role in the development of bud variations. Some, such as color mutations in apples, were rather obviously sectorial chimeras. Others, such as in the case of one russeted pear, might be classified as periclinal, mottled, or mosaic type chimeras, and still others did not fall in either group.

Viewed from the standpoint of actual value, a large percentage of the bud sports were of little or no merit, while some, especially red fruited mutations, appeared highly valuable. However, because asexual propagation is employed in fruit tree production the practice of selecting buds from trees of known characteristics and performance is obviously desirable, since such choice tends to eliminate worthless and undesirable variations and promotes uniformity within any given variety.

Deciduous-fruit improvement through tree-performance records, A. D. SHAMEL and C. S. POMEROY (*U.S. Dept. Agr., Farmers' Bul. 1696 (1933), pp. II+18, figs. 9*).—Stating that investigations of extensive plantings of young peaches, pears, prunes, and apricots have shown that the frequently occurring off type trees are often the results of unintentional propagation of limb variations in the parental trees, the authors classify such variations as fluctuations due to environment and as true variations which persist and may be propagated. Examples of the permanent type of variations found in apple, pear, peach, and plum orchards are illustrated and discussed, and a method of discovering such variations by use of individual tree records is described in considerable detail. Striking variations, such as color mutations and changes in the type of foliage, may be determined by careful inspection of the trees. The heritability of variations may be established by top-working in older trees or by budding of young nursery stock. The use of buds from vigorous, high yielding trees bearing fruits of desirable type is said to have given excellent results with citrus and should prove equally valuable with deciduous fruits.

Soils in relation to fruit growing in New York.—II, Size, production, and rooting habit of apple trees on different soil types in the Hilton and

Morton areas, Monroe County, J. OSKAMP and L. P. BATJER (*New York Cornell Sta. Bul. 550 (1932), pp. 45, figs. 42*).—This, the second phase (E.S.R., 68, p. 591) of a study upon the relation of soil to fruit growing, presents the results of soil examinations in representative old and young Baldwin orchards and leads to the conclusion that a definite relationship exists between stand, yield, size, vigor, and rooting habit of Baldwin trees and the drainage conditions as expressed by a study of the soil profile relative to color, texture, structure, percolation, and ground water. The highest yields and generally most satisfactory conditions were found in orchards located on soils of a uniform brown to slightly mottled profile without marked contrasts between horizons. Such soils were usually medium to light in texture and underlain with deep subsoils, which permitted a ready downward movement of water. On the other hand, unproductive orchards were usually located on below medium to heavy soils underlain with a slow-draining subsoil at 2 ft. or less from the surface. The most unfavorable orchard location seemed to be where shallow rooting was accompanied by a high ground water level or by a high ground water level in connection with a gravelly till substratum.

Roots of mature Baldwin apple trees penetrated from 2.5 to 8.5 ft., depending on the character of the subsoil. In all of the soils studied about 60 to 70 percent or more of the roots were in the upper 16 in. That the deeper roots were important factors is indicated by the fact that practically all of the deep rooted orchards were productive.

Relation of leaf area and position to quality of fruit and to bud differentiation in apples, M. H. HALLER and J. R. MAGNESS (*U.S. Dept. Agr., Tech. Bul. 338 (1933), pp. 36, pl. 1, figs. 8*).—Asserting that the supply of carbohydrates available to the fruit depends primarily on the amount of carbohydrates elaborated per fruit and on the transport of carbohydrates to the fruit, the authors present the results of experiments with apples grown on both ringed and unringed branches supplied with different leaf areas per apple and with a given leaf area at different distances and in different directions from the fruit.

In general on unringed branches variations in leaf area had no appreciable effect on the composition of the fruit and very little influence on size.

On ringed branches on the other hand, increased leaf area was accompanied by increased fruit size. However, even with small leaf areas the increased fruit size was not proportional to the leaf increase. Maximum fruit size was usually obtained with about 30 leaves per fruit. With relation to leaf location, apples apparently secured elaborated foods with equal facility from leaves above or below, or even on separate branches. Practically no reduction in size or composition of the fruit occurred when all leaves were removed to a distance of 4.5 ft. in Grimes Golden, 6 in Ben Davis and York Imperial, 6.5 in Jonathan, and 10 ft. in Baldwin, as compared with fruits grown with the same number of leaves immediately adjacent.

As regards composition, the percentage of dry weight and of total sugars increased in fruit of ringed branches with increased leaf area. Good dessert quality was associated with high total sugars. Color, both ground and overlying, was inferior in fruits with a small number of attendant leaves. In Ben Davis firmness after storage decreased with an increase in leaf area per apple, and in Baldwin, Jonathan, and York Imperial apples decreased in firmness with increased leaf area up to about 20 leaves, but above this point firmness increased with increased leafage.

Blossom bud formation was inhibited on ringed branches with few leaves but occurred freely with larger leaf areas. Blossom bud formation was associated

with a relatively high sugar content in the adjacent apples. Thinning treatments as late as June 25 greatly influenced blossom bud formation.

Factors causing cull apples in Missouri. G. C. SCHOWENGERDT and D. C. WEST (*Missouri Sta. Bul. 319 (1932), pp. 30, figs. 9*).—Investigations conducted in representative orchards in southwestern and northwestern Missouri showed that small size of fruit was the leading cause of low grade apples in both areas in 1928 and 1929. Among other important factors concerned were mechanical injuries, insufficient color, injuries from codling moth, curculio, aphids, scab, blotch, and cedar rust, and sprays. In certain seasons hail and frost also caused losses.

As concerns locality, in 1928 most of the varieties of apples studied graded out somewhat better in southwestern than in northwestern Missouri. In 1929 the situation was reversed, with far better fruit in the northwestern section. In both years a higher price was obtained for all grades of apples in the northwestern area. In general Grimes Golden and Jonathan commanded the best prices.

Ways and means of overcoming most of the major factors lowering the grade of apples are discussed.

Relation of growth cycle to toxicity of wound dressings. J. S. COOLEY and J. H. CRENSHAW (*Amer. Jour. Bot., 19 (1932), No. 10, pp. 842, 843*).—Working in the Hood River Valley, Oreg., there was noted a very pronounced killing of apple tissues in the autumn by very mild wound dressings which in the spring caused only slight or no injury to the same type of wounds. This demonstrated a close relationship between resistance to toxic dressings and the vital processes in the plant.

Correlation of specific heat and percentage of water in apple wood. A. L. STARK (*Plant Physiol., 8 (1933), No. 1, pp. 168-170, fig. 1*).—Studies at the Iowa Experiment Station upon 15 apple varieties showed that the specific heat of the wood may be calculated directly from the water content. From 65 observations on current season apple shoots collected at intervals in the period May to December 1931, there was determined a correlation of $+0.9475$ between specific heat and percentage of water in the wood. A scale showing the relation of specific heat and the percentage of water is presented.

Preparing apples for market in barrels and baskets. R. R. PAILTHORP and J. W. PARK (*U.S. Dept. Agr., Farmers' Bul. 1695 (1933), pp. [2]+34, figs. 26*).—This bulletin, a revision of and superseding Farmers' Bulletin 1080 (E.S.R., 42, p. 39), presents information on harvesting, grading, packing, transportation, cold storage, etc.

The Babcock peach. G. P. WELDON and J. W. LESLEY (*California Sta. Circ. 328 (1933), pp. 5, figs. 2*).—This new peach, a second generation hybrid from an original cross between the Strawberry, a variety extremely subject to prolonged dormancy, and a variety of the Peento group, much less susceptible to this trouble, is described and discussed. The new peach combines resistance to delayed foliation and some of the desirable qualities of the better types of peaches.

The Fertile Hale peach. S. JOHNSTON (*Michigan Sta. Quart. Bul., 15 (1933), No. 3, pp. 181, 182*).—A description is presented of a self-fruitful and vigorous peach found among a shipment of J. H. Hale trees received from a commercial nursery. The fruit resembles J. H. Hale very closely but ripens some three days later and is not as bright in appearance. The quality is considered very good.

Seasonal absorption of nutrient salts by the French prune grown in solution cultures. H. L. COLBY (*Plant Physiol., 8 (1933), No. 1, pp. 1-34, figs. 8*).—In this study at the California Experiment Station there was determined

the course of seasonal nitrate absorption and of elemental starvation in 1- and 2-year-old French prune trees growing in water cultures in the greenhouse. In 1929 the primary peak in nitrate absorption in complete nutrient solution trees occurred near the end of June, with a final secondary peak in late October, followed by a rapid decline to winter rest. In 1930 the maximum was reached at about the same season. Potassium absorption closely followed nitrate, except for a slight lag in the early part of the season. The rate of nitrate and potash absorption was closely associated with temperature and probably also with light intensity.

Of the six major elements other than nitrogen in the solution, namely, sulfur, iron, potassium, magnesium, phosphorus, and calcium, sulfate starvation apparently exerted by far the least depressing effect on nitrate absorption. Iron starvation was not studied. Potassium, magnesium, and phosphorus starvation all seriously depressed nitrate absorption, even to the extent of a loss of nitrate from the roots in the late season. Calcium starvation prevented root growth altogether, although roots previously well stocked with calcium survived somewhat longer. The total phosphate absorption for the season was far more depressed by magnesium starvation than by a lack of potassium or sulfur. Calcium starvation apparently prevented the absorption of any considerable amount of any ion, including phosphate.

The Potomac raspberry, G. M. DARROW and G. F. WALDO (*U.S. Dept. Agr. Circ. 259 (1933), pp. 4, figs. 2*).—A brief descriptive account is given of a new raspberry originated at the U.S. Plant Field Station near Glenn Dale, Md., from a cross of the Farmer black raspberry and the Newman red raspberry. This new fruit is said to have wide adaptation because of its hardness and resistance to leaf spot and anthracnose diseases.

The Dorsett, Fairfax, and Narcissa strawberries, G. M. DARROW and G. F. WALDO (*U.S. Dept. Agr. Circ. 257 (1933), pp. 7, figs. 3*).—Accompanied by information on parentage, brief descriptions are given of two new varieties developed at the U.S. Plant Field Station near Glenn Dale, Md. The third variety mentioned, namely, Narcissa, was described in Oregon Experiment Station Circular of Information 79 (E.S.R., 68, p. 621).

Results of strawberry fertilizer and tillage experiments, R. A. LINEBERRY, J. J. SKINNER, H. B. MANN, and C. B. WILLIAMS (*North Carolina Sta. Agron. Inform. Circ. 75 (1933), pp. [3]+26*).—This is a preliminary report of studies conducted at Chadbourn, N.C., during the three seasons ended 1931-32 in cooperation with the U.S.D.A. Bureau of Chemistry and Soils. Among observations were that fertilizer mixtures containing more than 6 percent ammonia gave a comparatively large percentage of faulty and soft berries. Large amounts of potash decreased yields but in many instances improved the quality of the fruit. Considering both yield and quality, a mixture containing 8 percent phosphorus, 6 percent ammonia, and 6 percent potash was most effective. There were indications that physiologically acid fertilizers, such as ammonium sulfate, may be more beneficial to strawberries on neutral or slightly acid soils, and that physiologically alkaline fertilizers, such as nitrate of soda, may be more favorable on very acid soils.

Fredonia, a promising blue grape for early market, N. L. PARTRIDGE (*Michigan Sta. Quart. Bul. 15 (1933), No. 3, p. 183*).—Descriptive comments are made on a new grape originated by the New York State Experiment Station at its Fredonia laboratory from a cross of Champion and Lucile.

Neophytosis of rejuvenescence of nucellar bud seedlings in citrus, W. T. SWINGLE (*Amer. Jour. Bot., 19 (1932), No. 10, p. 839*).—The fact that recently originated ovary-sterile hybrids reproduce almost exactly the original F₁ seed-

lings while old cultivated varieties usually exhibit marked rejuvenescence is explained on the theory that hormones secreted in the embryo sac apparatus force into activity the genes governing embryonal ontogeny.

Physiological anatomy, type, variety, and maturity of citrus fruits as affecting quality of prepared juices, H. P. TRAUB, L. W. GADDUM, A. F. CAMP, and A. L. STAHL (*Plant physiol.*, 8 (1933), No. 1, pp. 35-80, fig. 1).—In this study, conducted cooperatively by the U.S. Department of Agriculture and the Florida Experiment Station, it was found that the cause of the bitter taste developing in prepared citrus juice is of glucosidal origin and is localized primarily in the inner peel, veins, and locular wall tissues. The degree of development was a function of fruit maturity, citrus type and variety, method of preparation, and after treatment. The kind of bitter taste was associated with the nature of the glucoside contained in the specific type of fruit. The causal agent for color changes in prepared citrus juices was identified as citrus oil from the outer peel, and within the limits of the experiments the amount and rate of color changes were to a marked degree proportional to the quantity of citrus oil present.

The tendency of prepared citrus juices to develop bitter flavor was found dependent on the age of the fruit, decreasing with maturity. This fact harmonized with the known decrease in glucoside content of citrus with maturity.

Concerning the stability of the suspension, a reduction in size of suspended particles by grinding, etc., improved stability and lightened the color of the product. In prepared juice part of the suspended particles rose and part settled, but following vacuumization all particles settled. Preliminary results suggested that rates of freezing had a greater effect on stability of the suspension than did variations in storage treatment. Quick freezing and cold storage did not materially affect the rate of movement of the suspended particles as compared to fresh juice. Very large amounts of citrus oil caused all particles to rise.

Asiatic chestnut (*New York Cornell Sta. Rpt. 1932, p. 129*).—Notes are presented on the poor survival of Asiatic chestnuts following planting.

[Floriculture at the New York Cornell Station] (*New York Cornell Sta. Rpt. 1932, pp. 127-129, 143*).—Brief statements are made as to the results of studies on the control of gladiolus thrips; on the effect of aluminum on the color of hydrangea flowers; on photoperiod effects on the blooming of chrysanthemums and other plants; on the value of muslin coverings for such summer annuals as calendulas, asters, and dahlias; on the rooting of evergreen cuttings; on storage of seeds of ornamental woody plants; on fertilizer and planting studies with shade trees; on paper mulching of evergreens; on the use of paraffin for coating balled and burlapped evergreens; and, by M. F. Barrus and H. W. Rankin, on the propagation of the snowberry.

FORESTRY

[Forestry at the Indiana Station] (*Indiana Sta. Rpt. 1932, pp. 41-43, figs. 2*).—Brief reports are given on the progress of studies in the marketing of woodland products, such as crossties and piling, and on the establishment of windbreaks, the effect of which on wind velocity and temperature is presented in tabular form.

[Forestry at the Ohio Station], E. SECREST, O. A. ALDERMAN, B. E. LEETE, E. G. WIESEHUEGEL, R. R. PATON, and F. W. DEAN (*Ohio Sta. Bul. 516 (1933), pp. 113-122, figs. 2*).—Reports are made of work in reforestation; management of the State forests and parks; control of forest fires; forest regeneration;

timber prices in Ohio; classification of forest lands; and the handling of farm woodlots.

Peat mats for germination tests of forest tree seeds, P. C. WAKELEY (*Science*, 76 (1932), No. 1983, pp. 627, 628, fig. 1).—Peat moss compressed into mats or blocks was found in tests conducted by the U.S.D.A. Southern Forest Experiment Station with *Pinus caribaea* seeds to give not only prompter but usually higher final germination than was obtained in sand. Peat moss mats occupied much less space than sand flats, and adequate moisture content was more readily maintained. A description is given of the apparatus.

The effect of forest burning on reproduction [trans. title], N. M. TŪL'PANOV (TŪLPANOFF) (*Trudy Lesotekh. Akad. (Mitt. Forsttech. Akad. Leningrad)*, 38 (1931), No. 1, pp. 50-60; *Ger. abs.*, pp. 59, 60).—Stating that Hofmann's findings (*E.S.R.*, 38, p. 145) on the importance of forest fire in the regeneration of Douglas fir first drew attention to the importance of soil-stored seeds, the author discusses experiments conducted by the Leningrad Forestry Institute in which areas previously seeded with Scotch pine were burned over under conditions which permitted the recording of temperatures of the soil at various depths. In one experiment, where the temperature reached 362° C., 33 percent of the seed showed no external injury and germinated 12 percent. In a second test, where the temperature reached 182°, 95 percent of the seeds was severely injured and the viability was only 0.1 percent.

Hardwood invasion in a comparatively old white pine afforested area, V. A. YOUNG (*Ecology*, 14 (1933), No. 1, pp. 61-69, figs. 4).—A small white pine stand, located near Syracuse, N.Y., and kept free from hardwoods until 1894, was subsequently rapidly invaded by a dense and overpowering growth of hardwoods, which had to be removed in 1931 in order to save the pine. Hardwoods are considered the most destructive biotic enemy of afforested conifer areas in New York State, particularly those stands located on soils not wholly adapted to pine. Small coniferous stands do not provide a sufficiently dense shade to check hardwood invasion.

Forest associations in the uplands of the lower Gulf coastal plain (longleaf pine belt), L. J. PESSIN (*Ecology*, 14 (1933), No. 1, pp. 1-14, figs. 8).—The conclusion is reached that the forest associations of the region are determined largely by the prevailing edaphic conditions; for example, on sterile, well drained, dry sands, after longleaf pine is removed the typical xerophytic scrub oaks predominate. Some plants are excellent indicators of the moisture condition of the soil; for example, the gopher apple indicates dry soil, while wax-myrtle thrives best on moist soil.

Soil temperatures and evaporation in a paper birch-white pine forest, Long Lake, Hamilton County, New York, H. I. BALDWIN (*Ecology*, 14 (1933), No. 1, p. 75).—Stated as an average of weekly averages, the soil temperature at a 1-ft. depth during the period June 27 to August 28 was 55.7° F. in the woods and 61.8° in the open. Evaporation measured by Livingston atmometers placed 6 in. above the soil was 83.2 cm per week in the open and 34.5 cm in the woods.

[Tree species tested by the Iowa Station], G. B. MACDONALD (*Iowa Sta. Rpt.* 1932, p. 97, fig. 1).—The black locust is discussed with respect to its value in preventing erosion.

Soil erosion and tree planting, E. SECREST (*Ohio Sta. Bimo. Bul.*, 18 (1933), No. 2, pp. 30, 31, figs. 2).—Soil erosion was found to be checked not so much by the roots of trees as by the accumulation of needle litter, which matted closely to the ground, increased the water absorptive capacity of the soil, and at the

same time shed surplus run-off of water. Among species proving best for reclamation were red, white, and Scotch pines in the northern part of the State and shortleaf and pitch pines in the southeastern portion. The black locust proved well adapted for reclaiming eroded limestone soils. Where soils are badly gullied 4-year transplants are conceded most desirable and should be spaced no farther apart than 6 by 6 ft.

Using soil-binding plants to reclaim gullies in the South, H. G. MEGINNIS (*U.S. Dept. Agr., Farmers' Bul. 1697 (1933), pp. II+18, figs. 15*).—Asserting that millions of acres throughout the uplands of the South are eroding at an appalling rate, the author discusses the planting of trees, vines, grasses, and other plants as a means of preventing erosion. The restoration of the forests is deemed the climax process for reclaiming areas denuded by gullying. However, the construction of brush barriers and the planting of rapidly growing plants must usually precede actual reforestation.

Making spruce-fir land profitable, R. H. WESTVELD (*Michigan Sta. Quart. Bul., 15 (1933), No. 3, pp. 172-174*).—Asserting that one of the most destructive forces in cutting operations is carelessness in logging, which destroys large quantities of young growth, the author presents tabulated data on the percentage of seedlings destroyed in logging operations on two typical spruce areas of northern Michigan. The average losses ranged from 57.7 to 95.7 percent. In one operation 39 percent of the surface was covered by logging roads upon which all seedlings were killed. Suggestions for reducing such losses are given.

The economic significance of tree size in western Sierra lumbering, M. R. BRUNDAGE, M. E. KRUEGER, and D. DUNNING (*California Sta. Bul. 549 (1933), pp. 61, figs. 25*).—In cooperation with the U.S.D.A. Forest Service a coordinated logging and milling study was conducted in a typical virgin stand of Site 1, west slope, California pine region timber consisting of sugar pine, ponderosa pine, white fir, and incense cedar trees of all ages and sizes.

Evidence was secured that operators are cutting many trees below a profitable minimum size. The cost of felling, limbing, bucking, yarding, loading, decking, unloading, and sawing increased as the tree diameter decreased, the cumulative effect of these increases becoming so pronounced in the smallest classes that the total of all costs was approximately twice as great for lumber from 14-in. as from 40-in. trees.

In all species lumber from 40-in. trees exceeded production costs when fixed acre charges and stumpage charges were excluded. The average minimum profitable diameters in white fir, incense cedar, sugar pine, and ponderosa pine were 34, 28, 23, and 22 in. in diameter at breast height, respectively. Disregarding species, the average minimum tree diameter cutting limit to give the greatest margin per acre was 28 in.

In conclusion the authors assert that the cutting system for each logging operation must be determined from the stand at hand, the local situation, and the particular objectives of management. The leaving of small trees which can not pay for their handling is a practice which should be universally adopted by lumbermen purely on its merits as an operating economy.

Woodsman's manual, A. CARY (*Cambridge: Harvard Univ. Press, 1932, 4. ed., pp. [X]+366, pls. 3, figs. 75*).—As in the earlier editions (E.S.R., 51, p. 842), herein is presented information on the principles and practices of land surveying, forest mapping, log and wood mensuration, timber estimating, etc.

Logging methods (*California Sta. Rpt. 1932, p. 69*).—The results of studies of logging operations in the redwood and pine regions are briefly discussed.

DISEASES OF PLANTS

[Plant disease studies in California] (*California Sta. Rpt. 1932, pp. 33-37, 46-49, 56-58, figs. 5*).—Data are reported as to findings on black end of pears; little leaf disease of fruit trees; prune die-back; potato virus diseases; pink root of onions; resistance in wheat to bunt, in alfalfa to wilt, and in lima beans to nematodes, wireworms, *Fusarium* rot, and heat; carrot soft rot; cantaloup powdery mildew; potato calico; diamond canker of the French prune; crown rot and blight of walnuts; fig diseases; sun blotch of avocado; and decline disease of dates.

[Plant disease studies in Delaware] (*Delaware Sta. Bul. 179 (1932), pp. 43-55, figs. 2*).—Data are briefly noted on control of tomato seedling diseases, soil disinfectants for control of black rot and other sweetpotato seed bed troubles, and relation of the periodical cicada to dissemination of peach yellows and little peach, all by T. F. Manns, and diseases of canteloups and soybeans, bacterial spot of stone fruits, spray materials, and a root infection of strawberry plants, all by J. F. Adams.

[Plant disease studies by the Georgia Coastal Plain Station] (*Georgia Coastal Plain Sta. Bul. 19 (1932), pp. 62, 63, 65, 66, 93-97, fig. 1*).—Data are briefly reported as to findings from spraying for nail head blight (*Alternaria solani*) of tomatoes and for downy mildew of canteloups and from root knot of tobacco, downy mildew (blue mold), and other tobacco diseases.

[Plant disease studies in Indiana] (*Indiana Sta. Rpt. 1932, pp. 25-28, 55, 56, figs. 2*).—Findings are briefly reported as to developing resistance to bacterial wilt disease in sweet corn; clover mildew investigations; bacterial canker of tomato; effect of leaf rust on yield, quality, and chemical composition of winter wheat; the relation of appressorium formation and host penetration by leaf rust of wheat to stomatal aperture; cereal scab investigations; tomato virus diseases; and apple blotch.

[Plant disease studies in Iowa] (*Iowa Sta. Rpt. 1932, pp. 32-40, 42-45, fig. 1*).—Results are briefly reported of work on inheritance of resistance to *Basisporium* ear rot and seed rotting and the relation of these characters to yield, by C. S. Reddy and E. W. Lindstrom; biology and control of *Colletotrichum lagenarium* on species of Cucurbitaceae, by D. V. Layton; breeding and selection of resistant strains of melons, by J. J. Wilson; physiological specialization and parasitism of crown rust of oats, and the making of new strains of oats resistant to crown rust by selection and hybridization, both by H. C. Murphy; the control of seed and soil-borne diseases of the potato, by Reddy; pathogenicity, host response, and control of leaf spot of sugar beets, by E. F. Vestal; breeding of sugar beet strains resistant to *Cercospora* leaf spot, host range, and intertransmissibility of species of *Cercospora*, by S. M. Dietz; diseases of sugar beets caused by species of *Phoma*, *Rhizoctonia*, *Pythium*, etc., in their relation to the *Cercospora* leaf spot disease, by Reddy; breeding for resistance to cabbage yellows, by Wilson; development and testing of dust fungicides for control of seed-borne diseases of wheat and oats, by Reddy; classification of plant viruses, by R. H. Porter; propagation of disease-free sweetpotato seed stock, by Layton; the pathogenicity and morphology of the genus *Gymnosporangium* in Iowa, and the control of nursery diseases, both by G. L. McNew; onion bulb rot and yellow dwarf, by I. E. Melhus and W. J. Henderson; factors influencing resistance of strains of corn to *Ustilago zeae*, by Melhus and G. N. Davis; *Diplodia* dry rot of corn and its treatment, by Melhus and Reddy; and pathogenicity of *B. gallarum* to corn, by Reddy.

[Plant disease studies by the New York Cornell Station] (*New York Cornell Sta. Rpt. 1932, pp. 113, 114, 131-149, 152*).—Results are briefly noted of

studies by D. Reddick on the transmission of the virus of bean mosaic by pollen and diseases of wild potatoes in Mexico; by Reddick, W. F. Crosier, and W. D. Mills on blight immune potato hybrids; by C. G. Small on dusting for the control of fruit diseases; by F. M. Blodgett et al. on factors affecting the efficiency of spraying and dusting operations with potatoes and treatment of seed potatoes with mercury compounds, control of potato scab, and virus diseases of the potato; by C. Chupp and G. F. MacLeod on spraying and dusting cucumbers; by Mills on apple scab; by A. G. Newhall et al. on attack of onions by the bulb nematode (*Tylenchus dipsaci*); by Newhall on the development of a forcing-house tomato resistant to *Cladosporium* leaf mold and lettuce tipburn; by G. R. Townsend on control of bottom rot of lettuce; by W. W. Stuart on downy mildew of lettuce; by A. L. Harrison on celery blights; by Newhall on *Phoma* root rot of celery; by D. S. Welch on activities of microorganisms in living trees; by F. L. Drayton on the sexual function of the microconidia in *Sclerotinia gladioli*; by F. Dickson on *S. sclerotiorum*; by H. H. Whetzel and Drayton on *Botrytis* rhizome rot of iris; by L. M. Massey on *C. cyclaminis* n.sp., the causal fungus of the stunt disease of cyclamen; by Welch on a canker disease of basswood and other deciduous trees; by D. K. O'Leary on diseases of lilies; by C. E. F. Guterman and W. H. Burkholder on bacterial leaf spot of carnations and ivy; by Guterman on control of *Botrytis* blight of calendula and snapdragon and control of soft rot and root rot of the calla lily; by F. A. Haasis and F. Weiss on mosaic and "fire" of narcissus; by D. L. Gill on a leaf nematode disease of begonia and a cutting rot of geraniums; by M. F. Barrus and H. W. Rankin on anthracnose of snowberry and seed treatment of Alpha barley to control loose smut; by Burkholder and J. W. Sinden on the physiology of the alpha, beta, and gamma races of *Colletotrichum lindemuthianum*; by A. B. Burrell on cork disease of apple; by Burkholder and K. Zaleski on varietal susceptibility of beans to *Phytophthora medicaginis phascolicola*; by Chupp on drought injury to cabbage; by F. M. Clara on *Pseudomonas utiformica* n.sp. as the causal organism of a new bacterial disease of pears; by Mills on leaf rust of raspberries caused by *Pucciniastrum americanum*; by Mills and W. E. Blauvelt on fruit scald and leaf scorch; by B. Parsons and Massey on control of rose diseases; and blue mold injury to apples.

[Plant disease studies in Ohio] (*Ohio Sta. Bul.* 516 (1933), pp. 37-42, 43-45, fig. 1).—Data are reported on sulfur sprays for apple scab, by H. C. Young and H. F. Winter; colloidal sulfur toxicity and its enhancement, by Winter and Young; diseases of coniferous seedlings, by C. May; control of leaf spot and blight of carrots, by J. D. Wilson; control of gladiolus scab, by P. E. Tilford; use of formaldehyde dust in tobacco seed beds, by L. J. Alexander; Dutch elm disease, by May; potato spraying with Bordeaux mixture, by Tilford; use of formaldehyde dust in improving the stand of vegetables, by Wilson; chemical treatment of fire blight cankers, by R. C. Thomas; control of raspberry virus disease, by Winter; resistance of celery varieties to yellows, by Wilson; influence of Bordeaux and oil sprays on the water relations of plants, by Wilson and H. A. Runnels; and determination of the phenol coefficients of bactericides, by Thomas.

Biologic forms of *Albugo candida* (Pers.) Kuntze on some cruciferous plants, M. HIRUA (*Japan. Jour. Bot.*, 5 (1930), No. 1, pp. 1-20).—In studies carried out in 1928 regarding the existence of biologic forms in *A. candida*, the fungi occurring on radish (*Raphanus sativus*), on aburana (*Brassica chinensis*), and on Chinese mustard (*B. juncea*) were inoculated onto cruciferous plant varieties named.

It is claimed to have been shown that the *A. candida* from *R. sativus* can infect all the radish varieties tested, but that no other crucifer tested was so

infected; that the fungus infecting *B. chinensis* can infect with different degrees of severity *B. japonica*, *B. chinensis komatsuna*, *B. rapa*, *B. chinensis ampleiacaulis*, *B. pekinensis*, *B. juncea*, and the original host; and that the fungus on Chinese mustard (*B. juncea*) can infect *B. cernua*, *B. chinensis*, and its original host with different degrees of severity, but not radish. It is therefrom concluded that these three fungi are distinct biologic strains of *A. candida*.

No marked differences in conidial size have been noted among the fungi attacking respectively radish, aburana, and takana (Chinese mustard), but the form on shepherd's purse (*Capsella bursapastoris auriculata*) bears smaller conidia. The incubation period ranged ordinarily from 7 to 10 days, but from 1 to 2 days longer in less susceptible varieties.

Experiments with *Bacterium tumefaciens* [trans. title], T. H. THUNG (*Tijdschr. Plantenziekten*, 35 (1929), No. 10, pp. 263-269, pl. 1; *Eng. abs.*, p. 268).—Inoculations of celery roots with *B. tumefaciens* resulted in the formation of abortive leaves and roots, probably only on the galls which formed.

The question as to the possibility of artificial immunization of plants was not settled by the experimentation here reported. Results of tests with *Ricinus communis* and *B. tumefaciens* were also negative.

No toxin similar to that of *B. tumefaciens* for plants was obtained from bouillon cultures kept for 3, 8, 14, or 28 days.

"Cultures of *B. tumefaciens* which are ultra-pure in the sense of d'Hérelle may produce tumors in plants. This is contradictory to d'Hérelle and Peyre's hypothesis on the formation of galls. The writer favors Magrou's hypothesis on gall-formation as a consequence of the action of mitogenetic rays, radiated by *B. tumefaciens*."

The life history and physiology of *Synchytrium fulgens* Schroet., with special reference to its sexuality, S. KUSANO (*Japan. Jour. Bot.*, 5 (1930), No. 1, pp. 35-132, figs. 19).—As a result of a study bearing upon the old question whether sexual reproduction occurs in *S. fulgens*, the author contends that it does take place. The processes concerned or related are set forth in some detail.

Effects of certain environmental factors on stripe disease of barley and the control of the disease by seed treatment, R. W. LEUKEL, J. G. DICKSON, and A. G. JOHNSON (*U.S. Dept. Agr., Tech. Bul.* 341 (1933), pp. 40).—Certain phases of the nature of stripe disease of barley caused by *Helminthosporium gramineum*, the effect of environmental conditions on its development, and its control by seed treatment were studied in cooperation with the Wisconsin Experiment Station.

Kernels of healthy heads become inoculated by spores blown from nearby diseased plants. Natural inoculation of kernels in the field by wind-borne spores may occur for some time after flowering. While under some conditions spores on the outside of the seed may produce infection in the seedling, dormant mycelium between the glume and the seed pericarp is considered the principal means of the fungus living over from one crop to another.

Removing the glumes from naturally inoculated kernels before sowing had no effect on the percentage of stripe-diseased plants. Spores from dried barley leaves kept in the laboratory at Arlington, Va., did not germinate after 4 months. The longevity of the conidia seems to depend upon conditions of temperature and humidity during storage. Dormant mycelium in the seed was observed to remain viable for at least five years.

Increased soil fertility or other conditions favoring vigorous plant growth, according to observations, apparently decreases the percentage of diseased

plants from naturally inoculated seed. Growing temperatures of 15° C. (59° F.) or lower and relatively dry soil from planting to emergence favored the development of the disease in plants from naturally inoculated seed, while it was inhibited by high soil temperatures and very wet soil during this period.

In stripe-disease control experiments during the period 1926-30, tests of more than 75 fungicidal dusts showed the effectiveness of the dust fungicides used to be independent of soil reaction and, in general, of soil moisture. Relatively dry soil during emergence reduced the effectiveness of many of the seed treatments. Although the ordinary wet formaldehyde treatment controls stripe disease satisfactorily, formaldehyde dusts were found ineffective.

Observations on *Rhynchosporium secalis* (Oud.) Davis, leaf blotch of barley and rye, F. T. BROOKS (*New Phytol.*, 27 (1928), No. 4, pp. 215-219, pl. 1, figs. 3).—Barley and rye leaf blotch (*R. secalis*) is said to be common near Cambridge, England, chiefly in late winter and early spring. It also attacks wild grasses.

It is stated that even the most susceptible types of barley grow away from the fungus in the spring so as rarely to present infection of the later formed leaves.

The peculiar method of spore formation in *R. secalis* on the host is described. Inoculation experiments show that both leaf surfaces may be infected without causing injury.

Origin of physiologic forms of *Puccinia graminis* through hybridization and mutation, E. C. STAKMAN, M. N. LEVINE, and R. U. COTTER (*Sci. Agr.*, 10 (1930), No. 11, pp. 707-720).—To test the view that physiologic forms and varieties of the cereal rusts arise through hybridization, reciprocal crosses were made between *P. graminis tritici* and *P. graminis secalis* and between *P. graminis tritici* and *P. graminis agrostidis*. From a single aecial cup resulting from the intermixing pycnial nectar of *tritici* × *agrostidis*, eight physiologic forms of *P. graminis tritici* were isolated, some of these not having been identified previously. Two forms resulting from *secalis* × *tritici* crosses proved less virulent on the differential wheat varieties than the *tritici* parent, though one of them inherited from its *secalis* parent the ability to infect slightly the rye differentials. In a uredinial culture of *P. graminis tritici* form 1, collected in 1915 and constant pathogenically for over 13 years, four forms of *P. graminis tritici* appeared successively, two of which were unknown previously. The mutants are said to have been consistent pathogenically during several uredinial generations on the wheat differentials.

"These results, and those of other investigators, indicate that varieties and physiologic forms of *P. graminis* may be considered as dikaryotic clones that remain constant in the uredinial stage, except for mutation. They may, however, lose their identity in passing through the barberry because of segregation in the promycelia of the teliospores, or because of the initiation of a new dikaryophase in the pycnia or aecia. Because of the fact, therefore, that the barberry may be the breeding ground for new and possibly dangerous forms of stem rust, the results from a practical standpoint constitute an additional argument for barberry eradication."

A preliminary study on the hybridization of physiologic forms of *Puccinia graminis tritici*, M. NEWTON, T. JOHNSON, and A. M. BROWN (*Sci. Agr.*, 10 (1930), No. 11, pp. 721-731, figs. 4).—When crosses were made between physiologic forms of wheat rust, *P. graminis tritici*, the hybrid forms were different from the parental forms in all cases but one, some being new, some identical with previously known forms. By selfing it was discovered that most forms were heterozygous. At least one, form 9, was homozygous. In 95 percent

of the aecia studied, not more than one physiologic form was obtained from each individual aecium.

A study of the inheritance of spore colour and pathogenicity in crosses between physiologic forms of *Puccinia graminis tritici*, M. NEWTON, T. JOHNSON, and A. M. BROWN (*Sci. Agr.*, 10 (1930), No. 12, pp. 775-798, figs. 8).—As a result of a study which has been made on the inheritance of color and the pathogenicity characters in crosses between physiologic forms of *P. graminis tritici* of abnormal color described as arising in work previously noted (E.S.R., 61, p. 237), it is stated that there appears to be an association between color and pathogenicity in some forms of the second generations of the crosses 36 (grayish-brown) × 9a (orange) and 9 (red) × 15 (red).

Observations and researches on resistance to rust of the higher internodes in wheat [trans. title], A. DRAGHETTI (*Ann. R. Staz. Sper. Agr. Modena, n. ser.*, 1 (1927-1929), pp. 69-121, pls. 3).—This gives mainly the details of a study of rust resistance under different conditions in the upper parts of different wheat varieties derived largely as the result of hybridization. Compactness of head and length of host internode were among the several features tested in connection with susceptibility to smut. The results are largely tabulated, with discussion.

Relation of weather to the prevalence of wheat stem rust in Nebraska, G. L. PELTIER (*Jour. Agr. Res. [U.S.]*, 46 (1933), No. 1, pp. 59-73).—Study at the Nebraska Experiment Station of the time and length of the fruiting period of wheat in the period 1903-1930 showed that epidemics of stem rust (*Puccinia graminis tritici*) (E.S.R., 58, p. 44) did not occur in eastern Nebraska when winter wheat headed before or during the first week in June and ripened before July 1. These years might be classed as rust escaping. While rust epidemics occurred during occasional years within the period they were not always correlated with an extended fruiting period, since during other years with fruiting periods of the same length little or no rust developed.

Intensive studies from 1921 to 1930 of several factors influencing the development of stem rust led to the conclusion that a rust epidemic is possible in the winter wheat area of Nebraska only when a certain combination of factors is present in sequence. These factors comprise a large amount of initial inoculum, reaching the State when conditions favor maximum infection, and the subsequent production of large numbers of primary uredia over a large area; winter wheat entering the heading stage June 1 to 7, or thereafter, with primary uredia appearing at about the same time; and an extended fruiting period, during which optimum temperature, an evenly distributed precipitation above the normal, and other favorable conditions are present for the rapid development of urediosporic generations. Low temperatures appear to be the major limiting factor in the development of primary infection and subsequent development of uredia, whereas lack of an even distribution of sufficient precipitation is the major inhibiting factor in the development of subsequent urediosporic generations during most years. The sequence of factors necessary for stem rust epidemics is fulfilled only in occasional years in the winter wheat areas of Nebraska.

Some new or unusual disease developments on wheat in Kansas, C. O. JOHNSTON (*Kans. Acad. Sci. Trans.*, 33 (1930), pp. 31-40).—As a result of rank growth in wheat in 1929 owing to abnormal weather conditions described, scab (*Gibberella saubinetii*), leaf blotch (*Septoria tritici*), and black chaff (*Bacterium translucens undulosum*), hitherto regarded as minor diseases of wheat, and crinkle joint (cause unknown, relatively new in Kansas) figured prominently, causing considerable losses. The reactions of various wheats to leaf blotch are tabulated.

Penetration of *Fusarium vasinfectum aegyptiacum* into roots of cotton [trans. title], T. FAEMY (*Bul. Soc. Bot. Genève*, 2. ser., 22 (1930), pp. 62-125, pls. 3, figs. 25).—This paper gives a condensed history of the development of cotton culture in Egypt, and a brief account of work done on wilt (*F. vasinfectum aegyptiacum*) during the period from 1882 to 1926. The disease is compared with sore shin, dealt with by Britton-Jones in 1922 (*E.S.R.*, 55, p. 345), and the growth of the wilt fungus in media containing nitrogen in the form of calcium nitrate is compared with that in media containing ammonium chloride in the presence of different carbohydrates.

Ascochyta disease of flax [trans. title], H. DIDDENS (*Tijdschr. Plantenziekten*, 35 (1929), No. 9, pp. 251-253).—Late in May 1928 yellow, stunted flax plants were found mingled with sound and vigorously growing young plants. The trouble was determined as a foot and bast rot associated with *A. linicola*.

Cardinal temperatures of pea-wilt fusaria in culture, K. TOGASHI (*Japan. Jour. Bot.*, 5 (1931), No. 4, pp. 385-400, fig. 1).—Following up the accounts previously noted (*E.S.R.*, 67, p. 269), the author now describes in summary detail the temperature relations of the *Fusariums* in cultures, estimating the cardinal points for optima of mycelial growth and sporulation.

"As seen in most fungi the temperature limits for the sporulation of the fusaria studied were narrower than those for the mycelial growth."

Diseases of peas in Arizona, J. G. BROWN and M. M. EVANS (*Arizona Sta. Bul.* 142 (1933), pp. 41-78, figs. 16).—This is a presentation of general information on the symptoms, causes, and control of various parasitic diseases, including powdery mildew, downy mildew, *Fusarium* foot rot, *Rhizoctonia* root rot, Texas root rot, bacterial blight, and nematodes and certain physiological troubles resulting from drought, alkali, and hail.

Investigations concerning the plant and tuber rot of potato and its control [trans. title], R. SCHANDER and G. STAAR (*Arb. Kartoffelbaugesell.*, No. 33 (1930), pp. 138, pls. 2, figs. 14).—This account deals in systematic detail with potato blight (*Phytophthora infestans*), as regards the plant, the disease, and the remedial measures including the methods of their application.

The blue discoloration of potatoes [trans. title], H. L. G. DE BRUYN (*Tijdschr. Plantenziekten*, 35 (1929), No. 7, pp. 185-222, pls. 2; *Eng. abs.*, pp. 216-220).—The blue discoloration of potato tubers which causes in some years considerable damage, presumably the same phenomenon as that described under the name bruise by Horne (*E.S.R.*, 28, p. 648), is here described in detail, with reference to later views regarding the nature of the trouble.

One cause frequently met with is mechanical injury. A causal or conditioning relation was supposedly established between the specific gravity of the tuber and this change or susceptibility thereto. The stem end of the tuber, which is the more susceptible area to bruise, has also the highest specific gravity. In case of Roode Star, the lowest specific gravity was attained when low or lacking in nitrogen but with potassium present; only the tubers having the highest specific gravity were susceptible, but the general influence of manuring is not quite clear. On certain soils dark spots were observable externally in many tubers, particularly those especially liable to strong blue discoloration. These spots were mostly at the stem end, sometimes as far as halfway down the tuber but never at the distal end. These spots increase in size and number for some months after digging. Internally they appear to be necrotic regions situated ± 1 mm from the skin and parallel thereto. References are given to this condition as noted by other authors.

The number of the spots is augmented by nitrogen and lessened by potash manuring. Diseased tubers if carefully handled appear normal. The gradual

increase in the size and number of the spots suggests an organism as the cause, but no proof of this is yet evident. Tuber-grafting tests for virus proved negative.

Experimental studies on the possibility of primary infection of *Piricularia oryzae* and *Ophiobolus miyabeanus* internal of rice seeds [trans. title], H. SUZUKI (*Ann. Phytopath. Soc. Japan*, 2 (1930), No. 3, pp. 245-275, pl. 1, fig. 1; *Eng. abs.*, pp. 274, 275).—Rice seeds infected by *P. oryzae* or *O. miyabeanus* (*Helminthosporium oryzae*) show usually a small or large discoloration, sometimes only a shrivelling effect. Absence of external symptoms does not insure soundness, as internal parasites in healthy-looking plants have been demonstrated by microscopy as well as by isolation experiments.

The method of selection for healthy rice seeds by the use of a salt water solution (sp. gr. 1.1) seems to be inapplicable.

P. oryzae and *O. miyabeanus* appear able to infect rice (so as to show in the seeds) at any period before or after blooming. These fungi appear able to infect the young seedlings soon after germination in the spring.

Rice seeds may harbor these fungi in a viable state, *P. oryzae* for at least two years and *O. miyabeanus* for four years, under certain indicated conditions. Viability is destroyed after five minutes in *P. oryzae* kept in water at 50° C., in *O. miyabeanus* at 55°.

On the influence of copper sulfate to the growth of *Piricularia oryzae*, with special reference to the temperature as an environmental factor [trans. title], T. ABE (*Ann. Phytopath. Soc. Japan*, 2 (1930), No. 3, pp. 171-196, figs. 11; *Eng. abs.*, pp. 195, 196).—Testing first the relation of temperature to the growth of the strain of *P. oryzae* to be used, the author found that on potato decoction agar containing 1 percent of sucrose the most vigorous mycelial growth occurred at a temperature near 28° C., this vigor lessening gradually for temperatures about 24°, 20°, 11°, and 36°.

At about 28°, the most favorable temperature, mycelial growth was stimulated by adding copper sulfate in concentrations between $\frac{1}{6000}$ and $\frac{1}{400}$ M, the maximum stimulation occurring around $\frac{1}{4000}$ M. In liquid medium also a stimulating action of copper sulfate was noticeable, but this was not so great as in the case of the agar medium.

At 20°, 24°, and 32° no stimulating action of the copper sulfate was noticeable. At about 36° no conclusive results were obtained either in the liquid or on the agar. At any temperatures employed, conidia formed in inverse proportion to the copper sulfate present, when this was above $\frac{1}{6000}$ M, the formation becoming almost nil when $\frac{1}{400}$ M was reached.

On the culture media having copper sulfate in concentrations higher than $\frac{1}{600}$ M, chlamydospores formed at all the temperatures tested. In contrast to the tendency observed in conidial formation, the limitation of chlamydospore formation in relation to copper sulfate concentration lowered in proportion to the temperature departure from the optimum for mycelial growth.

The development of the aerial mycelium decreased with the concentration of copper sulfate, being absent at $\frac{1}{200}$ M for all temperatures.

Coloration and attenuation changes are detailed for certain concentration ranges.

Comparative studies of *Bacterium sesami* with *B. solanacearum* and *B. sesamicola* [trans. title], K. NAKATA (*Ann. Phytopath. Soc. Japan*, 2 (1930), No. 3, pp. 222-243, pl. 1; *Eng. abs.*, pp. 242, 243).—A comparative study was made of the morphology, cultural characters, and physiology of these three forms, recorded as causing sesame diseases.

The author inclines to consider *B. sesami* as identical with *B. sesamicola* (synonymous with *Pseudomonas sesami*) and as distinguished from *B. solanacearum*. A description is recorded.

The physiology and variations of *Cercospora beticola* in pure culture, G. H. COONS and F. G. LARMER (*Mich. Acad. Sci., Arts, and Letters, Papers, 11 (1929), pp. 75-104, pls. 3*).—Sugar beet leaf spot is caused by *C. beticola*. This organism grows well on most of the standard culture media. Though light supposedly affects its development but little, temperature materially affects the vegetative growth. Conidial production in artificial cultures has been found to be a response to a nutrient stimulus, light and temperature influences being flexible.

Zonation in cultures is due to the differential growth of mycelium and not to conidial production. It can be induced by alternating conditions of light and temperature, other factors influencing but not initiating zonation.

Variant forms appearing as wedge-shaped sectors isolated from single-spore cultures of *C. beticola* have proved constant on artificial media. Though passage of the aberrant forms through sugar beets has measurably restored the normal color, this has only partially changed some morphological characters.

Attempts to produce variations by wounding, exposure to gas, low temperatures, or chemicals have failed. Mixing a normal mycelium with a variant culture gave a sectoring pattern resembling the normally occurring type and indicating the mechanics of sector formation.

The behavior of these variant forms indicates that they should be regarded as modified forms having their development determined partly by nutritional disturbances.

Relative resistance to mosaic of native and imported sugarcane varieties [trans. title], P. R. KUNTZ (*Puerto Rico Dept. Agr. and Com. Sta. Circ. 101 (1932), Spanish ed., pp. 23, figs. 6*).—Comparative studies of 26 popular varieties and new canes, made in cooperation with a central at Manati, showed the percentages of infection with mosaic to range from 0 in P.R. 803, P.R. 807, M. 7, and M. 42 to 19 in B.H. 10 (12). P.O.J. 2727 had 1 percent; Co. 281, 1.3; F.C. 998, 2; P.O.J. 2725, 2.3; F.C. 916, 2.5; P.O.J. 2714 and P.O.J. 2878, 3; Badilla, 7; Caledonia Amarilla, 11.7; P.R. 826, 12.3; S.C. 12 (4), 14; D. 433, 16; and F.C. 966, 18.7 percent. The new and the more popular canes are grouped according to their relative susceptibility. The zones of infection in 1931 and 1932 are shown on outline maps, and the areas of important varieties are indicated for the 1927-28 and the 1931-32 crops.

Downy mildew of tobacco, E. E. CLAYTON and J. G. GAINES (*U.S. Dept. Agr. Circ. 263 (1933), pp. 8, figs. 3*).—Downy mildew or blue mold of tobacco is described, and the life history of the causative organism (*Peronospora hyoscyami*) is traced. This is primarily a seed bed disease, although it occasionally attacks plants in the field. Control methods include the sowing of an increased number of plant beds by growers so that some at least escape severe damage or entirely, and transplanting as rapidly as plants become large enough in mildew-free beds, or in infected beds delaying transplanting until the attack subsides and plants recover.

A program is suggested for those who desire to try spraying. Bordeaux mixture appears to be about as effective as any other spray or dust, and either a 3-4.5-50 or a 4-6-50 formula may be used. Applying the spray regularly every seven days and starting as soon as the plants are 0.25 in. across are suggested. These treatments may also assist in the control of certain other leaf spot and plant bed troubles. Spraying should be stopped a week before

transplanting, however, as there is evidence that plants heavily sprayed just before they are set out may not live as well as those not sprayed.

Comparative serological and pathological investigations of the fire-blight organism and a pathogenic fluorescent group of bacteria. H. R. ROSEN and W. L. BLEECKER (*Jour. Agr. Res. [U.S.]*, 46 (1933), No. 2, pp. 95-119, pl. 1, figs. 5).—This paper is devoted largely to the details and results of serological studies at the Arkansas Experiment Station of a fluorescent bacterial pathogen found in isolations from blighted unopened pear and apple blossoms and here designated as pear and apple blast. On the one hand the pathogen showed numerous cultural and physiological reactions identical with those of the fire blight organism (*Erwinia amylovora*) and on the other presented characteristics which have been attributed to various fluorescent plant pathogens. Comparisons were made with isolates of *E. amylovora* and *Phytophthora syringae*, *P. citriputeale*, and *P. prunicola* with respect to physiology, cultural characteristics, morphology pathogenicity, and serology.

The lilac blight organism (*P. syringae*), the English plum wilt pathogen (*P. prunicola*), and the newly identified pear blast isolates produced indistinguishable symptoms on pear twigs and leaves, the symptoms being obtainable with or without wounds. The pear blast isolates *P. syringae* and *P. prunicola* produced symptoms on oranges and lemons that were indistinguishable from those produced by the citrus blast pathogen *P. citriputeale*. *E. amylovora* isolates, on the other hand, produced no infections on orange and lemon.

The results of the serological tests were in full agreement with those of the pathogenicity studies. *P. syringae*, *P. citriputeale*, and *P. prunicola* and pear blast isolates were so closely related, as shown in cross agglutination tests, as to be indistinguishable. The close correlation shown between pathogenicity and serological reactions is believed indicative of the value of the latter in determining relationships of bacterial plant pathogens.

Studies on a new canker disease of Japanese pear trees caused by *Phomopsis fukushii* n. sp., S. TANAKA and S. ENDO (*Tottori Nōgaku-Kwaishō* (Trans. Tottori Soc. Agr. Sci.), 2 (1930), No. 1, pp. 123-134, pls. 2).—An account is given of studies on a new canker of Japanese pear trees (*Pyrus serotina*), said to have been first noticed by T. Fukushi in 1924 and studied after 1925 by the present authors. The disease is known to be prevalent in Tottori, Kanagawa, and Saitama Prefectures. The causal fungus (*P. fukushii*) invades cut ends of branches and wounds on trunks and limbs, causing dark brown cankers. The pear varieties Okusankichi, Nijisseiki, and Taihei are more or less resistant, while Imamura-aki, Imamura-natsu, Chōjūrō, and Meigetsu are susceptible.

On artificial inoculation, the fungus attacks not only the Japanese pear trees but also European pear trees (*P. communis*). Apple trees are immune. The temperature range for the mycelial growth of the fungus is about 8° to 33° C.

Comparisons of new and old materials for scab control. W. C. DUTTON (*Michigan Sta. Quart. Bul.*, 15 (1933), No. 3, pp. 178-181, fig. 1).—Severe scab conditions in 1932 permitted a thorough test of 17 different protective materials. No material gave complete control, but certain kinds, including lime-sulfur (2.5-100), gave satisfactory results, even on the highly susceptible McIntosh variety. With Jonathan all materials gave fair or better results, ranging from 30.6 to 95.7 percent of scab-free fruits, with the control 100 percent scabby. The need of thorough and timely treatment is stressed.

Spoilage of stone fruits on the market. C. BROOKS (*U.S. Dept. Agr. Circ.* 253 (1933), pp. 12, figs. 6).—Citing data procured by the Bureau of Agricul-

tural Economics on decay losses in peaches in transit, the author points out the correlation between shipping losses in Georgia peaches traceable to brown rot and the rainfall occurring during the growing period. On the other hand the occurrence of *Rhizopus* rot during transit was determined almost entirely by picking, packing, and shipping conditions and not by rainfall. With cherries, peaches, and plums, sound fruit from unsprayed trees developed approximately four times as much brown rot in transit as did sound fruit from sprayed or dusted trees. The development of brown rot was greatly stimulated by injuries such as those caused in careless handling.

Observing a much higher percentage of both brown rot and *Rhizopus* in the upper crates within a car, temperature studies were conducted within experimental cars which showed that in a trip lasting from 3.5 to 4.5 days the temperature in the top of the load averaged about 12.5° F. higher than at the bottom. The period required for the top fruit to lower to 50° was approximately five times that of the lower fruits. Four methods of reducing spoilage, namely, precooling, use of car blowers, addition of salt to ice, and addition of dry ice to the ice, are discussed.

A test with potassium sulfate against leaf marginal disease of red currant [trans. title], T. A. C. SCHÖFFERS (*Trijdschr. Plantenziekten*, 35 (1929), No. 8, pp. 231-233, pls. 2).—In recent years a leaf margin disease has been coming increasingly into notice, particularly in case of currant and apple. The phenomenon appears to depend rather upon conditions within the plant than upon those in the leaf areas affected. It becomes noticeable in mid-summer (July), and later it becomes very striking, as the leaves show check in growth, deepening marginal discoloration, curling, and eventual dryness. The trouble is contrasted with the so-called die-back attributed to the presence of a *Botrytis*. A soil relation is thought to be causal in the present case, and the increased use of potassium sulfate is regarded with favor.

A new species of Urocystis on Convallaria majalis L., K. TOGASHI and F. ONUMA (*Japan. Jour. Bot.*, 5 (1930), No. 1, pp. 21-26, fig. 1).—A disease (supposedly new) of *C. majalis*, noted halfway up Mount Himekami in the Province of Rikuchu, yellowing and stunting the plants, was associated with a fungus supposed to be a new member of *Urocystis*. A technical description has been furnished to accompany the name applied to the fungus, *U. miyabeana*.

A serious case of dwarfing and malformation of narcissus (Soleil d'Or), D. H. JONES (*Sci. Agr.*, 10 (1930), No. 11, pp. 750-753, figs. 3).—In case of a planting of 140,000 Soleil d'Or narcissus bulbs (1929-30), about 50 percent of the flowers produced were unfit for sale on account of dwarfing, malformation, and brown spot discoloration of the stems and foliage. No fungus or bacteria could be found, and the disease was not noticeably progressive, but the lesions appeared characteristic of those caused by *Tylenchus dipsaci*. None of the nematodes were present, but it is thought probable that the bulbs producing the diseased plants had been infested with *T. dipsaci* while growing in the field and that after being harvested the bulbs had been treated to destroy the nematodes. The injury done to the bulbs by the nematode's previous to their destruction is deemed responsible for the abnormal appearance of the flower stalks and leaves and for the brown markings and decayed areas inside the bulbs.

The bulb- or stem-nematode (*Tylenchus dipsaci* Kühn) as a pest of phlox, G. STEINER and B. O. DODGE (*Jour. N.Y. Bot. Gard.*, 30 (1929), No. 356, pp. 177-184, figs. 4).—Phlox disease due to *T. dipsaci* is said to have been observed in the United States as early as 1923. A description of the diseased plants is given, with accounts of observations on areas affected by the nematode.

Recommendation as to control emphasizes complete removal and burning of diseased plants and infested soil.

Angular leaf spot of *Zinnia elegans* Jacq. caused by eelworms (preliminary report), T. FUKUSHI and H. SAITO (*Tottori Nōgaku-Kwaishō (Trans. Tottori Soc. Agr. Sci.)*, 2 (1930), No. 1, pp. 45-56, pl. 1).—In this preliminary report a new angular leaf spot disease of *Z. elegans* is described as noted at Nagi-Mura in 1928. It is said to be of abundant occurrence locally in the province of Inaba, Japan. It is due to attack by a nematode, *Aphelenchus ritzema-boschii*, which it is stated also readily attacks *Phlox drummondii* and *Dahlia variabilis* in foreign countries. When artificially inoculated, it attacks healthy leaves of zinnia and dahlia and multiplies in the diseased tissues. The results of inoculation experiments on chrysanthemum leaves were inconclusive, though a few naturally infested chrysanthemums were found growing near the affected zinnia plants.

The elm disease and the elm bark beetle [trans. title], J. G. BETREM (*Tijdschr. Plantenziekten*, 35 (1929), No. 11, pp. 273-288, pls. 3; *Ger. abs.*, pp. 284, 285).—It is shown in this account of experimentation that *Scolytus scolytus* can transmit *Graphium ulmi*, thus infecting the wounds which it has made with the Dutch elm disease.

On the life history of *Uredinopsis pteridis*, with a special bearing on its peridermal stage [trans. title], S. KAMEI (*Ann. Phytopath. Soc. Japan*, 2 (1930), No. 3, pp. 207-228, pl. 1; *Eng. abs.*, pp. 226-228).—In contrast to the views resulting from the findings of Weir and Hubert (*E.S.R.*, 38, p. 553), to the effect that the teliospores of *U. pteridis* seem to have the power of germinating as soon as they are ripe (without hibernation) and that the needles of *Abies* become infected in the late summer or fall, theaecia appearing early the next spring, the present author states that the teliospores of *U. pteridis* on *Pteridium aquilinum japonicum* collected near Sapporo were proved to germinate in the spring after having overwintered and to infect *A. mayriana* when the needles were still young, the peridermal stage germinating about a month after the inoculation. The author questions, for reasons detailed, the finality of the claims above referred to.

ECONOMIC ZOOLOGY—ENTOMOLOGY

The musk rat in Germany (*Jour. Min. Agr. [Gt. Brit.]*, 39 (1932), No. 8, pp. 719-724).—This is an account of the North American muskrat, a few pairs of which were released in central Europe in 1905. It has multiplied so rapidly and done such extensive damage that the German Government has had to take active steps to keep it in check. It infests streams, canals, ponds, and ditches, and does great damage by burrowing in the banks and by building obstructions in the beds of streams. It also causes damage to agricultural crops, freshwater fish, and mollusks, and may attack small livestock.

Notes on the giant toad, *Bufo marinus* (L.), in Puerto Rico, M. D. LEONARD (*Jour. Econ. Ent.*, 26 (1933), No. 1, pp. 67-72).—This contribution from the Puerto Rico Insular Experiment Station reports upon the distribution, life history, and habits, so far as known, of the giant toad (*B. marinus*), together with a summary of a study of its food habits which indicates that it consumes large quantities of injurious insects. It is pointed out that live toads have been shipped to Hawaii and become established.

Justifying expenditures for entomological research, J. J. DAVIS (*Jour. Econ. Ent.*, 26 (1933), No. 1, pp. 72-79).—In this contribution from the Indiana Experiment Station information is presented which shows large returns to

have resulted from the expenditure of Federal and State funds for entomological research.

A method of determining losses to forests caused by defoliation, J. N. SUMMERS and A. F. BURGESS (*Jour. Econ. Ent.*, 26 (1933), No. 1, pp. 51-54).—A brief discussion of the problem is presented in connection with formulas that have been developed, based upon June and July defoliation in New England.

Some examples of varietal resistance of plants to insect attacks, G. F. MACLEOD (*Jour. Econ. Ent.*, 26 (1933), No. 1, pp. 62-67, figs. 3).—The author has found sweet Spanish varieties of onions to be resistant to the onion thrips and green celery varieties resistant to injury by the tarnished plant bug.

Shipping adult insect parasites in refrigerated containers, J. K. HOLLOWAY (*Jour. Econ. Ent.*, 26 (1933), No. 1, pp. 280-282, pl. 1).—The author reports that "a refrigerated container devised to decrease the mortality in shipments of parasites has been used successfully in transporting frail adult stages of several species of parasites of the oriental fruit moth (*Grapholitha molesta* Busck) to practically all of the peach-growing centers in the eastern part of the United States. The shipments were made throughout the entire summer of 1931. The average consignment was in transit 50 hours, and the average mortality of *M[acrocentrus] ancylovorus* Roh. shipped under such conditions was only 1.4 percent."

[Work with economic insects, etc., in California] (*California Sta. Rpt. 1932*, pp. 30, 58-65).—Reference is made to the progress of (E.S.R., 67, p. 559) beekeeping investigations, including studies of low diastase content of honeys caused by low pollen content and of losses of bees from buckeye poisoning; work with insect parasites and predators of the peach twig moth and other pests; use of insecticides for control of red scale, latania scale, and walnut husk fly; oil sprays and tank mixture methods (E.S.R., 67, p. 563); miscellaneous chemical sprays, including sodium nitrate for mealy plum aphid; dusts; soil fumigants; irrigation and flooding in the control of pear thrips; control of the vegetable weevil; and nematodes, slugs, and snails.

[Report of work in entomology in Delaware] (*Delaware Sta. Bul. 179 (1932)*, pp. 29-37).—In this report (E.S.R., 66, p. 550) the important insects of the year are dealt with by L. A. Stearns; the mosquito survey and bionomics and control of the codling moth and the oriental fruit moth by Stearns and D. McCreary; and bionomics and control of the grape leafhopper, the plum curculio, and the grape berry moth by Stearns, L. L. Williams, and McCreary.

[Report of work in entomology in Indiana] (*Indiana Sta. Rpt. 1932*, pp. 34-38, figs. 3).—Brief reference is made to the work of the year with insects (E.S.R., 67, p. 560), including the onion maggot, cucumber beetles, cabbage worm, potato leafhopper, the mint flea beetle, European corn borer, codling moth, and oriental fruit moth.

[Report of work in entomology in Iowa] (*Iowa Sta. Rut. 1932*, pp. 54-60, figs. 2).—Progress during the year in entomology (E.S.R., 67, p. 424) is briefly noted under the headings of white grub investigation, by C. J. Drake and E. V. Collins; time and labor factors involved in gathering, ripening, and storing of honey by honeybees, by O. W. Park; bionomics and control of the apple maggot (*Rhagoletis pomonella* Walsh), by C. H. Richardson; Hessian fly survey, cornstalk borers (*Papaipema nebris* Guen., *Luperina stipata* Morr., etc.), and biology and control of onion insects, particularly as vectors in the yellow dwarf disease, all by Drake; quantity of bait eaten by grasshoppers and effect of carbohydrates on longevity of the apple maggot fly, both by Richardson; stock replacement in honeybees and studies on the races of bees, both by

Park; survey of potato insects, by Drake; and a study of egg deposition, poisons, attractants, and parasites of injurious grasshoppers in Iowa (differential, two-striped, and red-legged grasshoppers and *Melanoplus mexicanus* Sauss.), by Drake and Richardson.

[Report of work in entomology and limnology by the New York Cornell Station] (*New York Cornell Sta. Rpt. 1932, pp. 116-126*).—The work of the year (E.S.R., 66, p. 647) is briefly reported upon as to insecticides for control of the striped and spotted cucumber beetles and of insects attacking potatoes on Long Island; wireworms and their relation to pitting of potatoes; onion maggot control; tests of naphthalene in the prevention of injury to carrots and celery from the carrot rust fly; control of the tarnished plant bug; potato spraying experiments on muck lands; millipedes and scab gnats in their relation to potato tuber defects; effects of radiant energy on insects; utilization of carbohydrates and proteins by the onion thrips; honey color; wild insects in apple orchards; the flight of honeybees from different kinds of colonies; weevil fumigation with ethylene oxide; biology and control of the webbing clothes moth; control of dermestid larvae injurious in dwelling houses; the columbine borer and gladiolus thrips; transmission of the abortion organism, *Brucella abortus*, by fecal feeding flies; relation of water temperature to food consumption in trout; the relation of weight to length in various races of trout reared on nature; and on artificial foods; base bass cultural investigations; and cause of curdled milk in rainbow trout.

[Report of work in entomology in Ohio] (*Ohio Sta. Bul. 516 (1933), pp. 46-54, fig. 1*).—The work of the year (E.S.R., 67, p. 50) is referred to under the headings of codling moth, including its biology and use of treated bands as a supplementary codling moth control by C. R. Cutright; wireworms, by H. L. Gui; the onion maggot, by J. P. Slesman; the European corn borer, by L. L. Huber, J. B. Polivka, E. G. Kelsheimer, and J. R. Savage; the gladiolus thrips (*Taeniothrips gladioli* M. & S.), by E. A. Herr; the oriental fruit moth, by R. B. Neiswander and M. A. Vogel; and control of the small brown ant in golf greens, *Lasius niger neoniger* Emery, by C. R. Neiswander.

[Contributions on economic entomology] (*Jour. Dept. Agr. Puerto Rico 16 (1932), No. 2, pp. 81-144, pls. 3, figs. 9*).—The contributions presented include the following: Descriptions of New Mymarid Egg Parasites from Haiti and Puerto Rico (pp. 81-91), Notes on the Genus *Aneristus* Howard, with Descriptions of New Species [*A. mangiferae*, *A. hispaniolae*, and *A. asterole canii*] (Hymenoptera: Chalcidoidea) (pp. 93-102), and Two Important West Indian Seed Infesting Chalcid Wasps [*Tanaostigma haematowyli* n.sp. and *Bephrata cubensis* Ashm.] (pp. 103-112), all by H. L. Dozier; Three Species of *Empoasca* Leafhoppers Known to Affect Economic Plants in Haiti, Including the Description of Two New Species (*E. fabalis* DeL., *E. gossypii* n.sp., and *E. ocanavalia* n.sp.), by D. M. DeLong (pp. 113-116); A New Citrus Cambium Miner (*Asynapta citrinae* n.sp.) from Puerto Rico, by E. P. Felt (pp. 117, 118); A New Neotropical Genus of Eupteryginae (Homoptera) from Puerto Rico [*Hybla maculata* n.sp.], by W. L. McAtee (pp. 119, 120); and Insect Conditions in Puerto Rico during the Fiscal Year, July 1, 1930, through June 30, 1931, by M. D. Leonard (pp. 121-144).

[Contributions on economic insects] (*Jour. Southeast. Agr. Col., Wye, Kent, No. 28 (1931), pp. 137-187, figs. 18; 211-215*).—The contributions presented include the following: Some Observations on Winter Moth Caterpillar [*Cheimatobia brumata*] Attack on Fruit Trees in 1929-30 (pp. 137-146) and A Note on the Strawberry and Raspberry Bud Weevil, *Anthonomus rubi* (Herbst) (pp. 147-152), both by S. G. Jary; A Contribution to the Biology

of the Apple Capsid (*Plesiocoris rugicollis* Fall.) and the Common Green Capsid (*Lygus pabulinus* Linn.), by M. D. Austin (pp. 153-169); Observations on Gall Midges Affecting Fruit Trees (pp. 170-177) and Notes on the Outbreak of the Cabbage Aphid (*Brevicoryne brassicae* Linn.) in 1929 (pp. 178-180), both by F. H. Barnes; The Preparation of Oil Sprays—I, The Use of Oleic Acid as Emulsifier, by H. Martin (pp. 181-187); and Insect Visitors to Fruit Blossoms by C. H. Hooper (pp. 211-215).

[Notes on economic insects and insecticides] (*Jour. Econ. Ent.*, 26 (1933), No. 1, pp. 291-304, fig. 1).—The contributions presented (E.S.R., 68, p. 636) include the following: Propylene Dichloride as a Fumigating Material, by R. Hutson (p. 291); The Gladiolus Thrips, *Taeniothrips gladioli* M. and S., in California, by S. F. Bailey (pp. 291, 292); Arsenic in Balt-Poisoned Grasshoppers, by T. H. Hopper (p. 292); Parasites from a Bird's Nest, by W. E. Whitehead (pp. 292, 293); *Abia americana* (Cresson) on Lonicera, by H. H. Kelfer (p. 293); *Rhizopertha dominica* as a Library Pest, by W. A. Hoffman (pp. 293, 294); A Braconid Parasite [*Homotylus terminalis*] of a Coccinellid [*Cycloneda sanguinea* L.] New to Puerto Rico, by M. D. Leonard (p. 294); Control of an Infestation of the Cigarette Beetle in a Library by the Use of Heat, by A. W. Cressman (pp. 294, 295); The Flannel Moth [Megalopygidae] in Arizona, by W. W. Jones (pp. 295, 296); Coleoptera Captured in Japanese Beetle Traps, by F. W. Metzger and R. J. Sim (pp. 296, 297); A Note on the Hibernation Habits of Some Engraver Beetles of the Genus *Ips*, by F. P. Keen (pp. 297, 298); Notes on a Coccinellid (*Hyperaspis 8-notata* Casey) Predacious on Citricola Scale (*Coccus pseudomagnoliarum* Kuwana) in Tulare County, California, by F. T. Scott (pp. 298, 299); The Toxicity of the Common Castor-Bean Plant in Respect to the Japanese Beetle, by F. W. Metzger (pp. 299, 300); Outbreak of Grasshoppers [the American Grasshopper, Red-Legged Grasshopper, et al.] in Tennessee during 1932, by W. W. Stanley (pp. 300, 301); Why Not Bourgault's Trap for Horse-Flies? by B. Segal (pp. 301, 302); and Comparative Toxicities, with Special Reference to Arsenical and Fluorine-Containing Insecticides, by F. DeEds (pp. 302-304).

Review of United States patents relating to pest control, [January-March 1932], R. C. ROARK (*U.S. Dept. Agr., Bur. Chem. and Soils, Rev. U.S. Pat. Relat. Pest Control*, 5 (1932), Nos. 1, pp. 11; 2, pp. 12; 3, pp. 12).—This volume, complete in three numbers, is in continuation of those previously noted (E.S.R., 67, p. 150).

Oil spray recommendations, R. H. ROBINSON and L. CHILDS (*Oregon Sta. Circ.* 107 (1933), pp. 8).—Methods for the preparation of home-made emulsions and the tank-mix oil spray are outlined by the authors.

Winter spraying of orchards, with particular reference to the control of red mite and apple capsid bug, J. CARROLL and E. McMAHON (*[Irish Free State] Dept. Agr. Jour.*, 31 (1932), No. 2, pp. 190-198).—In continuation of earlier work (E.S.R., 65, p. 757), Sunoco and Winter Volck, both used alone and in combination with a tar distillate (Carbokrimp) and in making two proprietary combination oil and tar-distillate sprays, gave very good control of the red mite (*Oligonychus ulmi*), aphid, and apple sucker (*Plesiocoris rugicollis*).

Effect of lead arsenate insecticides on orange trees in Florida, R. L. MILLER, I. P. BASSETT, and W. W. YOTHERS (*U.S. Dept. Agr. Tech. Bul.* 350 (1933), pp. 20, figs. 8).—This is a report of work conducted with a view to determining the effect of arsenical bait sprays such as are used for eradication of the Mediterranean fruit fly on citrus trees and fruit.

"No noticeable effect on the fruit, tree, or undergrowth of a grapefruit tree was produced by 60 spray applications of 0.5 lb. each of lead arsenate in 7.5 gal. of water to the soil under the tree. The applications were made over a period of 1½ years, and at the end of that time there were 2,000 parts of arsenic trioxide per million in the first 2 in. of soil, while only a trace was present in the leaves. Likewise, there was no effect on the fruit, tree, or undergrowth of an orange tree after 14 applications of 0.5 lb. of lead arsenate each in 7.5 gal. of water, even though there were 700 parts of arsenic trioxide per million in the first 2 in. of soil. One year after the last application an analysis of the soil under the grapefruit tree was again made and 1,800 p.p.m. was found in the first 2 in. of soil, and even at that time the tree, fruit, and undergrowth were normal. . . .

"The solids of fruit juice were somewhat increased when as little as 0.008 mg of arsenic trioxide was present, but when more than this quantity was present the solids were decreased. In this case also, approximately the same quantity of arsenic that stimulated the catalase activity caused the solids in the juice to be increased. . . . When the trees were sprayed 17 times with 5 gal. per application a maximum of 0.16 mg of arsenic trioxide per liter of juice was found.

"Experiments made by the writers have demonstrated that the effect of arsenic is not systemic, only the sprayed part of a tree being affected. The effect of spraying with arsenicals is shown almost immediately and persists to a slight degree for about 18 months. After 2½ years, however, it has entirely disappeared."

The effect of different soaps on lead arsenate in spray mixtures, J. M. GINSBURG (*Jour. Agr. Res. [U.S.]*, 46 (1933), No. 2, pp. 179-182).—In work at the New Jersey Experiment Stations "apple trees were sprayed three times at 2-week intervals with mixtures consisting of lead arsenate, hydrated ferric oxide, and each of the following soaps: Commercial potash fish-oil soap, potassium oleate, and triethanolamine oleate. The spray containing fish-oil soap produced severe injury and caused about 30 percent leaf drop. The injury from the potassium oleate spray was limited to spots on the leaves and browning of the leaf edges. The injury from the triethanolamine oleate spray was very slight and did not appear until after the third application.

"Simultaneously with the field tests the action of the following soaps on lead arsenate was tested in the laboratory: Potash fish-oil soap, sodium oleate, potassium oleate, ammonium oleate, and triethanolamine oleate. The results indicate that soaps of strong bases form more soluble arsenic than soaps of weak bases. Of all the soaps tested, potash fish-oil soap produced the greatest quantity of soluble arsenic and triethanolamine oleate the least."

Extractive efficiency of kerosene on pyrethrum powders of varying fineness, H. H. RICHARDSON (*Jour. Econ. Ent.*, 26 (1933), No. 1, pp. 252-259, fig. 1).—"The extractive efficiency of kerosene on pyrethrum powders of varying degrees of fineness was tested by comparing the insecticidal efficiency of such extracts with standard extracts of pyrethrum containing 50, 75, and 100 percent of the active constituents. House flies were used in the insecticidal tests, and the time, in seconds, until 50 percent of the flies were paralyzed was used as the main criterion for determining insecticidal power. Mortality data were taken, but, as reported in a previous paper [*E.S.R.*, 64, p. 854], the percentage kill was not a sufficiently sensitive index to indicate small differences in the pyrethrin content of kerosene extracts.

"The efficiency of extraction on 12 to 15, 20, 30, and 45 mesh pyrethrum powders was about the same in each case; it is estimated that 80 percent

extraction of the active constituents was obtained. Extraction of 200-mesh pyrethrum powder was more efficient, however, giving approximately 90 percent of the active constituents. Apparently the achenes, or seeds, which contain a very large percentage of the active constituents, are not thoroughly crushed in powders varying from 12 to 45 mesh, whereas with 200-mesh powder the achenes are entirely broken up. This difference might account for the observed differences in the extractive efficiency of kerosene on these various grades of powder."

The toxicity of certain plant extracts to goldfish, II, J. R. SPIES (*Jour. Econ. Ent.*, 26 (1933), No. 1, pp. 285-288).—This second contribution (E.S.R., 67, p. 51) reports upon further determinations of the toxicity to goldfish of acetone extracts of certain reputedly poisonous plants. Preliminary determinations of the toxicity to insects of the most promising of these extracts have shown that a few of them may possess considerable insecticidal value.

The rotenone content of Malayan tuba root, C. D. V. GEORGI and G. L. TEUK (*Malayan Agr. Jour.*, 20 (1932), No. 10, pp. 498-507).—Analyses made of samples of tuba root drawn from commercial consignments have shown wide variations in the rotenone content. "As a result of the analyses of samples of roots from individual species, it appears that the variations are due to commercial consignments frequently consisting of roots from different species of *Derris* and also of varying age. As far as the results of analysis of individual species are concerned, the figures to date indicate that *D. elliptica*, tuba puteh, offers the best possibilities as a source of rotenone. The optimum conditions of cultivation and harvesting have yet to be determined. The roots of the other variety of *Derris* commonly occurring in Malaya, *D. malaccensis*, erect Sarawak, would appear to be lacking in rotenone."

A comparison of the effectiveness of sustained vacuum and dissipated vacuum in fumigation with hydrocyanic acid gas, S. E. CRUMB and F. S. CHAMBERLIN (*Jour. Econ. Ent.*, 26 (1933), No. 1, pp. 259-262).—Experimental fumigation of cigars with hydrocyanic acid gas for the destruction of the cigarette beetle shows that under the conditions of the experiments fumigation with sustained vacuum was more effective than fumigation with dissipated vacuum.

A consideration of "interval shooting" as practiced in citrus fumigation, H. L. CUPPLES (*Jour. Econ. Ent.*, 26 (1933), No. 1, pp. 262-269, figs. 6).—It has been found that, for the purpose of obtaining a maximum value of $\int C dt$ from a given quantity of fumigant, interval shooting apparently is less advantageous than the usual procedure of introducing the entire charge of fumigant at the beginning of the fumigation period.

Some methods used in testing cattle fly sprays, A. M. PEARSON, J. L. WILSON, and C. H. RICHARDSON (*Jour. Econ. Ent.*, 26 (1933), No. 1, pp. 269-274, fig. 1).—Contributing from the Iowa Experiment Station, the authors report that a method which consists essentially of making close observations on sprayed cows of previously determined susceptibility to stable flies gave much better results than the present methods of testing cattle fly sprays for repellent efficiency.

"Thirty-five selected cows were used in determining the relative efficiency of six fly sprays. The cows were scrubbed with soap and water, then staked individually in a pasture, being removed only for watering and milking. The normal fly susceptibility of each cow was obtained from the average of two counts of the number of flies present, made hourly from 7 a.m. till 3 p.m. for a period of 3 days. The cows were then placed in 7 groups of 5 each, the maximum difference in the number of flies per cow per count between the groups

being about two. The six spray materials were then assigned by chance to each of 6 groups of 5 cows; the remaining group served as the control. Each cow was sprayed at 6 a.m. daily for 4 consecutive days with 2 fluid oz. of spray material applied with an electric sprayer. The fly susceptibility of the sprayed and control cows was determined as before. The results show that close individual observations of a relatively few cows of known fly susceptibility give more consistent and dependable results than less accurate observations on a large number of cows. The population of stable flies on unsprayed dairy cattle increases from 7 a.m. till about midday, after which it tends to become stationary."

A preliminary list of food-plants of some Malayan insects, N. C. E. MILLER (*Straits Settlements and Fed. Malay States Dept. Agr. Bul. 38, Sup. (1932), pp. 54*).—This is a supplement to Bulletin 38 previously noted (E.S.R., 56, p. 857).

The insect visitors of fruit blossoms, C. H. HOOPER (*Jour. Roy. Soc. Arts, 81 (1932), No. 4177, pp. 86-101, pls. 2*).—A brief account is given of the insect visitors of fruit blossoms, including the hive bee, bumblebees, other melliferous bees, wasps, ants, sawflies, flies, beetles, butterflies, and moths.

Reliability of differences between data obtained in cotton insect investigations, J. C. GAINES (*Jour. Econ. Ent., 26 (1933), No. 1, pp. 274-279*).—In this contribution from the Texas Experiment Station a statistical comparison is made of methods used in taking cotton insect infestations and in obtaining data on the growth of cotton plants in experimental plots.

Preliminary report regarding investigations on combating caterpillar pests in the oil palm cultivation, I. H. GONGGRIJP (*Commun. Gen. Expt. Sta. Alg. Ver. Rubberplanters Oostkust Sumatra, Gen. Ser. No. 48 (1931), pp. 31, pls. 5, figs. 3*).—The increasingly severe attacks upon oil palms by slug caterpillars (*Setora nitens* and *Orthocraspeda trima*), with the resulting defoliation of the leaves to the veins, over areas covering from 80 to 100 ha, led to the work reported and the finding of an effective method of control, the details of which are presented.

Observations on shade tree insects, E. P. FELT (*Jour. Econ. Ent., 26 (1933), No. 1, pp. 45-51*).—The occurrence of shade-tree insects in the Northeastern States in 1931 is reported upon.

How to combat certain pests of the household, S. MARCOVITCH (*Tennessee Sta. Bul. 147 (1933), pp. 19, figs. 13*).—A practical summary of information as to the control of insect and other pests of the household.

Naphthalene for the control of the onion thrips, F. B. MAUGHAN (*Jour. Econ. Ent., 26 (1933), No. 1, pp. 143-147, fig. 1*).—The use of crude naphthalene as a control measure for onion thrips on onions is said to have given excellent control. Significant reductions were obtained in the infestation and increases in yield of the treated plots over the untreated plots. The naphthalene was used at the rate of 300 lb. per acre in each application, the most effective control having been secured by applying the naphthalene directly on the row.

Gladiolus thrips, Taeniothrips gladioli, E. I. McDANIEL (*Michigan Sta. Quart. Bul., 15 (1933), No. 3, pp. 168-172, fig. 1*).—A practical account.

The 1932 grasshopper outbreak, J. R. PARKER (*Jour. Econ. Ent., 26 (1933), No. 1, pp. 102-108*).—The occurrence and importance of grasshoppers in 1932 is reviewed.

Hibernation in Orthoptera.—I, Physiological changes during hibernation in certain Orthoptera, J. H. BODINE (*Jour. Expt. Zool., 37 (1923), No. 5, pp. 457-476, figs. 7*).—This first contribution deals with the physiological changes during hibernation in certain grasshoppers.

Hibernation and diapause in certain Orthoptera.—II, III, J. H. BOMINE (*Physiol. Zool.*, 5 (1932), No. 4, pp. 538-548, figs. 7; 549-554, figs. 4).—The second contribution deals with response to temperature during hibernation and diapause and the third contribution with diapause—a theory of its mechanism.

Observations on the Chinese mantid *Paratenodera sinensis* Saussure. S. W. BROMLEY (*Bul. Brooklyn Ent. Soc.*, 27 (1932), No. 4, pp. 196-201).—A brief account is given of the Chinese mantis, first established near Philadelphia, Pa., about 1896, and which now occurs in New York and New Jersey. Reference is also made to *Mantis religiosa* L., introduced from the Old World and now well established in New York about Rochester and Ithaca, where it was first reported in the summer of 1899. It has recently appeared on Long Island.

The economic status of the genus *Eurydema* with biological notes on *E. pulchrum* Westw. (Hemiptera, Pentatomidae). W. E. HOFFMANN (*Lingnan Sci. Jour.*, 11 (1932), No. 4, pp. 553-564, pl. 1).—Notes are presented on the food habits of species of *Eurydema*, particularly *E. pulchrum*, and on the life history of *E. dominulus* Scop., *E. oleraceum* L., and *E. ornatum* L. An account is given of the life history of *E. pulchrum*, together with a description of the several stages, natural and artificial control of *Eurydema* spp., *Eurydema* spp. as predators, a summary of plants attacked, and the economic status and control of *E. pulchrum* at Canton.

Report on the control of the Harlequin bug (*Murgantia histrionica* Hahn), with notes on the severity of an outbreak of this insect in 1932. H. G. WALKER and L. D. ANDERSON (*Jour. Econ. Ent.*, 26 (1933), No. 1, pp. 129-135).—In this contribution from the Virginia Truck Experiment Station it is pointed out that the severe outbreak of the Harlequin bug during 1932 in the Norfolk truck crop area was due in part to the mild winter of 1931-32 and to the abundance of preferred host plants in abandoned fields and in seed kale fields.

"The best control of this pest was obtained with sprays in which rotenone was the active ingredient in combination with a 1 percent soap solution. In general, nicotine, pyrethrum, and oil emulsion sprays were not effective for use against this insect, except at very strong concentrations. Swallows were observed feeding on the adult insects. The egg parasite, *Ooencyrtus johnsoni* (How.), was found to parasitize from 35 to 55 percent of all the Harlequin bug eggs collected during August and September."

Further studies of tarnished plant bug injury to celery. L. L. HILL (*Jour. Econ. Ent.*, 26 (1933), No. 1, pp. 148-150).—In further studies (E.S.R., 67, p. 709) it was found that sulfur dust, 300 mesh or better, when used alone as a dust or when combined with hydrated lime either as a dust or as a spray, has been most effective in reducing tarnished plant bug injury in both early and late celery. An average of five applications was found necessary for control. The cost of material in every case is considered moderate.

***Draeculacephala mollipes* Say, a cicadellid pest of apples.** P. W. CLAASSEN (*Jour. Econ. Ent.*, 26 (1933), No. 1, pp. 282-284, pl. 1).—An account is given of the injuries caused to the fruit and twigs of the apple by crescent-shaped oviposition punctures of the sharp-nosed leafhopper (*D. mollipes*). The females make a crescent-shaped cut, 3-4 mm long, through the skin of the apple or twigs and deposit from a few to more than 20 eggs within each egg puncture. As many as 125 egg punctures have been found on a single apple. The injury is largely restricted to the fruit and twigs on the lower portion of the tree.

Laurel-sumac as a source of red scale infestation. W. EBELING (*Calif. Citrogr.*, 18 (1932), No. 1, p. 4, figs. 2).—In this contribution from the Cali-

fornia Citrus Experiment Station attention is called to the importance of destroying the laurel-sumac growing adjacent to citrus plantings, particularly if the shrub is known to be infested with red scale.

The codling moth and its control, L. HASEMAN (*Missouri Sta. Circ.* 169 (1933), pp. 4, figs. 2).—A practical account.

The oriental moth (*Cnidocampa flavescons* Walk.) in Massachusetts and the work of its newly introduced parasite, C. W. COLLINS (*Jour. Econ. Ent.*, 26 (1933), No. 1, pp. 54-57).—The establishment and distribution of the oriental moth in Massachusetts is called to attention, and its favored food plants, seasonal history, and artificial control are noted. Especial attention is given to the introduction of a tachinid parasite (*Chactezorista javanica* B. & B.) from Japan, its quick establishment, and the rather high degree of control effected within three and four years after the first introduction.

The European corn borer situation in the United States at the close of 1932, D. J. CAFFEY and L. H. WORTHLEY (*Jour. Econ. Ent.*, 26 (1933), No. 1, pp. 85-102).—A review of the present distribution and importance of and control work with this pest in the United States.

Laboratory production of clusters of European corn borer eggs for use in hand infestation of corn, L. H. PATCH and L. L. PEIRCE (*Jour. Econ. Ent.*, 26 (1933), No. 1, pp. 196-204, pls. 2).—The authors report upon a practical method of producing corn borer egg clusters in the laboratory for use in experimental infestation of corn.

Possibilities of combating wattle bag-worm with insecticidal dusts, L. B. RIPLEY and B. K. PETTY (*So. African Jour. Sci.*, 29 (1932), pp. 544-561, figs. 7).—In control work with *Acanthopsyche junodi* Heyl., data were obtained on the relative insecticidal efficacy and relative repellence of 12 different poisons at varying dosages.

Observations on cultural practices for the control of the potato tuber worm, *Phthorimaea operculella* Zell., G. S. LANGFORD (*Jour. Econ. Ent.*, 26 (1933), No. 1, pp. 135-137).—A summary is given of experimental tests made on hilling or ridging potatoes for the control of the potato tuber worm. Ridged culture was found effective in reducing tuber injury if applied properly and timely.

The coffee clear wing hawk moth (*Cephonodes hylas* L.), G. H. CORBETT and M. Y. SHARIFF (*Malayan Agr. Jour.*, 20 (1932), No. 10, pp. 508-517, pl. 1).—A description is given, including the several stages and instars, of *C. hylas*, followed by a discussion of the economic importance, seasonal history and habits, life cycle, enemies, and means of control.

Tartar emetic as a poison for the tobacco hornworm moths.—A preliminary report, J. U. GILMORE and J. MILAM (*Jour. Econ. Ent.*, 26 (1933), No. 1, pp. 227-233, fig. 1).—In tests made of 40 materials during several seasons in an effort to discover an efficient stomach poison for the tobacco hornworm moths (the tomato worm and the tobacco worm), it was found that a 5 percent solution of tartar emetic is an effective and satisfactory poison when used in conjunction with isoamyl salicylate as an attractant. Large-scale field experiments have been conducted for three successive seasons with promising results.

The lesser peach borer (*Aegeria pictipes* G. & R.), M. A. VOGEL and R. B. NEISWANDER (*Ohio Sta. Bimo. Bul.*, 18 (1933), No. 2, pp. 51-54, figs. 2).—A brief practical account of this pest and means for its control. Paradichlorobenzene dissolved in crude cottonseed oil, at the rate of 1 lb. of the chemical to 2 qt. of the oil, has proved to be an efficient means of controlling the pest.

The sorghum worm in Missouri, L. HASEMAN (*Missouri Sta. Bul.* 320 (1933), pp. 8, figs. 6).—The sorghum webworm, a small woolly or spiny caterpillar known to science for many years, first appeared as a pest in Missouri in 1921, at which time it completely destroyed the sorghum grain crop over thousands of acres and greatly reduced the yields where it was less abundant. It reappeared in 1922 and 1923, doing considerable damage in restricted areas. From this time it continued to cause some injury, though more restricted in its distribution, until 1929 and 1930, when it was destructive in some parts of southeastern Missouri.

The webworm is most destructive to grain sorghums, kafir as a rule suffering most, although milo and feterita are also seriously attacked. In 1921 growers in 11 counties reported from 70 to 100 percent of their seed crop destroyed by the pest. The caterpillars of the early summer brood appeared in southeastern Missouri in 1922 in great numbers on ripening rye and on the heads of timothy, doing considerable damage in some rye fields. It was also found feeding on corn and on wild grasses, records showing it to be confined to plants of the grass family and to be most destructive on the unripe seed of the grain and sweet sorghums. The caterpillar feeds on the soft or maturing grain, hollowing the grain out so that practically nothing is left.

The sorghum webworm is multiple brooded (apparently three broods each year in Missouri), the heavy damage to the grain sorghums being caused by the larvae between the middle of August and the middle of October. It passes the winter in the almost full-grown larval stage, molts once in the spring, and feeds for a few days before pupating. At Perryville hibernating larvae in the upper part of broomcorn stalks taken in January 1924 remained in the larval stage until June 10, and one pupated without receiving food. In 1922 larvae were found on June 8 at Cape Girardeau feeding and damaging rye and timothy heads. In the laboratory they began to emerge as moths on June 14 and some emerged as late as July 3. Technical descriptions are given of the several stages.

The parasites reared include *Apanteles* n.sp.; *Catolaccus acnoviridis* Gir., probably a parasite of *Apanteles*; an egg parasite, *Trichogramma minutum* Riley; and *Eupelmus popa* Gir. Insecticidal control of the pest is considered impractical. There are, however, a number of farm practices which the grower can use in controlling the pest and protecting the crop. These include timing the seeding of the crop so that most of the grain will be past the soft attractive stage before the heavy swarms of worms appear in September, disposal of the fodder and unthreshed grain heads before spring, pasturing the sorghum fields in the winter, plowing infested fields after the crop is removed in the fall or early winter, and burning fence rows and adjoining waste areas.

Observations on the susceptibility of animal fibres to damage by the larvae of two species of clothes moth, *Tineola biselliella* Hummel and *Tinea pellionella* L., R. BURGESS and E. J. POOLE (*Jour. Textile Inst.*, 22 (1931), No. 3, pp. T141-T157).—Observations on the susceptibility of animal and vegetable fibers to damage by the larvae of the webbing clothes moth and the case-bearing clothes moth led to the following conclusions:

"Vegetable fibers and silk are not attacked by the above-mentioned species of clothes moth. Certain animal fibers such as alpaca, camel's hair, cashmere, and goat hair are highly susceptible to attack, particularly when in their natural state. The natural fleece of the sheep is also readily attacked, but in the cases examined the process of scouring enhanced further its susceptibility. Partially processed sheep's wools containing vegetable oil are not favored by

clothes moth larvae, although such materials may not be considered to be immune from their activities. Fatty acids, applied in a concentration as high as 5.2 percent on the weight of wool, do not produce complete immunity. In this respect, these substances are inferior to certain mineral oils examined. Worsteds cloth impregnated with solutions of "Larvex" and "Eulans" are satisfactorily proofed against the action of clothes moths. Infected wool stored in a closed atmosphere containing paradichlorobenzene is also efficiently protected."

The status of the European pine shoot moth in Connecticut, R. B. FRIEND and H. W. HICOCK (*Jour. Econ. Ent.*, 26 (1933), No. 1, pp. 57-62).—In this contribution from the Connecticut State Experiment Station attention is called to the establishment of the European pine shoot moth as a serious enemy of red pine in Connecticut and its relation to forest plantings of this tree.

Observations on the tomato pin worm (*Gnorimoschema lycopersicella* Busck) and the egg plant leaf miner (*G. glochinella* Zeller) in Pennsylvania, C. A. THOMAS (*Jour. Econ. Ent.*, 26 (1933), No. 1, pp. 137-143, fig. 1).—The author reports that *G. lycopersicella* was found for the first time in Pennsylvania in 1931 (E.S.R., 67, p. 50) and appears to have been eradicated there by certain greenhouse practices. A description is given of the various stages of this lepidopteran and of the injury caused by it. Notes are also given on the occurrence of the eggplant leaf miner in the same area, and on several parasites reared from its larvae.

Further notes on the bee moth, F. B. PADDOCK (*Jour. Econ. Ent.*, 26 (1933), No. 1, pp. 177-181).—The author reports upon recent information obtained on the distribution, life history, and parasites of and control methods for the wax moth.

Diamond-back moth (*Plutella maculipennis* Curt.) in connection with the cultivation of mustard [trans. title], O. È. TSEDELER (*Zhur. Opytn. Agron. Iugo-Vostoka* (*Jour. Agr. Sci. S.-E. of U.S.S.R.*), 9 (1931), No. 2, pp. 165-195, figs. 5; *Eng. abs.*, pp. 194, 195).—This is an account of a study of the life history, bionomics, and control of the diamond-back moth, of particular importance in the lower Volga region, U.S.S.R., in connection with the cultivation of mustard, of which there has been an expansion in the acreage grown.

The response of corn earworm moths to various sugar solutions, L. P. DITMAN and E. N. CORY (*Jour. Econ. Ent.*, 26 (1933), No. 1, pp. 109-115, fig. 1).—The authors report that corn ear worm moths responded in varying degrees to 10 sugars in solutions. On the basis of molar concentrations sucrose, invert sugar, and fructose proved most attractive in the order named.

Review of six seasons work in Louisiana in controlling the sugar cane moth borer by field colonizations of its egg parasite *Trichogramma minutum* Riley, W. E. HINDS, B. A. OSTERBERGER, and A. L. DUGAS (*Louisiana Stas. Bul.* 235 (1933), pp. 36, figs. 2).—This is a review of the control work with the sugarcane borer by the use of the egg parasite *T. minutum* commenced in 1927, with particular attention to the control tests in 1932.

"In corn, among 8 comparable check fields the natural parasitism increased between June 15 and July 30 from 17.4 to 53.5 percent average (an increase of threefold), while among 11 colonized areas averaging 16.3 percent parasitism before colonization, the addition of 6,000 *Trichogramma* per acre enabled these fields to show 82.8 percent average parasitism at the end of July (an increase to fivefold).

"Among the cane fields compared, the natural parasitism occurring at the start was 6.9 percent in all checks, 11.3 percent in all colonized, and 3.3 percent in all adjacents which received most of their parasite supply from nearby,

colonized cornfields. In 3 weeks the percentage had increased fivefold in colonized, fivefold in adjacent, and threefold in check areas. Through the balance of the season the parasitism in colonized and adjacent areas continued far higher than in the checks, averaging approximately 28 percent above checks to September 10.

"Correlation studies show that in all check areas there was an average of 31.8 percent of the cane joints bored and a moth population of 6,057 produced in millable cane through the season. Compared with these figures, all colonized fields showed 13.5 percent of joints bored and 3,422 moths per acre, while adjacent fields had 12.3 percent of joints bored and 2,164 moths per acre.

"With an initial total stand averaging 34,880 sprouts in all 31 protected areas and 35,720 in 28 checks, there were 19,289 millable stalks per acre produced in checks and 25,288 in all protected areas. The difference of 6,000 millable stalks per acre, or a saving of over 30 percent of the check stalk yield, is indicated as one benefit from colonization work. We find a consistent and very significant saving in pounds of sugar produced per ton of cane. The saving ranged from 6.52 lb. per ton with 807 (the most resistant variety) to 25.83 lb. per ton with 213. The general average saving shown as a composite of all varieties was 20.92 lb. of sugar per ton of cane.

"The cost of colonization work averaged \$1 per acre in 1932. The six sets of plantation records secured in 1932 showed an average yield of 15.63 tons per acre in six check areas with natural parasitism and 18.91 tons in six protected areas. The average saving or gain in yield was 3.28 tons per acre. In these six fields there was an average increase of 22.38 lb. of sugar per ton of cane produced as compared with 20.92 lb. for all of our test areas as measured by field samples. The gross value of the increased yield of sugar per acre in six protected areas at 3 c. per pound was \$29.04 per acre."

Sugarcane borer control by *Trichogramma* colonization in Louisiana in 1932. W. E. HINDS, B. A. OSTERBERGER, and A. L. DUGAS (*Sugar Bul.*, 11 (1933), No. 7, pp. 2, 4).—This is a general statement of the results of and conclusions drawn from work with *T. minutum* colonization in 1932, contributed from the Louisiana Experiment Stations (E.S.R., 67, p. 156), the details of which are above noted.

"Our general conclusion from all of this work is that *Trichogramma* colonization, as tested by experiment station workers and practiced by numerous growers in 1932, resulted in a very substantial reduction in cane borer multiplication and damage to sugarcane and a corresponding increase in tonnage of millable cane and in the amount of sugar produced per ton of cane."

Further investigations on the racial differentiation of *Anopheles maculipennis* in the Netherlands and its bearing on malaria. A. DE BUCK, E. SCHOUTE, and N. H. SWELLENGREBEL (*Riv. Malariol.*, 11 (1932), No. 2, pp. 137-156, pl. 1, figs. 2; *Ital., Fr., Eng., Ger. abs.*, pp. 265, 267, 269, 271).—In this contribution (E.S.R., 64, p. 159) the authors confirm earlier findings as regards different sexual habits and morphological differences in the two races of the malaria mosquito *A. maculipennis*.

Notes on the infectivity, food, and breeding waters of anophelines in Kenya. C. B. SYMES (*Kenya Med. Dept., Rec. Med. Res. Lab.*, No. 4 (1932), pp. 28, pl. 1).—In this report of observations much of the data is presented in tabular form.

The problem of mosquito control in Delaware. L. A. STEARNS, D. MCCREARY, and N. P. NEWHOUSE (*Delaware Sta. Bul.* 181 (1933), pp. 106, figs. 31).—Following a brief introduction, the authors take up the outstanding features of the survey made during the months of May to September, inclusive, in 1932

for 16 representative communities throughout the State, survey objectives, investigational procedure, a summary of trap collection records, community surveys (pp. 21-65), summary of mosquito breeding in 1932 (pp. 66-69), biology of the species of mosquitoes collected during 1932 (pp. 70-89), topography of the State in relation to its mosquito control problem (pp. 90-94), the general problem of mosquito control (pp. 94-97), problem of mosquito control in Rehoboth area (pp. 97-102), and organization for mosquito control in Delaware (p. 102).

Records of the mosquito fauna in the several localities in which nightly samples were made of the mosquito fauna by means of a mechanical collecting device, and including a total of 98,922 adult mosquitoes, indicate that at least 28 species comprise the mosquito population of the State. On a percentage basis, the saltmarsh group of mosquitoes (saltmarsh mosquito, brown saltmarsh mosquito, *Aedes taeniorhynchus* Wied., and *Culex salinarius* Coq.) constitutes 41 percent and the house mosquito (*C. pipiens* L.) 36 percent of the total mosquito population of the State. With these five species responsible for approximately three fourths of the annoyance experienced, an additional five species, *A. vexans* Meig. (the inland swamp mosquito), *Mansonia perturbans* Walk., and the three anophelines *Anopheles quadrumaculatus* Say (the malarial mosquito), *A. crucians* Wied., and *A. walkeri* Theob., contribute largely to the remaining one fourth.

The present data indicate conclusively that freedom from the mosquito nuisance throughout a greater part of the State depends largely upon the control of the saltmarsh group of mosquitoes through the elimination of those areas in which they are bred. These species constitute from 74 to 89 percent of the total mosquito population of Milton, Bethany Beach, Rehoboth Beach, Dover, and Lewes and of adjoining areas. The saltmarsh areas of the State comprise a total of 107,456 acres. Adequate treatment would necessitate large-scale operations, including ditching, diking, hydraulic fill, flooding, etc.

Mosquitoes kill live stock, F. C. BISHOPP (*Science*, 77 (1933), No. 1987, pp. 115, 116).—An outbreak of the mosquito *Psorophora columbiana* Dyar and Knab in Florida, which resulted in the death of at least 173 head of livestock and poultry, including 80 cattle, 67 hogs, 3 horses, 1 mule, 20 chickens, and 2 dogs, is recorded. It is thought that death may have been due to injection of a toxin by the mosquitoes as well as to the loss of blood.

Observations on the Mexican fruit fly and some related species in Cuernavaca, Mexico, in 1928 and 1929, M. McPHAIL and C. I. BLISS (*U.S. Dept. Agr. Circ.* 255 (1933), pp. 24, figs. 6).—A report of observations, particularly of the Mexican fruit fly (officially known as the orange maggot), conducted during parts of the seasons 1928 and 1929 in the heavily infested region in and about Cuernavaca, Morelos, south of México, D.F. The fly bred most abundantly in mango and throughout the year it occurred in smaller numbers in sweet lime, orange, peach, and pomegranate, and occasionally in guava, but because of the frequency of off-season mangoes none of these was an essential alternate host. Guavas were infested normally by the Central American fruit fly (*Anastrepha striata* Schin.), a species which seldom occurred in other fruits. A third species, the West Indian fruit fly, occurred in smaller numbers almost entirely in the yellow mombin, or native "plum".

"Parasitism was confined largely to *Opius crawfordi* Vier., which laid its eggs in the infested mangoes. Parasitized larvae formed apparently normal puparia, from which adult parasites emerged about a day and a half later than did unparasitized flies. The parasite seemed to attack older larvae of *A. ludens* more successfully than younger ones. The percentage of parasitism varied with the season, increasing rapidly as the mangoes ripened, from 1.4 percent in April to 27.8 percent in June in dropped fruits. Three other parasites

have been reared from fruit-fly pupae in small numbers: *Galesus* sp., *Eucolia* sp., and *Anthrax scylla* O.S."

Results of dusting experiments to control the blueberry maggot, L. C. McALISTER, JR. (*Jour. Econ. Ent.*, 26 (1933), No. 1, pp. 221-227).—Experiments conducted during 1931 demonstrated that two applications of calcium arsenate will produce blueberries free from the blueberry maggot under conditions of moderate infestation, although the insect may not be completely eradicated. "Three applications of calcium arsenate will further reduce the maggot infestation, but there is increased danger of excessive arsenical residue. One application of calcium arsenate was found to be inadequate under ordinary circumstances. The calcium arsenate may be diluted with an equal quantity of hydrated lime and remain effective. Copper carbonate used as a dust in one field test reduced the number of maggots 97.11 percent."

The use of blowfly maggots in the treatment of osteomyelitis and certain other diseases, W. ROBINSON (*U.S. Dept. Agr., Bur. Ent.*, 1932, pp. 2).—A brief account, in multigraphed form, of the use made of blowfly maggots in the treatment of surgical osteomyelitis.

The rearing of blowflies and the culture of sterile maggots for use in osteomyelitis, W. ROBINSON (*U.S. Dept. Agr., Bur. Ent.*, 1932, pp. 8).—An account in multigraphed form is given of the essential features of the life history and habits of blowflies, general methods of rearing adults and maggots, the technic applied in the production of sterile maggots, and the entomological aspects of the maggot treatment for surgical osteomyelitis.

Surgical maggots in the treatment of infected wounds: Culture of sterile maggots, W. ROBINSON (*Jour. Lab. and Clin. Med.*, 18 (1933), No. 4, pp. 406-412).—This contribution is accompanied by a list of 22 references to the literature.

An efficient medium for rearing houseflies throughout the year, H. H. RICHARDSON (*Science*, 76 (1932), No. 1972, pp. 350, 351).—In studies made of the rearing of large numbers of house flies continuously throughout the year for use in various lines of research, it was found that a wheat bran-alfalfa meal mixture, supplemented with small amounts of yeast and Diamalt (a commercial product composed of a large percentage of malt sugar), provided a very satisfactory larval medium. The formula found most satisfactory for this medium consists of (1) wheat bran 3.25 lb. and alfalfa meal 1.75 lb., thoroughly mixed, and (2) water 5,000 cc, yeast suspension 300 cc, and Diamalt 25 cc, also thoroughly mixed together. The water mixture should be added to the bran mixture and thoroughly stirred, following which the house fly eggs may be added immediately.

Preliminary report on controlling the winter emergence of the Japanese beetle in rose greenhouses by application of chemicals to the soil, F. W. METZGER (*Jour. Econ. Ent.*, 26 (1933), No. 1, pp. 205-210, fig. 1).—This contribution reports upon preliminary results obtained in an effort to control the injury to roses in greenhouses caused by Japanese beetles emerging during the winter months and feeding on the plants, through treating beds containing five varieties of roses with various materials.

"Lead arsenate and barium fluosilicate used at the 3,000-lb. rate gave practically 100 percent control, but as the latter material was used at only one concentration no comparison of the lower rates can be made." Further data are considered necessary to determine the practical value of the treatments.

Japanese beetle (*Popillia japonica*), R. HUTSON (*Michigan Sta. Quart. Bul.*, 15 (1933), No. 3, pp. 166-168, fig. 1).—A brief practical account.

Present status of two Asiatic beetles (*Anomala orientalis* and *Autoserica castanea*) in the United States, H. C. HALLOCK (*Jour. Econ. Ent.*, 26 (1933),

No. 1, pp. 80-85, pls. 3, figs. 2).—The author considers the distribution and importance of the Asiatic beetle and the Asiatic garden beetle *Autoserica castanea* Arr. in the United States. An account of the life history and control of the latter pest by the author has been noted (E.S.R., 68, p. 791).

Observations on the biology and control of *Metriona bivittata* Say, L. A. STEARNS (*Jour. Econ. Ent.*, 26 (1933), No. 1, pp. 151-154, pls. 2).—The author reports upon a localized but destructive outbreak of the two-striped sweetpotato beetle *M. bivittata* near Laurel, Del., in 1932, further demonstrating the ability of this species to effect extensive damage. "At the height of the infestation, during the first week in July, a tachinid, *Anetia dimmooki* Ald., was responsible for a 12 percent larval parasitism. The results of a single application on July 6, to severely affected areas, of lead and calcium arsenates, in dust form undiluted, indicate that both materials were practically 100 percent effective for control of this insect and caused but slight injury to the plants. The acreage so treated on that date showed subsequently an almost complete recovery and produced a satisfactory crop."

Cultural practices in relation to Mexican bean beetle control, N. TURNER and R. B. FRIEND (*Jour. Econ. Ent.*, 26 (1933), No. 1, pp. 115-123, figs. 4).—In this contribution from the Connecticut State Experiment Station the effect of spacing of bean plants on injury by the Mexican bean beetle and on the efficiency of control measures is discussed.

Insecticides for the control of the Mexican bean beetle, N. F. HOWARD, L. W. BRANNON, and H. C. MASON (*Jour. Econ. Ent.*, 26 (1933), No. 1, pp. 123-129).—Field tests which have extended over a period of 3 years indicate that potassium hexafluoroaluminate and synthetic cryolite are satisfactory for the control of the Mexican bean beetle when used as sprays at the rate of 3 lb. to 50 gal. of water. "Barium fluosilicate (80 percent) must be used at the rate of 5 lb. to 50 gal. of water to give satisfactory control, and is considered too expensive to be recommended. These compounds have not given satisfactory control when used as dusts. There appears to be no advantage in changing current recommendations for the use of magnesium arsenate except that the dosage should be increased from 1 lb. to 2 lb. to 50 gal. of water where the infestation is heavy. If fluorine compounds are used, the problem of poisonous residues on green beans is not avoided, and green beans should not be sprayed with any of the above compounds after the pods have set."

***Oldes decempunctata* (Billberg), a chrysomelid pest of cultivated grape (*Vitis lambrusca* Linn.), W. E. HOFFMANN** (*Lingnan Sci. Jour.*, 11 (1932), No. 4, pp. 565, 566, pls. 2).—A brief account is given of a chrysomelid which attacks cultivated grape in the vicinity of Canton.

Barium fluosilicate as a control for the tobacco flea beetle, F. S. CHAMBERLIN (*Jour. Econ. Ent.*, 26 (1933), No. 1, pp. 233-236).—This is a report of experimental work with barium fluosilicate in combating the tobacco flea beetle on shade-grown tobacco in Georgia and Florida.

Chloropicrin as a soil insecticide for wireworms, M. W. STONE and R. E. CAMPBELL (*Jour. Econ. Ent.*, 26 (1933), No. 1, pp. 237-243).—Experiments in California with chloropicrin in dilute solutions have shown that it is toxic to wireworms, but that its use on a large scale would be very expensive.

Field experiments with various poison baits against wireworms, *Limoni* (*Pheletes*) *canus* Lec., R. S. LEHMAN (*Jour. Econ. Ent.*, 26 (1933), No. 1, pp. 243-252).—The results obtained from the use of some 125 organic and inorganic compounds at different concentrations in ground whole-wheat baits in combating the wireworm *L. (P.) canus* are presented in tabular form. Arsenic compounds were found to be definitely repellent. Paraphenylenedia-

mine was the only compound which showed any promise as an effective poison in these baits.

The vegetable weevil (*Listroderes obliquus*), O. H. LOVELL (*California Sta. Bul.* 546 (1932), pp. 19, figs. 6).—The vegetable weevil has been known to occur in California about the San Francisco Bay region since 1926 and is now found in 11 counties in the State. It is active throughout the fall, winter, and spring months. "The larva does considerable damage to truck crops, especially carrots, turnips, and spinach, in the fall and winter, while the adult does most of its damage to tomatoes and potatoes in the late spring and early summer. After June the weevil goes into estivation and remains inactive until September.

"The vegetable weevil is best controlled by dusting infested carrots, turnips, and spinach with either sodium fluosilicate or barium fluosilicate of 70 to 80 percent strengths at the rate of 30 to 40 lb. of dust per acre when the foliage is dense and at the rate of 15 to 25 lb. when the foliage is thin. The dust should be evenly distributed. It is best done by a rotary duster with a fan-shaped nozzle. For larger acreages a power duster is most efficient. For the control of the weevil on young tomato plants a knapsack, or bellows, duster is recommended. A puff or two to each plant, or enough to cover thoroughly the foliage and the ground at the base of the plant, will give the plants protection; 10 to 12 lb. per acre is sufficient."

Field sanitation is next in importance in reducing the damage due to attack by this pest. Crop rotation and thorough cultivation are other means of reducing the weevil population and should be used when possible. Poison baits may also be used to advantage in some instances.

A cage for confining weevils on the fruit and foliage of trees, T. L. BISSELL (*Jour. Econ. Ent.*, 26 (1933), No. 1, p. 176).—A description is given of a simple cage which has proved satisfactory for caging adults of the pecan weevil on growing nuts and foliage for insecticide tests.

Life history and distribution of the low-tide billbug, *Calendra setiger* (Chittenden), A. F. SATTERTHWAIT (*Jour. Econ. Ent.*, 26 (1933), No. 1, pp. 210-217).—This is a report of a study of *C. setiger*, which breeds, so far as known, chiefly below high tide mark in salt reed grass (*Spartina cynosuroides*) in maritime marshes along the Atlantic coast.

"Reared indoors and in corn pith, larvae developed essentially in the same number of instars and in the same period of time as do species commonly attacking corn. A careful study of the immature stages indicates that the egg stage approximates 5 days, the larval stage 45 days for the 6-instar larvae and 51 days for the 17-instar larvae, and the pupal stage 10 days. Measurements of eggs, head widths of larvae, and pronotal widths and total lengths of pupae have been recorded. Beetles reared from eggs laid in captivity were healthy, wintered successfully, matured, and laid eggs from which a second generation of adults was reared.

"This billbug's ability to adapt itself immediately to corn tissue and to a complete absence of sea water indicates its potentiality as a corn destroyer in the event that any sod land infested by it is directly converted to a cornfield. In its larval and adult stages it is known to feed on salt reed grass, which is used to some extent as a wild hay."

Some observations on *Hylobius pales* Herbst, H. H. YORK (*Jour. Econ. Ent.*, 26 (1933), No. 1, pp. 218-221, pl. 1).—These observations relate to a weevil which works in stumps and at the root crown of pitch pine and white pine in several localities in New York State.

The biology of *Opius melleus* Gahan, a parasite of the blueberry maggot, F. H. LATHROP and R. C. NEWTON (*Jour. Agr. Res. [U.S.]*, 46 (1933), No. 2,

pp. 143-160, figs. 6).—This is a report of studies of the biology of *O. melleus* made during the course of investigations of the blueberry maggot in eastern Maine from 1925 to 1929, inclusive. Records of adults captured in emergence cages indicated parasitism of the blueberry maggot by *O. melleus* ranging from 1.37 to 29.66 percent. Examinations of the puparia indicated parasitism ranging from 3.28 to 49.42 percent.

A thorough study of the problem has shown that the determination of the percentage of parasitism of isolated samples does not indicate the effective seasonal parasitism by *O. melleus*. The most accurate estimate of the total seasonal parasitism was made by plotting the seasonal populations of maggots of the third instar and of parasites, and comparing the areas enclosed by the respective curves. The percentage of parasitism alone, however, does not necessarily indicate the potential value of the parasite in reducing the population of the blueberry maggot, for a number of other factors, such as relative rates of reproduction and ecological competition, must be taken into consideration. It appears that this parasite is not actively reducing the population of the blueberry maggot, and that it will probably never have this effect unless some marked change in the environment of the species should occur. It seems clearly indicated, however, that this parasite is an important ecological factor in the balance which apparently exists in the blueberry maggot association.

The female parasite deposits the egg directly into the body of the maggot, the egg hatching within from 3 to 6 days. The parasite larva swims freely in the body cavity of the maggot, without injury to the host until the host puparium is formed. Larvae may be found in the maggots from early August until frost occurs, usually in late September or early October. Laboratory studies indicated that the average length of life of the adult parasite was 17.5 days, with no significant difference in the longevity of males and females. The simultaneous study of data from field counts and the emergence records indicates an average length of life of approximately 20 days.

The interrelations of two hymenopterous egg parasites of the gipsy moth, with notes on the larval instars of each, D. L. PARKER (Jour. Agr. Res. [U.S.], 46 (1933), No. 1, pp. 23-34, figs. 6).—This is a report of observations of the interrelations of *Anastatus disparis* Ruschka and *Oocencyrtus kuvanae* (How.), two important hymenopterous egg parasites of the gipsy moth which have become well established over a considerable part of the area of New England infested by this moth.

It appears that there is little serious competition between the two parasites. While *O. kuvanae* females can attack a host egg containing *A. disparis* from the time this insect is in the egg stage until it has become an early third-instar larva, *A. disparis* does not suffer from the attack. An egg containing *O. kuvanae* throughout its egg, larval, and pupal life is to some extent susceptible to attack by *A. disparis*, but except for successful oviposition while *O. kuvanae* is in the egg stage, which results in *A. disparis* developing, neither of the parasites succeeds in completing development. Since there is little conflict between the parasites in the same area under the conditions simulated in the experiments, the presence of the two may be considered advantageous, for parasitism by *O. kuvanae* affords additional control to that effected by *A. disparis*. *A. disparis*, however, is the preferred parasite (1) because it is a single-generation parasite having a life history which coincides very closely with that of the host itself and (2) because it hibernates successfully in the area of New England infested by the gipsy moth. *O. kuvanae* is multiple brooded and depends largely upon infertile and killed host eggs for the early spring generation. It hibernates as an adult, and suffers great losses during the winter months.

In the course of the investigations it was noted that, contrary to the general belief, there are five rather than three larval instars in the case of both the parasites. Short descriptions of the larvae are given, and the larval mandibles of both parasites are illustrated.

The new beekeeping, E. F. PHILLIPS (*Jour. Econ. Ent.*, 26 (1933), No. 1, pp. 155-162).—This is a discussion of developments in practical beekeeping methods based on investigations and experience regarding the need of colonies of bees in winter and spring, special attention being given to the size and arrangement of the hive. The 2-story Langstroth hive is advised for winter, the upper story being filled with honey.

Nectar secretion of the tuliptree or yellow poplar, G. E. MARVIN (*Jour. Econ. Ent.*, 26 (1933), No. 1, pp. 170-176, fig. 1).—A study of the quantity of nectar secreted per blossom of the yellow poplar and the sugar content of this nectar has shown the average weight of nectar secreted by one flower to be 1.6417 g. The average sugar content of nectar from freshly opened blossoms was 16.7 percent. After the flower was open, the concentration of the nectar increased until on the second day it reached 35.9 percent. The tree under observation was calculated to yield sufficient nectar to produce 2.16 lb. of honey.

Studies on the rate at which honeybees ripen honey, O. W. PARK (*Jour. Econ. Ent.*, 26 (1933), No. 1, pp. 188-193, fig. 1).—In this contribution from the Iowa Experiment Station the author reports that "nectar containing 45 percent sugar when brought into the hive was found to contain approximately 60 percent sugar when first deposited in the comb. Other results show that combs of green honey left in the hive but screened from the bees advanced in concentration from 65 percent to 80 percent, the concentration of ripe honey, within 3 days."

Buckeye poisoning of the honeybee.—A progress report, J. E. ECKER (*Jour. Econ. Ent.*, 26 (1933), No. 1, pp. 181-187).—This is a progress report of work with buckeye poisoning of the honeybee, contributions on which by Vansell et al. have been noted (E.S.R., 55, p. 56; 67, pp. 720, 721).

Preliminary observations on "paralysis" of honeybees, C. E. BURNSIDE (*Jour. Econ. Ent.*, 26 (1933), No. 1, pp. 162-168).—The author reports upon experiments in which "paralysis" appeared to be successfully transmitted among bees in cages and among bees in colonies. "Brood from affected colonies when placed in healthy colonies produced bees which remained healthy. Conversely, brood from healthy colonies when placed in affected colonies produced bees many of which were later affected by paralysis. The results obtained seem to indicate that paralysis of adult honeybees is a slightly infectious disease that is transmitted directly from sick or dead bees to healthy ones."

A plant poisonous to adult bees, G. H. VANSSELL and W. G. WATKINS (*Jour. Econ. Ent.*, 26 (1933), No. 1, pp. 168-170).—A brief account of the poisoning of bees moved into the Sierra Nevada Mountains of California in 1932 while visiting the blossoms of western false hellebore (*Veratrum californicum*).

Efficiency and economy in apiary inspection, R. G. RICHMOND (*Jour. Econ. Ent.*, 26 (1933), No. 1, pp. 194-196).—A description of a method of organization for apiary inspection suitable for present economic circumstances which has been applied in Colorado and found entirely satisfactory.

Chemical control of the garden centipede, *Scutigera immaculata*, A. E. MICHELbacher (*California Sta. Bul.* 548 (1932), pp. 19, fig. 1).—In experiments with chemicals for control of *S. immaculata* (Newp.), accounts of which pest by Wymore in California (E.S.R., 66, p. 456), Filing in Ohio (E.S.R., 66, p. 253), Riley in Indiana (E.S.R., 61, p. 663), and others have been noted,

carbon disulfide, carbon disulfide emulsion, carbon tetrachloride, chloropicrin, and calcium cyanide killed rapidly, with at least the first three exerting their fullest killing power during the first 24 hours. Paradichlorobenzene and naphthalene appeared to kill rather slowly, with the lethal action of paradichlorobenzene lasting until apparently all the centipedes are killed.

"Of the chemicals experimented with, the only ones that showed promise in the control of the garden centipede were paradichlorobenzene, carbon disulfide, and carbon disulfide emulsion, when the rate of application was heavy enough. While carbon disulfide emulsion did not give good results when used in the experimental plats, it has given satisfactory control under certain greenhouse conditions. It is effective only when the centipedes are concentrated near the surface of the soil and the soil is loose, porous, and moist so that the emulsion penetrates it readily. Paradichlorobenzene proved effective when used at the rate of 600 and 900 lb. per acre. This chemical should be applied only in the summer when the soil temperature is high, if effective control is to be obtained. Carbon disulfide proved effective when used at the rate of 145 and 290 gal. per acre. The effectiveness of the 145-gal. treatment is believed to be due to the fact that it was applied under most favorable conditions. Paradichlorobenzene and carbon disulfide are both injurious to vegetation and, therefore, their use is mostly limited to areas free of growing plants. Carbon disulfide emulsion has an advantage over the above-mentioned chemicals in that it can be applied to many different kinds of plants without causing injury to most of them.

"Because of cost, chemical control of the centipede under field conditions will probably prove uneconomical in most cases, although on small areas and in greenhouses such treatment may be profitable."

ANIMAL PRODUCTION

[Experiments with livestock in Alaska], W. T. WHITE (*Alaska Sta. Rpt. 1931-1932*, pp. 19-22).—Studies at the station have produced results noted on the feeding and breeding of Galloway-Holstein cows for milk production, the feeding and management of brood sows, carcass tests with yak-Galloway hybrids, the making of silage from sliced potatoes and freshly cut hay, and mosquito repellents for cattle on pasture.

[Investigations with livestock in California] (*California Sta. Rpt. 1932*, pp. 13-15, 18-21).—In tests with sheep results are reported on fattening rations for lambs, effects of plane of nutrition on various factors related to wool, amount of yolk in wool, suitability of branding fluids, and the value of rams of five different breeds for producing market lambs.

Swine studies were concerned with inbreeding Berkshire hogs, the value of whey for feeding with various feeds, casein as a feed for hogs, relation of diet to changes in the blood calcium, and relation of barley to leg stiffness in swine.

The poultry experiments have yielded information on supplying vitamins to poultry, yeast for correcting egg production and mortality during the pullet year, protein analyses of commercial fish and meat scraps, a comparison of wheat and barley for laying birds, the value of grit in poultry rations, the cause of watery whites in eggs during storage, inheritance of egg quality and of feather characters, pedigree breeding of turkeys, sex determination in chicks, and size and position of embryos.

[Experiments with livestock in Delaware] (*Delaware Sta. Bul. 179 (1932)*, pp. 21, 22, 23-25).—Experiments with hogs have yielded information on protein

supplements for hogs, winter rations for brood sows, and forage crops for swine, all by A. E. Tomhave.

The poultry studies report data on the utilization of ground soybeans for poultry, rations for growing pullets, germinated oats for laying birds, and confinement of laying birds without succulent green feed, all by Tomhave and C. W. Mumford.

[Investigations with livestock in Indiana] (*Indiana Sta. Rpt. 1932, pp. 22-24, 49-52, 56, 57, 59, 60, figs. 3*).—Results obtained in studies with swine are reported on hogging-off wheat, vegetable proteins as satisfactory supplements, protein supplements to corn for hogs on pasture, improving a corn-soybean ration for hogs, shrinkage of hogs en route to market, trends in Chicago hog prices, and anemia in pigs.

The sheep studies report information on causes of cull lambs, grain requirements of suckling lambs, and oats for sheep and lambs.

In the poultry work data are reported on the effectiveness of rations composed largely of wheat on young chicks, ground grains in laying mash, and condensed buttermilk for layers; cooperative shipping of eggs; the proportions of meat scrap and dried milk in rations for chicks; liquid and condensed milk for chicks; oats as a substitute for bran and middlings in rations for chicks; protein requirements of growing pullets; confinement v. limited range and grain and mash v. all mash for turkeys; and poultry housing experiments.

Nutrition and other experiments reported data on the chemical and biological evaluation of protein concentrates, a study of the nutritive value and mineral deficiencies of soybeans and soybean products, and determining suitable rations for fattening cattle on the basis of availability and price of feeds.

[Investigations with livestock in Iowa] (*Iowa Sta. Rpt. 1932, pp. 18-24, 26-30, 47, fig. 1*).—In studies with beef cattle results are reported on protein supplements and a simple mineral mixture for fattening calves, by C. C. Culbertson; and the influence of sex upon the quality and palatability of beef from calves and yearlings, by M. D. Helser, Culbertson, B. H. Thomas, and P. M. Nelson.

Swine studies were concerned with the consequences of inbreeding Poland China hogs, by J. L. Lush and Culbertson; outbreeding v. crossbreeding with swine, by P. S. Shearer and Culbertson; the relative efficiency of different sources of calcium for growing and fattening spring pigs in dry lot, by Culbertson and Thomas; swine performance record, by Culbertson, Helser, and Thomas; value of yeast and prepared yeast feeds for fattening pigs on rape pasture, and efficiency of high- and low-protein supplemental feeds for gilts, both by Culbertson; and the relative efficiency of different types of corn for growing and fattening pigs, by Culbertson and J. L. Robinson.

The poultry work included data on the biological value of meat scrap and milk combinations for egg production, and egg yolk and chicken fat as preventives of rickets and slipped tendons of chicks, both by E. W. Henderson; the association of the date of hatch, date of first egg, and maturity with egg production, and the influence of selection and breeding upon egg production and maturity, both by N. F. Waters and Henderson; the effect of inbreeding, linebreeding, outbreeding, and crossbreeding, by Waters and W. V. Lambert; and a comparison of avian growth rates, by Henderson and R. L. Cochran.

Other studies were concerned with inbreeding and other breeding practices used in producing the pure breeds of livestock, by Lush; the preparation of roughages for draft colts, by A. B. Caine; and the development and cure of nutritional anemia in lambs, by Thomas.

[Experiments with livestock] (*New York Cornell Sta. Rpt. 1932, pp. 103, 104, 105, 106-109, 110, 155, 156*).—Nutrition studies have yielded information

on the influence of undigested residues upon the growth and well-being of the animal body, by C. M. McCay, H. Morgan, J. C. Woodward, and S. A. Asdell; the nutritional requirements of trout, by McCay and A. V. Tunison; the vitamin content and protein efficiency of various fish meals, by L. A. Maynard, Tunison, and L. C. Norris; and the nutritive value of proteins of alfalfa and clover hay, by F. B. Morrison, Maynard, and K. L. Turk.

Studies with sheep report data on the relation of feeding and management to the "stiff lamb" trouble, by J. P. Willman, Asdell, W. T. Grams, and W. A. Hagan; the effect of castration and docking upon the gains and the carcasses of male lambs, by R. B. Hinman, Willman, and C. D. Schutt; methods of fattening western lambs, by Willman and Morrison; and a comparison of various instruments for docking lambs, by Willman.

With poultry results are reported on the requirement of chicks for the vitamin G complex, by Norris, A. T. Ringrose, V. Helman, and G. F. Heuser; the calcium requirement of laying hens, by Norris, Heuser, and Ringrose; and the production of clean market eggs, by A. Van Wugenien and A. L. Dean.

Other studies were concerned with the protein requirements of the work horse, by M. W. Harper, and the prevention of anemia in suckling pigs, by Willman, McCay, and B. O. Gormel.

[**Animal husbandry investigations in Ohio**] (*Ohio Sta. Bul.* 516 (1933), pp. 79-81, 82, 83, 84-88, 89, 90, 109, 110, 111, 112).—Preliminary results of studies with sheep are reported on timothy hay in the winter ration of ewes and roughages for fattening lambs, by D. S. Bell, L. E. Thatcher, and C. H. Hunt.

Swine studies include notes on a comparison of ear corn and shelled corn for pigs, grinding oats for pigs, methods of feeding oats to pigs on pasture, finishing limited-fed pigs in dry lot, salmon oil as a source of vitamin D for pigs, and molasses for pigs, all by W. L. Robison; the effect of fluorine on reproduction and lactation in swine, by C. H. Kick and R. M. Bethke; hogging down wheat, by Robison and P. A. Jones; and limitations of soybeans for pigs, by Robison and H. W. Rogers.

The poultry researches offer information on pullets from hen v. pullet eggs, and the effect of management during growth on laying pullets, both by D. C. Kennard and V. D. Chamberlin; the vitamin G requirements of chicks, by Bethke and P. R. Record; nutritional factors affecting the hatchability of eggs, by Bethke, Record, and Kennard; the effect of certain milk rations upon the hydrogen-ion concentration of the intestinal contents of domestic fowls, by [D. W.] Ashcraft; winter eggs from hens, by Kennard and L. A. Malik; and unhulled oats v. oat feed for layers, by Kennard and S. C. Hartman.

Analyses of the vitamin B and G and protein content of alfalfa and timothy hays cut at various stages, by Hunt, Bethke, O. H. M. Wilder, and Bell, are included.

Inspection of commercial feeding stuffs, 1932, T. O. SMITH and S. J. FISHER (*New Hampshire Sta. Bul.* 268 (1932), pp. 48).—The usual report of the guaranteed and found analyses of samples of 283 brands of feeding stuffs collected for official inspection during the year ended June 1932 (E.S.R., 66, p. 762).

Inspection of feeds, W. L. ADAMS and A. S. KNOWLES, JR. (*Rhode Island Sta. Ann. Feed Circ.*, 1932, pp. 12).—This is the usual report of the guaranteed and found analyses of protein and fat of 219 samples of feeding stuffs collected for official inspection in 1931 (E.S.R., 65, p. 553).

Commercial feeding stuffs, September 1, 1931, to August 31, 1932, F. D. FULLER and J. SULLIVAN (*Texas Sta. Bul.* 467 (1932), pp. 222).—This report deals with the chemical analyses and microscopical examination of

2,900 samples of feeding stuffs collected for official inspection (E.S.R., 66, p. 762).

Creep-feeding range calves, J. M. and J. H. JONES (*Texas Sta. Bul.* 470 (1932), pp. 12, figs. 2).—In cooperation with the U.S.D.A. Bureau of Animal Industry a study was undertaken to determine the advisability of creep-feeding calves on Texas ranches. A group of 118 grade Hereford cows and their steer calves were divided into two comparable groups and were placed in separate pastures. The creep-fed lot consisted of 69 calves and their dams, and the average initial weight of the calves was 272.6 lb. During the first 43 days of the test the cows and calves both had access to a grain mixture of ground milo heads and cottonseed meal 4:1. After this period the cows were excluded from the creep. During the second part of the feeding period ground ear corn replaced the milo heads. The calves were fed during the suckling period and for a period of 86 days following weaning. The second lot consisted of 49 calves, averaging 275.4 lb. per head, and their dams.

The creep-fed calves gained 114 lb. more per head during a period of 160 days than did those not creep fed, and after weaning gained 119 lb. more per head in 86 days than did the unfed calves. At weaning time the creep-fed calves were worth 0.5 c. per pound more than the unfed calves and at the end of both feeding periods returned \$3.92 more per head than the unfed calves. The cost per 100 lb. of gain for creep feeding was \$2.36 and \$4.21 during the respective periods. The cows in the creep-fed lot gained 80 lb. per head as compared with 29 lb. per head for the cows in the second group during the suckling period.

Calves from old cows made larger gains in creeps but smaller gains on grass than calves from young cows. Calves that weighed less than 250 lb. initial weight gained 9 lb. more during the suckling period than calves weighing more than 250 lb., but there was no difference in the gains of the two classes during the second part of the feeding period.

Feeding tests and carcass studies with early spring lambs and aged western ewes, A. D. WEBER and W. J. LOEFEL (*Nebraska Sta. Bul.* 276 (1932), pp. 31, figs. 5).—In an effort to determine the minimum amount of grain that may be fed to aged western ewes to produce choice early lambs, three lots of 50 ewes each were fed as follows: (1) A heavy grain ration before and after lambing, (2) no grain before and liberal grain after lambing, and (3) no grain before or after lambing. Approximately the same amount of cottonseed meal and alfalfa was fed in all lots, and corn silage was fed in amounts that the animals would clean up. Ground ear corn was fed at the levels indicated above. The experiment also included a study of the quality and palatability of the carcasses of the ewes fed grain before and after lambing and to determine the effect of weaning on the quality and palatability of lamb carcasses.

The ewes in lot 1 gained 25 lb. more per head before lambing than the ewes in lots 2 and 3, but all lots lost weight after lambing. There were more cases of difficult lambing in lot 1 than in the other lots. The lambs in lot 3 were normal in all respects at birth. There was a distinct relationship between the amount of grain fed to the ewes and the gains made by the lambs before weaning. Only the ewes in lot 1 sold at top prices at the time the lambs were weaned, and the ewes in lot 3 were considerably thinner at weaning time than at lambing time. The results indicate that the condition of the ewes at the close of the breeding season should determine the amount of grain to feed before lambing.

Creep-fed lambs weaned at 3 months of age made good gains when continued on full feed for 28 days. The carcasses of such lambs at weaning time weighed

34 lb. and after an additional 28 days' feeding weighed 41 lb. There was little difference in the two groups in dressing yield or carcass grade, and no noticeable difference in cutting yields. Full feeding for 28 days after weaning slightly increased the yield of internal fat and reduced somewhat the kidney fat, but chemical analyses showed no loss of fat for the entire carcass. The roasts from weanling lambs were a little less pronounced in aroma and flavor of fat and lean but more tender and juicy than roasts from lambs fed for 28 days.

The ewes in lot 1 dressed 50 percent when slaughtered at the time the lambs were weaned. The carcasses of these ewes were graded "good" and were thickly but rather unevenly covered. The flesh from the racks contained 48 percent fat. Roasts from such carcasses had a pronounced but not necessarily an undesirable aroma. When compared with lamb the roasts had a more pronounced and less desirable flavor of both fat and lean, were slightly dry, and not particularly tender.

Fattening lambs in sugar beet districts, W. L. QUAYLE (*Wyoming Sta. Bul. 191* (1932), pp. 43, figs. 4).—Feeding tests were conducted at the Torrington Substation for 7 years and at the Worland Substation for 9 years. At the former place lambs varying in initial weight from 56 to 70 lb. were fed for periods ranging from 80 to 100 days, while at the latter place the lambs varied in weight from 53 to 70 lb. and the feeding periods ranged from 78 to 100 days.

The combined results of these tests showed that the addition of cottonseed cake to a ration of corn and alfalfa increased the rate of gain, but was not usually economical. The same was true when cottonseed cake was added to a ration of barley, wet beet pulp, and alfalfa. The rate of gain was the same when either cottonseed cake or barley was fed with alfalfa, but the cost was higher with the former feed.

Reducing the corn allowance to one fourth and allowing wet beet pulp and alfalfa ad libitum resulted in smaller gains than a full ration of corn and alfalfa. Adding 0.25 lb. of corn to a ration of wet beet pulp and alfalfa increased the rate of gain about 12 percent, but the gain was only slightly better than when the same amount of barley was fed. Adding corn to the above ration produced about four times as many fat lambs as the wet pulp and alfalfa ration alone. When fed with cottonseed cake and alfalfa, both corn and dried beet pulp produced the same gain with practically no difference in feed required per unit of gain. Corn made slightly better gains when fed with alfalfa than with barley, and the latter feed was 87 percent as efficient as the corn. Replacing half the corn with wheat and feeding with cottonseed cake and alfalfa reduced the rate of gain 3 percent and increased the feed required per 100 lb. of gain.

With cottonseed cake and alfalfa, barley produced smaller gains than did corn fed with a similar ration, but, when fed with cottonseed cake, dried beet pulp, and alfalfa, produced the same gain as corn but required more feed to produce a unit of gain. A mixture of barley and wheat fed with cottonseed cake and alfalfa produced faster but less economical gains than the corn and wheat mixture.

Adding dried beet pulp to a ration of corn, cottonseed cake, and alfalfa increased the rate of gain 20 percent and also increased the efficiency of the ration. Dried pulp was but little more valuable than wet pulp when fed with cottonseed cake and alfalfa. Adding wet pulp to a ration of barley, cottonseed cake, and alfalfa increased the rate of gain 20 percent, while dried pulp when added to this ration increased it only 3 percent.

Corn silage did not produce as rapid gains as wet pulp when fed with alfalfa, and neither corn silage nor corn fodder with alfalfa was satisfactory for fattening lambs. Both corn silage and wet pulp improved the palatability and increased the rate of gain when added to a ration of barley and alfalfa. Beet top silage was not so efficient as either corn silage or wet pulp when fed with barley and alfalfa.

Cull beans alone were not so efficient as either equal parts of barley and cull beans or a grain mixture containing 25 percent of cull beans for feeding with alfalfa. Adding sugar beet molasses to either corn or barley and alfalfa improved the palatability and increased the rate of gain. Bean straw and wet pulp produced less rapid and less economical gains than alfalfa and wet pulp. Withholding water from lambs on a ration of wet pulp and alfalfa increased the feed consumption slightly and also the rate of gain as compared with this ration when supplemented with water. Cut alfalfa produced faster gains when fed with wet pulp than did long alfalfa.

[Experiments with sheep in Nevada] (*Nevada Sta. Rpt. 1932, pp. 8, 9*).—Preliminary results of tests to improve wool quality based on selection for quantity and character of fiber are discussed. Some results are also reported on pasture tests with sheep.

Swine performance record—litter comparisons, III, C. C. CULBERTSON, H. H. KILDEE, M. D. HELSER, and W. E. HAMMOND (*Iowa Sta. Leaflet 30 (1933), pp. 8*).—Continuing this study in cooperation with the U.S.D.A. Bureau of Animal Industry (E.S.R., 66, p. 859), data are reported on 17 litters fed during the summer of 1932.

The range in average daily gain per pig was from 1.1 to 1.6 lb., with an average for all litters of 1.3 lb. The feed required to produce 100 lb. of gain varied from 344 to 413 lb., with an average of 376 lb. The average value of all carcass cuts per 100 lb. of live weight ranged from \$8.65 to \$9.31, with an average of \$9.01. The average carcass score of all litters was 86.5, with a range of from 80 to 94 points.

The blood picture of pigs kept under conditions favorable to the production and to the prevention of so-called "anemia of suckling pigs", H. C. H. KERNKAMP (*Minnesota Sta. Tech. Bul. 86 (1932), pp. 32, figs. 4*).—The object of this experiment was to study the factors and conditions under which the symptoms of anemia develop, to collect hematological data on newborn pigs and those in the nursing and early stages of growth, and to determine means of preventing and overcoming the development of the disease. The sows used in the study farrowed their pigs indoors and raised them indoors to about 3 months of age. The pigs were all fed and handled in the same manner, except that some of the sows and litters were kept on concrete floors while others were kept in pens with loam soil floors. The blood of all pigs was examined at regular intervals throughout the experiment.

By excluding baby pigs from all access to soil for at least 5 or 6 weeks beginning at birth, anemia was experimentally produced, while allowing pigs access to soil prevented anemia.

Over 1,100 examinations of the blood of pigs included in this study are reported. While a specific normal range or mean could not be defined on these results, the following ranges are proposed: Birth, 5,500,000 to 7,000,000 erythrocytes, 9,000 to 16,000 leucocytes per cubic millimeter, and 9 to 13 g of hemoglobin per 100 cc of blood; 1 week, 3,000,000 to 4,500,000 erythrocytes, 9,000 to 16,000 leucocytes, and 6 to 9 g of hemoglobin; 2 weeks, where pigs have access to soil or its equivalent from birth, 5,000,000 to 6,500,000 erythrocytes, 9,000 to 16,000 leucocytes, and 7 to 10 g of hemoglobin; 2 weeks, where pigs

do not have access to soil or its equivalent from birth, 2,500,000 to 4,000,000 erythrocytes, 9,000 to 12,000 leucocytes, and 3.5 to 6 g of hemoglobin; 7 to 12 weeks, access to soil or its equivalent, 6,000,000 to 7,000,000 erythrocytes, 14,000 to 20,000 leucocytes, and 9 to 12 g of hemoglobin; and 7 to 9 weeks, no access to soil or its equivalent, 5,000,000 to 6,000,000 erythrocytes, 11,000 to 18,000 leucocytes, and 5.5 to 8 g of hemoglobin.

A marked decrease in the hemoglobin, accompanied by less marked decreases in the erythrocytes, and least marked in the leucocytes, occurred during the first week or 10 days of life of the pig, followed by a corresponding increase in the pigs living under the more natural environment. This change appeared to be physiological. These results show the necessity of making clear the condition or environment of pigs in reporting blood pictures.

At birth polymorphonuclear leucocytes were found in far greater numbers than the lymphocytes, but after 12 days the lymphocytes represented 69 percent of the leucocytes and the polymorphonuclears 28 percent. The relationship was maintained thereafter. Sex apparently played no part in the number of erythrocytes and leucocytes or in the amount of hemoglobin in the blood of young pigs.

Shrinkage of hogs from farm to market by truck and by rail, R. C. ASHBY (*Illinois Sta. Bul. 388 (1933), pp. 557-576, figs. 2*).—Continuing this study (E.S.R., 66, p. 258), the comparisons used were based on 2,084 hogs in 59 consignments, shipped an average of 129 miles by rail, and on 1,252 hogs in 76 consignments, shipped an average of 27 miles by truck.

Of all the consignments fed and watered at market, truck hogs showed less shrinkage than rail hogs whether full-fed at the farm or not. However, hogs trucked more than 55 miles had a larger shrinkage than rail hogs. Truck hogs not fed at the market showed heavier shrinkage than truck hogs fed at market. In both truck and rail consignments some hogs receiving less than a full feed at the farm appeared to shrink less than those full-fed. This was due to the fact that part of the shrinkage occurred before farm weights were taken.

Hogs full-fed at the farm, trucked a short distance but not fed or watered at market, shrank considerably less than rail hogs fed in the same way at the farm, shipped about six times as far, and fed and watered at market. When truck hogs were given less than a full feed at the farm and not fed or watered at market, they showed a heavier shrinkage than rail hogs treated in the same way at the farm but fed and watered at market. Comparable truck and rail consignments from the same farm, but shipped to different markets, showed slight but not significant differences in shrinkage in favor of the rail hogs. Comparable consignments shipped from the University of Illinois to Indianapolis, a distance of 130 miles, showed no significant differences in shrinkage.

The results tend to indicate that on hauls of comparable distances larger shrinkages may be expected on truck hogs than on rail hogs.

Grazing crops for poultry, R. S. DEARSTYNE and P. H. KIME (*North Carolina Sta. Bul. 282 (1933), pp. 12, figs. 7*).—The introduction to this bulletin discusses the vitamin requirements of poultry and the nutrient factors in green feeds.

On the basis of results obtained in experimental work, recommendations are made concerning the essentials of a desirable grazing crop, crops for fall, winter, spring, and summer grazing, and mixed sods of ryegrass and crimson clover.

Growth and development with special reference to domestic animals.—

XXV, The course of energy and nitrogen metabolism in the domestic fowl during 48-day fasts, with special reference to temperament and

training of the birds; notes on 60-day fasts in swine, V. W. PHILLIPS, U. S. ASHWORTH, and S. BRODY (*Missouri Sta. Res. Bul.* 179 (1932), pp. 30, figs. 12).—Continuing this series of studies (E.S.R., 68, p. 508), two yearling White Rock hens were fasted, with sand and water available, until death, and a White Leghorn hen was given 50 g per day of a nitrogen-free diet until death. Their energy metabolism (basal metabolism) was measured by a volumetric and also by Haldane's gravimetric method daily. Their combined urinary and fecal nitrogen and also total creatinine were measured daily.

Mathematical analyses were presented of the time relations of the metabolic and body weight changes. The birds survived for 48, 40, and 23 days and declined in weight from 1,840, 1,974, and 1,982 g to 690, 776, and 1,341 g, respectively. A minimum energy metabolism of about 400 Calories per square meter or about 35 Calories per kilogram was found on the twentieth day of fast in the domestic fowl. The minimum nitrogen excretion was about 165 mg of total nitrogen per day on the twelfth day of fast and about 12 mg of total creatinine per kilogram per day at the same time. The basal metabolism data obtained by the volumetric and gravimetric methods appeared to agree within the limits of experimental error inherent in the subjects. The results obtained with a bird habituated to laboratory life gave the most consistent results, and this bird also survived longest.

Similar analyses of published fasting data of humans and dogs are presented, and the results are compared with those obtained with poultry. Some striking differences were noted. Data are also presented by S. R. Johnson on the energy and nitrogen metabolism of two sows during fasts of about 2 months' duration.

The quantities of vitamin A required by pullets for maintenance and for egg production, R. M. SHERWOOD and G. S. FRAPS (*Texas Sta. Bul.* 468 (1932), pp. 19, figs. 4).—White Leghorn pullets that had been raised on a standard ration, including free access to green feed, were divided into three lots of 35 birds each and were fed from October 15 to April 30. The birds were confined in pens having cement floors. Lot 1 received a mash containing 20 percent of yellow corn and scratch grain consisting of yellow corn. This group was calculated to receive an average of 270 units of vitamin A. Lot 2 was fed mash containing 10 percent each of yellow and white corn and scratch grain made up of equal parts of yellow and white corn. This group received an average of 120 units of vitamin A. The third lot received white corn only.

The birds in lot 1 were heaviest in weight and had laid the most eggs at the end of the experiment. In lot 2 the birds averaged slightly less in weight than those in lot 1 and had laid about 17 percent fewer eggs. The average weight of the birds in lot 3 was decidedly smaller than in the other groups, and they had laid appreciably fewer eggs. The birds in this last group lived from 34 to over 199 days and showed wide variations in the amount of vitamin A stored in their bodies. In all groups the vitamin A content of the eggs decreased from about 20 units per gram of yolk at the beginning to from 5 to 8 units at the end of the experiment.

From the data it was calculated that for only one unit of vitamin A in the egg, it required 6.3 units in the feed in addition to the maintenance requirements. For a pullet weighing 3.2 lb. the maintenance requirement was estimated at 105 units per day. Mash containing 8 percent of alfalfa meal furnished only 30 to 40 units of vitamin A per day. Heat-dried alfalfa containing 100 units per gram fed with yellow corn did not supply sufficient vitamin A to maintain high production and high vitamin A potency of the eggs, and

laying pullets apparently required green feed to provide sufficient vitamin A to maintain this standard.

Production and hatchability of eggs as affected by different kinds and quantities of proteins in the diet of laying hens, T. C. BYERLY, H. W. TITUS, and N. R. ELLIS (*Jour. Agr. Res.* [U.S.], 46 (1933), No. 1, pp. 1-22, figs. 4).—Single Comb Rhode Island Red pullets were divided into two series of pens, nine pens in each series, in a study by the U.S.D.A. Bureau of Animal Industry. In the first series each pen contained 25 pullets, while in the second series there were 15 pullets per pen. Cockerels were transferred from one pen to the next every day. The pullets were confined and all received the same basal diet. The following proteins were fed to comprise from 11.2 to 23.6 percent of the diet: Desiccated meat meal, crab scrap meal, North Atlantic fish meal, dried buttermilk, dried yeast preparation, soybean meal, cottonseed meal, and a combination of meat meal, fish meal, and buttermilk.

The feed consumption in the check lot was practically the same as in the supplemented lots, but the egg production was low and the hatchability only fair. All of the supplements, except cottonseed meal and yeast preparation, gave good egg production, and the buttermilk supplement proved to be excellent for winter egg production. Cottonseed meal delayed the beginning of egg production, increased the incidence of chondrodystrophy in the eggs of certain hens, and gave low hatchability. The egg production on the yeast diet was not so good as that on the basal diet. In the lots receiving North Atlantic fish meal and soybean meal hatchability was low, and in the case of the latter supplement the incidence of chondrodystrophy in the eggs of certain hens was augmented.

Increasing the percentage of protein in the diet within the limits defined in this study, increased egg production by increasing the intensity, by increasing egg weight through direct effect on yolk weight, and by increasing body and yolk weight increased the albumen weight. The increased protein level had a favorable effect on the quantity of egg produced per unit weight of feed eaten but decreased the efficiency of proteins for egg production. In general, more eggs were hatchable from hens which laid intensely than from those which did not.

Proteins of vegetable sources increased the incidence of chondrodystrophy only in the embryos of hens likely to produce such embryos. The embryos of eggs from hens on diets containing vegetable proteins had a high second-week mortality.

Hereditary and environmental factors affecting variability in egg production, F. A. HAYS (*Massachusetts Sta. Bul.* 289 (1932), pp. 12, figs. 4).—This study was undertaken to determine variability of inherited characters affecting fecundity and also the effect of some environmental influences upon variability in egg production. Three lines of breeding were established by selecting for (1) uniformity in inherited characters affecting fecundity, (2) uniformity of annual egg records, and (3) high annual records. Each of these lines was carried through four generations.

The age at sexual maturity showed a coefficient of variation of about 10 percent brought about by environment in birds of the same genetic constitution for sexual maturity. Winter intensity was highly variable, due to genetic differences, but this variation was reduced by selection through the four generations. There were no indications that environment influenced clutch size. The length of winter pause could be reduced by constant selection, but it was also affected by environmental influences. There was evidence that broodiness as measured by total days broody was influenced by hereditary

modifiers. Persistency showed a variation of about 10 percent that was ascribed to environmental factors.

Variability in winter egg production decreased in the third line of breeding only, and increased inbreeding in successive generations did not reduce variations in winter egg records. Variations in annual egg production were less in the second and third lines of breeding than in the first. About 7 percent of the variation in annual production was due to differences in hatching dates. Annual egg records were not affected by increases or decreases in body weight of pullets during the laying year. Egg production was reduced by house temperatures near the freezing point or by temperatures above 70° to 75° F., and changes in production usually followed soon after temperature changes.

Costs of producing broilers and pullets in 1932, K. T. WRIGHT (*Michigan Sta. Quart. Bul.*, 15 (1933), No. 3, pp. 153-156, fig. 1).—An analysis of 48 detailed records of baby chicks showed that at 12 weeks of age the average cost was 27 c. per bird. About one third of the cost was the initial price of the chick, one third went for feed, and one third for labor, equipment, and other costs. The average weight at 12 weeks was 1.8 lb. per bird, which made the cost of raising 15.3 c. per pound. The 10 lowest records had an average production cost of 11 c. per pound, while the 10 highest records averaged 23 c. per pound. The low-cost group had an average mortality of 11 percent in 12 weeks, while the other group had 20 percent. The former group ate 3.2 lb. of feed to produce 1 lb. of poultry, while the latter group consumed 4.9 lb. of feed.

In analyzing 51 records for 24 weeks, it was found that out of every 100 chicks started 44 broilers were sold or used and 40 pullets were saved. These pullets weighed 3.4 lb. each at 24 weeks. The average cost of the pullets was 53 c., of which 43 percent went for feed, 23 percent for baby chicks, 14 percent for labor, and 20 percent for other costs. It required over 18 lb. of feed to grow each pullet. One third of the group had a mortality of less than 10 percent and the average cost of their pullets was 48 c., while another one third lost over 20 percent of their chicks and their pullets cost 57 c. each. The most efficient producers used 3.5 lb. of feed per pound of poultry produced, while the least efficient group used 7.1 lb. of feed.

Raising chicks in 1933, D. C. KENNARD (*Ohio Sta. Bimo. Bul.*, 18 (1933), No. 2, pp. 42-47, figs. 2).—Practical recommendations and information on raising chicks are presented to assist those inexperienced in poultry production to avoid some of the frequent causes of failure and possibly to serve the more experienced producer.

DAIRY FARMING—DAIRYING

[Investigations with dairy cattle and dairy products in California] (*California Sta. Rpt. 1932*, pp. 9-13).—Studies with dairy cattle have yielded information on the sanitary care, operation, and installation of milking machines; "cardboard" flavor in milk; feed flavors in milk; effect of temperature and humidity on milk production; effect of fly sprays on cows; the feasibility of raising dairy calves without roughage; and the lower total digestible nutrients from a given area of land when utilized for Sudan grass than as alfalfa pasture.

In dairying data are reported on the effect of variations in speed of cream separators upon fat test of cream, effect of different methods of cooling pasteurized cream upon its consistency and whipping quality, the cause of and remedy for sticky, crumbly butter resulting from winter feeding, a com-

parison of the efficiency and capacity of different types of milk pumps, the value of internal-tube milk coolers, effect of fast freezing on the texture of ice cream, effect of stabilizers on the body of sherbets and ices, the use of honey in ice cream, and the effect of the type of milk curd in infant feeding.

[**Studies with dairy cattle in Delaware**] (*Delaware Sta. Bul. 179 (1932), pp. 21, 23*).—These studies have produced information regarding the relation of the alcohol-milk test to pregnancy in cattle, by C. C. Palmer, and powdered skim milk for dairy calves and dried tomato pomace in the dairy ration, both by A. E. Tomhave.

[**Investigations with dairy cattle and dairy products in Indiana**] (*Indiana Sta. Rpt. 1932, pp. 29-33, 52, 53, figs. 2*).—Studies with dairy cattle yielded information on supplementing soybean hay with and without high protein concentrates, suitability of different varieties of soybeans for hay, chemical and physical effects of soybean feeding on the commercial value of milk and butterfat, the value of grinding grains for growing dairy heifers, the vitamin A content of butterfat from the Guernsey and Ayrshire breeds and from cows under different conditions of feeding, vitamin A value of alfalfa hay cut at different stages of maturity, and soybean hay as a good source of vitamin A.

Dairy products studies included investigations of factors affecting body, texture, and quality of ice cream; enzymes in sweet and sour farm-skimmed cream as related to the keeping qualities of butter; methods used in washing milking machines and their comparative value; chemical and physical effects of heavy soybean feeding on milk and butterfat production; the effect of hydrogen-ion concentration and season of the year upon the keeping qualities of butter; marketing of cream and milk; measuring the vitamin A value of butter by its natural color; and maintaining the vitamin A value of butter by proper feeding.

[**Investigations with dairy cattle and dairy products in Iowa**] (*Iowa Sta. Rpt. 1932, pp. 18, 25, 26, 49-54*).—Dairy cattle studies report data on the consequences of inbreeding in Holstein-Friesian cattle, by J. L. Lush and C. Y. Cannon; the comparative efficiencies of a modified silage cutter and a hay fork for storing hay, by Cannon, E. N. Hansen, and E. V. Collins; and a study of fly sprays, by Cannon and C. H. Richardson.

With dairy products, studies have been conducted on the influence of the physical properties of milk on its rate of digestion in vivo, by Cannon and D. L. Espe; the influence of the acidity in cream on fat losses in buttermilk, and the effect of lipins and of sulfonation of unsaturated fats on certain modified Babcock tests of fat in buttermilk, both by E. W. Bird; standardization of Iowa butter, by M. Mortensen; the significance of numbers and types of bacteria in butter from the standpoint of its keeping quality, development of a method for the direct microscopic examination of butter, the bacterial efficiencies secured in pasteurizing milk from individual farms, an organism causing rancidity in butter, micro-organisms causing surface taint in butter, an unusual type of coagulation in evaporated milk, *Bacillus coagulans* as the cause of coagulation in evaporated milk, the germicidal property of milk, pasteurization efficiency and subsequent contamination in Iowa market milk plants, classification of the organisms important in dairy products, development of butter cultures from mixtures of organisms, the products formed by *Streptococcus citrovorus* and *S. paracitrovorus* from citric acid and from lactic acid, methods of preparing butter cultures for mail shipment, types and sources of "pin point" bacteria in ice cream, bacterial standard for Iowa ice cream, and churn sanitation, all by B. W. Hammer.

[**Experiments with dairy cattle at the New York Cornell Station**] (*New York Cornell Sta. Rpt. 1932, pp. 99, 100, 101, 103*).—In studies with dairy cows data are reported on the minimum amount of protein for dairy cows, by E. S. Savage, E. S. Harrison, and S. H. Work; raising dairy calves on dry concentrate mixtures, by Savage, Harrison, and C. H. Crawford; and fatty compounds in the blood of lactating and of dry cows, by L. A. Maynard, C. M. McCay, P. J. Schaible, K. L. Turk, and Work.

[**Investigations with dairy cattle and with milk in Ohio**] (*Ohio Sta. Bul. 516 (1933), pp. 68-76*).—Results of experiments with dairy cattle are reported on feeding wheat to dairy cows, by C. F. Monroe, C. C. Hayden, and C. E. Knoop; the relative feeding value of ground soybeans and soybean oil meal, by A. E. Perkins, M. A. Bachtell, and W. E. Weaver; dairy feeds which tend to cause acidosis, by Perkins and Monroe; value of Manamar for growth and milk production, by Monroe and W. E. Krauss; soluble blood flour v. skim milk powder for calves and the vitamin A content of corpora lutea from cows, by Krauss, Monroe, and Hayden.

The milk studies include results on the composition of milk as affected by the amount of protein fed, by Perkins; raw v. pasteurized milk, by Krauss and R. G. Washburn; the value of copper and iron supplements in an exclusive milk diet for dairy calves, by Knoop and Krauss; the effect of the addition of small quantities of iodine to milk on the rate of bacterial growth, by T. S. Sutton, Krauss, and Bohn; the effect of avitaminosis A on the nervous system of the white rat, by Sutton, H. E. Settersfield, and Krauss; increasing the vitamin D content of the milk, by Krauss and R. M. Bethke; and the effect of feeding yeast to cows on the vitamin B and vitamin G content of milk, by Krauss and C. H. Hunt.

Two systems of feeding dairy cows: High roughage and low grain versus low roughage and high grain, J. B. LINDSEY and J. G. ARCHIBALD (*Massachusetts Sta. Bul. 291 (1932), pp. 15*).—Continuing this study (E.S.R., 65, p. 370), over a period of 3.5 years, the high roughage group was fed approximately 1 lb. of grain for each 4.5 lb. of milk produced, 35 lb. of silage, and as much hay as they would clean up. The low roughage group received approximately 1 lb. of grain for each 2.5 lb. of milk, 20 lb. of silage, and hay as above mentioned.

The cows in lot 2 maintained their general appearance somewhat better and made slightly larger gains in weight than those in lot 1. In the latter group the cows tended to be thinner and more rough-coated. Lot 2 produced more milk on a daily and yearly basis and, while their lactation periods were shorter, their dry periods were also shorter than those in lot 1. In lot 2 the cows required 7 percent less dry matter and 2.7 percent less digestible nutrients to produce 100 lb. of milk. The feed cost of milk production was practically the same for both groups, but the high roughage method of feeding involved a smaller cash outlay. The cows in the low roughage group maintained their milk production from year to year better than those in the high roughage group. In lot 1 the cows showed a decline in milk test as compared with the tests previous to the start of the experiment. Group 2 was nearer normal in reproductive function than group 1.

Pasturing Sudan grass at Wooster, C. F. MONROE and C. C. HAYDEN (*Ohio Sta. Bimo. Bul., 18 (1933), No. 2, pp. 34-36, fig. 1*).—The results of a test with Sudan grass pasture for three liberally milking cows, when calculated to an acre basis, showed a total production for 129 days of 11,154 lb. of milk and 362 lb. of butterfat. Also 1 acre of Sudan grass would furnish 215 cow-pasture days. Chemical analyses of the grass cut at three different dates showed

that the protein content on an air-dry basis varied from 18.2 to 23.4 percent. The precautions that must be taken in using Sudan grass for pasture are pointed out.

Sorghum silage as a source of vitamin A for dairy cows, O. C. COPELAND and G. S. FRAPS (*Texas Sta. Bul. 473 (1932), pp. 12, fig. 1*).—A group of five Jersey cows was fed in dry lot on a ration of cottonseed meal, sorghum silage, and cottonseed hulls ad libitum. To the cottonseed meal was added 2.5 percent of limestone and 1 percent of salt, and the mixture was fed at the rate of 1 lb. for each 2.25 lb. of milk produced daily. The silage contained about 5 units of vitamin A per gram and was the principal source of this vitamin in the ration, another group was fed cottonseed meal and hulls only, while a third group had access to pasture in addition to meal, hulls, and silage.

In the first group the butterfat contained from 2 to 12 units of vitamin A per gram, the fat of the second group averaged 2.5 units, while that from cows in the third group contained as much as 33 units. The cows in group 1 produced fat containing an average of 1,960 units; those in group 2 averaged 340 units; and those in group 3 averaged 17,280 units per day. These results showed that unless supplemented with pasture the ration did not supply sufficient vitamin A to produce butterfat of high potency in vitamin A.

After prolonged feeding on cottonseed meal and hulls the cows became very weak. Two of them were cured by administering cod-liver oil, and one by feeding fresh green grass. It was evident that the animals were suffering from a deficiency of vitamin A, which the ration did not supply. The cows in the first group showed symptoms of night blindness and other disorders, indicating that the ration lacked sufficient vitamin A for good health. It was estimated that cows on sorghum silage consumed about 106,000 units of vitamin A daily and returned only about 1,960 units per day in the butterfat, which was low in this vitamin. These results indicate that the dairy cow has a high daily requirement for vitamin A, either because of the destruction of the vitamin during the digestion process or because of the high maintenance requirement during lactation, or both.

The effect of milk foam on dairy calves, T. M. OLSON (*South Dakota Sta. Bul. 273 (1932), pp. 8*).—To determine the effect of milk foam on the growth of calves, two lots of three calves each were fed the same basal ration. In addition one lot received a definite amount of skim milk direct from the separator, while the other lot received an equal weight of skim milk and foam. The amount of foam consumed by the latter lot was approximately twice what would normally collect on the quantity of milk received. The calves were weighed at 10-day intervals and were measured for height at withers at 30-day intervals. Two trials were conducted with calves that were rather old when started on the experiment, while a third test was conducted with calves 3 weeks old.

There was no significant difference in the increase in weight or height at withers of calves fed skim milk and of those fed skim milk and foam. The calves receiving foam tended to bloat slightly at times, but no bad after effects were noted. The hair of calves receiving foam was sometimes rough, indicating a lowered physical condition. The results as a whole indicated that feeding the foam that normally collects on skim milk is a safe practice when the amount fed is given in definite quantities, and that any digestive troubles that occur are due to improper feeding and not to the foam itself.

Normal growth in dairy cattle, D. L. ESPE, C. Y. CANNON, and E. N. HANSEN (*Iowa Sta. Res. Bul. 154 (1932), pp. 297-319, figs. 4*).—This study was based on growth in live weight and in skeletal development of dairy cattle in the

station herd in order to contribute to the present information on normal growth in dairy cattle.

The male calves of the breeds studied weighed more at birth than the female calves. The average birth weights of female calves were for Holsteins 89 lb., Guernseys 65, Ayrshires 63, and Jerseys 50 lb., and for males 99, 69, 71, and 54 lb. The coefficients of variation in live weight among individuals ranged from 15 percent in calves to less than 10 percent in 2-year-olds. The time of first freshening marked the greatest change in the rate of growth in live weight. The animals of the different breeds approached mature size at about the same relative rate. Mature growth values were approached most rapidly in height at withers. Holsteins, Ayrshires, and Jerseys were wider in relation to depth than Guernseys. The average mature weight in this herd was Holsteins 1,405 lb., Ayrshires 1,111, Guernseys 1,072, and Jerseys 950 lb. Gestation and lactation had considerable influence on live weight. Late-freshening heifers weighed more than heifers calving at the usual time, but after freshening the weights in both groups were quite comparable.

Selecting sires by progeny to maintain butterfat level, A. C. BALTZER (*Michigan Sta. Quart. Bul.*, 15 (1933), No. 3, pp. 143-146, fig. 1).—An analysis of the level of production of the dams and their daughters by 204 bulls of the Holstein, Jersey, and Guernsey breeds showed that the progeny of a sire was a better basis for selection than type or ancestry performance records. It was also revealed that the ability to transmit higher butterfat production appeared to exert itself somewhat stronger within the Jersey breed than within other breeds. The inheritance factor varied more within the individuals of a breed than between the best transmitting bulls of the different breeds.

The chemical composition and nutritive properties of milk as affected by the level of protein feeding, I, II (*Ohio Sta. Bul.* 515 (1932), pp. 69, figs. 4).—The results of the experiments here published are divided into two parts.

I. Chemical composition, A. E. Perkins (pp. 3-44).—In conjunction with studies previously noted (E.S.R., 51, p. 875), analyses were made of several hundred samples of milk according to the protein content of the ration fed the cows. The analyses showed that even at the greatest practical extremes in the level of protein feeding the only variation which was consistent and progressive from group to group was the percentage of residual or nonprotein nitrogen, which increased in amount as the level of protein feeding increased. The urea portion of the nonprotein nitrogen increased eight times from the lowest to the highest level of protein feeding. Amino nitrogen and creatine-creatinine nitrogen were also apparently affected to a lesser extent. On a dry matter basis the proportion of protein in the dry matter increased sufficiently to account for the observed increase in nonprotein nitrogen.

The increase in nonprotein nitrogen appeared to be coupled with a slight increase in the proportion of albumin at the highest level of protein feeding. Together these resulted in lowering by about 6 percent the proportion of total nitrogen which appeared in the form of casein.

A careful analysis of the data did not confirm a tentative conclusion previously made that the low protein ration had a slightly depressing effect on the fat content of the milk. The character of the fat was apparently unaffected by the level of protein feeding. The results seem to justify the conclusion that no changes of major importance may be expected in the composition of milk from relatively small variations in the level of protein feeding.

II. Nutritive properties, W. E. Krauss and C. C. Hayden (pp. 45-69).—The food values of milk produced by some cows described in part 1 on rations

of extremely high protein, extremely low protein, or normal protein contents were compared. Determinations for vitamins A, B (complex), and D, total nutritive value, and biological value of the proteins were made with rats, and a practical feeding trial with heifer calves was also conducted.

While slight differences were found in the vitamin A and D contents of the three kinds of milk, the differences could be traced to variations in these vitamins in the rations fed. Enough difference was found in the vitamin B (complex) content to indicate that some relationship existed between the level of protein feeding and the amount of vitamin B (complex) in the milk. A ration deficient in the vitamin B (complex) required 15 cc of "normal milk", 16 cc of "high protein milk", and 20 cc of "low protein milk" to allow normal growth. No difference was found in the total nutritive effect of the milks, based on the method of exclusive milk feeding, or in the biological value of the milk proteins, based on gain per gram of protein intake. With calves there was no significant difference in the rates of gain when any of the three milks were fed as part of the practical ration.

Studies on the nutritive value of milk.—II, The effect of pasteurization on some of the nutritive properties of milk, W. E. KRAUSS, J. H. ERB, and R. G. WASHBURN (*Ohio Sta. Bul. 518 (1933), pp. 33, figs. 8*).—Continuing this study (E.S.R., 65, p. 892), milk from cows receiving a ration of alfalfa hay, corn silage or soaked beet pulp, and a grain mixture of corn, oats, bran, and linseed meal was sampled twice weekly and divided into two parts. One sample was held in a cooler at from 40° to 45° F., while the other sample was "laboratory pasteurized" in a closed glass container at 145° F. (62.7° C.) for 30 minutes. Other samples of milk were pasteurized in the usual commercial manner. A total of 32 pairs of albino rats were fed so that one of each pair received raw milk exclusively and the other pasteurized milk exclusively.

The rats developed nutritional anemia at about the same rate upon the basis of hemoglobin determinations and red cell counts on either raw or pasteurized milk. Copper and iron determinations showed no loss of these elements when milk was heated to 145° F. in a closed vessel for 30 minutes or when it was pasteurized under commercial conditions. When the anemia factor was eliminated by adding copper and iron to the milk fed, there was no significant difference in the total growth of rats fed raw or pasteurized milk exclusively over a 12-week period. No difference was found in the ash of the femurs and entire bodies or in the calcium and phosphorus content of the entire bodies of rats fed exclusively on one or the other of these milks. Heating milk in the closed glass container did not affect vitamins A, G, and D, but did destroy at least 25 percent of the vitamin B in the original raw milk. Using the Hill technic (E.S.R., 51, p. 379), 24 samples of the milk were tested for hardness of curd, and the results indicated that curd tension was slightly reduced by pasteurization. It is concluded that the nutritive deficiencies of pasteurized milk may readily be overcome by proper dietary control so that its continued use offers no serious problem.

The application of a yeast extract medium to a test for determining quality of milk, E. D. DEVEREUX (*Amer. Jour. Pub. Health, 22 (1932), No. 12, pp. 1291-1293; abs. in Michigan Sta. Quart. Bul., 15 (1933), No. 3, p. 208*).—At the Michigan Experiment Station an attempt was made to shorten the incubation period or improve the efficiency of the Cooledge test (E.S.R., 46, p. 479). By changing the formula of the medium used the correlation coefficient between the test and the actual keeping quality of the milk was increased from +0.75 or +0.77 to +0.86±0.02. This was also an increase in the accuracy over the methylene blue reduction test. The new medium permitted

earlier detection of milk of pure quality and did not require the attention of the operator in most cases for 6 hours after the tubes were inoculated. Because of its high degree of accuracy and applicability the test may be used to determine the quality of other dairy products.

A yeast extract medium for the examination of milk, E. D. DEVEREUX (*Amer. Jour. Pub. Health*, 22 (1932), No. 12, pp. 1293, 1294; *abs. in Michigan Sta. Quart. Bul.*, 15 (1933), No. 3, p. 206).—The yeast extract broth used in the above study had the following formula: Yeast extract (Difco), 5 g; peptonized milk (Difco), 10 g; salt, 5 g; dextrose, 10 g; and water, 1,000 cc. This broth was adjusted to pH 7, autoclaved for 15 minutes at 15 lb. pressure, and 15 g of washed agar was added to each liter of broth.

The relationship of acetylmethylcarbinol and diacetyl to butter cultures, M. B. MICHAELIAN, R. S. FARMER, and B. W. HAMMER (*Iowa Sta. Res. Bul.* 155 (1933), pp. 321-360).—The results obtained in these studies are reported under the following headings: (1) Acetylmethylcarbinol and diacetyl in butter cultures, (2) sources of acetylmethylcarbinol and diacetyl in butter cultures, (3) destruction of acetylmethylcarbinol and diacetyl by the butter culture organisms, and (4) development of a special butter culture.

It was found that butter cultures having a satisfactory flavor and aroma contained considerable amounts of these compounds, but cultures lacking in these qualities contained little or none. From a quantitative standpoint the carbinol was more important than the diacetyl. A culture containing only a small amount of these compounds showed few of the citric acid fermenting streptococci normally present in considerable numbers. In the early stages of ripening of satisfactory cultures only small amounts of compounds were present, but in later stages there was a material increase in the compounds, generally accompanied by a pronounced increase in volatile acid. Holding cultures for long periods at 21° C. sometimes caused a definite decrease in the compounds, but a decrease in the volatile acids did not occur.

Comparatively few of the *Streptococcus lactis* strains and only a small number of the citric acid fermenting streptococci produced these compounds in milk. With *S. lactis* more of the compounds were produced when milk was modified by adding 0.1 or 0.3 percent of acetic acid or 0.03 percent of acetaldehyde than when it was not modified. With the citric acid fermenters the amount of the compounds produced was small, but the addition of citric acid in certain concentrations, either alone or in combination with another acid, commonly increased the production of these compounds. Adding lactic or sulfuric acid to milk did not influence the production of these compounds or of volatile acids, but the addition of citric acid increased both.

The compounds were destroyed by citric acid fermenters in a pasteurized mixture of milk and butter culture and also in milk that was pasteurized after ripening to various acidities, and the destruction was conspicuous at comparatively low acidities. When the culture was neutralized and held at a temperature favorable for the growth of the organisms contained, there was a pronounced decrease in the compounds, and in cultures where the compounds had decreased they were greatly increased by the addition of citric acid. Repeated neutralization of a culture resulted in a complete disappearance of the compounds.

In a special butter culture the production of the compounds was very rapid, and at the end of a holding period of from 15 to 24 hours at 21° C. the amounts present were usually larger than the amounts present in regular cultures, and considerable volatile acid was produced. Additional holding usually resulted in a decrease in the compounds. During the period when the compounds were

being produced rapidly there was a decrease in the acidity of the culture. The production of the compounds was more rapid at from pH 4 to 4.3, although they were produced over a range of from pH 3.1 to 4.6 with the strain of citric acid fermenting streptococci used.

Eighteenth annual report of the creamery license division, T. H. BINNEY (*Indiana Sta. Circ. 194* (1932), pp. 16, fig. 1).—This is the usual report of the State creamery license division for the year ended March 31, 1932 (E.S.R., 66, p. 570). It deals with the comparative annual production of dairy products in Indiana, the creamery inspection, and the examination of testers.

VETERINARY MEDICINE

[Work in animal pathology in California] (*California Sta. Rpt. 1932*, pp. 16-18).—Brief references are made to the progress of work (E.S.R., 67, p. 595) with Bang's disease in cattle and swine, tuberculosis in cattle and the B.C.G. culture, anaplasmosis of cattle, brain disease of horses and mules (E.S.R., 66, p. 76), polyarthrititis infection in sheep, laryngotracheitis, pullorum disease, fowl pox vaccine, fowl cholera in turkeys, poisoning of young turkeys by ashes of eucalyptus wood, and inflammation of sinuses and respiratory disturbances of turkeys.

[Report of work with diseases of livestock in Indiana] (*Indiana Sta. Rpt. 1932*, pp. 60-62).—A brief account is given of the work of the year (E.S.R., 67, p. 596), including a study of immunity in heifers injected with living cultures of *Brucella abortus* during calfhood; infectious abortion, enteritis, and colitis in pigs; the occurrence of *Salmonella suispestifer* in pigs; treatment of lambs for stomach worms; agglutination tests for Bang's disease in cattle, infectious abortion in hogs and mares, pullorum disease in poultry, and *Brucella* infection in goats; autopsies of poultry, hogs, sheep, etc.; a disease affecting the fore limbs of cattle; and leg weakness in chicks.

[Work with diseases of poultry, etc., in Iowa] (*Iowa Sta. Rpt. 1932*, pp. 30, 31, 90-92).—The work of the year briefly referred to (E.S.R., 67, p. 450) includes that with tracheitis in poultry, range paralysis in chickens, the influence of various nutritional factors on blindness and range paralysis in chickens, and the egg as a possible mode of transmission of range paralysis in chickens, all by C. Murray, F. D. Patterson, H. L. Wilcke, and E. W. Henderson; the influence of protein levels and calcium and phosphorus balance upon rachitis of chicks, by Henderson, Wilcke, and Murray; breeding for resistance to fowl typhoid in poultry, by W. V. Lambert and N. F. Waters; and genetic investigation of resistance and susceptibility to disease in laboratory animals, by Lambert.

[Report of work in animal pathology and parasitology in Ohio] (*Ohio Sta. Bul. 516* (1933), pp. 78, 79, 81, 83, 84, 88, 89).—Results of the work of the year (E.S.R., 67, p. 69) are briefly noted under the headings of *Brucella abortus* infection in cattle and the presence of *B. abortus* in the udder of cows and its relationship to agglutinins in the milk and blood, both by B. H. Edgington and A. Broerman; nodular formation by the larvae of *Oesophagostomum columbianum* and longevity of *O. columbianum* larvae, both by R. E. Rebrassier; swine erysipelas, by [A. F.] Schalk; January-hatched chicks less subject to coccidiosis and vices, by D. C. Kennard and V. D. Chamberlin; and immunization of chickens against fowl pox by the use of pigeon pox virus and fowl or range paralysis, both by Edgington and Broerman.

[The second report of the director of the Institute of Animal Pathology, University of Cambridge, 1931] (*Cambridge Univ., Inst. Anim. Path. Rpt.*

Dir., 2 (1931), pp. V+222, pls. 11, figs. 25).—The contributions here presented (E.S.R., 66, p. 866) are as follows: Immunisation of the Fowl and the Pigeon against Epithelioma Contagiosum, by R. E. Glover (pp. 1-20) (see p. 112); The Dublin Type of *Salmonella* as a Cause of Disease in Calves, by T. J. Bosworth and R. Lovell (pp. 21-27); The Use of B.C.G. in the Vaccination of Calves against Tuberculosis, by J. B. Buxton and A. S. Griffith (pp. 28-45); Further Results of Immunity Experiments on Calves with the B.C.G. Vaccine, by A. S. Griffith, J. B. Buxton, and R. E. Glover (pp. 46-52); Observations on the Classification of *Bacillus welchii*, by A. J. Wilsdon (pp. 53-85); Some Biochemical Studies on the Blood of Sheep (pp. 86-120) and The Effects of Feeding Mineral Supplements on the Chemical Content of the Blood of Sheep (pp. 121-133), both by G. D. Shearer and J. Stewart; The Effect on the Iodine Content of (1) the Thyroid Glands and (2) the Blood of Wethers and Ewes When Dosed with Potassium Iodide, by M. C. Franklin (pp. 134-142); Vitamin C Requirements of the Dog—Attempts to Produce Experimental Scurvy, by J. R. M. Innes (pp. 143-150); The Mode of Action of Vitamin D, by L. J. Harris and J. R. M. Innes (pp. 151-174) (E.S.R., 65, p. 896); A Preliminary Note on "Blood Tumours" (Haemangio-Endotheliomata) in the Fowl, by F. Blakemore and J. R. M. Innes (pp. 175-183); The Relationship of Glycerine in Veal Broth to the Potency of Tuberculin, by H. R. Allen (pp. 184-193); A Note on *Simulium* sp. Attacking Horses and Cattle in Herefordshire (pp. 194-197), Some Nematode Parasites of the British Fallow Deer (*Dama dama*) (pp. 198, 199), and A List of Parasites Examined during the Year (pp. 200-203), all by J. S. Steward; and Experiments on the Treatment of Parasitic Gastro-enteritis in Sheep and Lambs (pp. 204-212), Some Notes on the Treatment of Equine Strongylosis with Oil of Chenopodium (pp. 213-219), and A Note on the Size of the Eggs of Some Species of Sheep Worms (pp. 220-222), all by W. A. Wood.

Original contributions from the Mukden Institute for Infectious Diseases of Animals (*Mukden Inst. Infect. Diseases Anim., Orig. Contrib.*, 2 (1932), pp. [3]+2+268, pls. 14, figs. 17; *Eng. abs.*, pp. 231-268).—These contributions on animal pathology, in Japanese, with English abstracts, have all been previously noted from other sources except On the Duration of the Existence of Rinderpest Virus in the Body of Immunized Cattle after Inoculation with the Highly Virulent Virus, by T. Inoue and R. Shimizu (pp. 161-166, 255).

Report of the parasitologist, H. L. VAN VOLKENBERG (*Puerto Rico Sta. Rpt.* 1932, pp. 21-23).—In this report of the status of parasites in Puerto Rico (E.S.R., 67, p. 597), nodular worms and stomach worms of cattle and the tapeworm *Moniezia expansa* of cattle and goats are considered.

Microscopic diagnosis of parasitism in domestic animals (*Illinois Sta. Cir.* 401 (1933), pp. 67, figs. 89).—This is an illustrated account of the technic employed in the detection of parasites in domestic animals.

Tests of the efficacy of single treatments with tracheal brushes in the mechanical removal of lungworms from foxes, K. B. HANSON (*Jour. Amer. Vet. Med. Assoc.*, 82 (1933), No. 1, pp. 12-31, figs. 7).—In critical tests made to determine the efficacy of two types of tracheal brushes in the treatment of foxes for lungworms of the species *Eucoleus acrophilus* Crep. and *Crenosoma vulpis* Crep., the homemade type rated slightly higher than the tracheal swab syringe, largely due to the fact that the swab syringe failed to reach to the bottom of the trachea in long rangy foxes. It is concluded that the tracheal brush treatment is relatively safe and harmless when performed with proper care and judgment. The average efficacies against tracheal infestation in the arbitrary groups, in percentages, were 70.48, 80, 82.86, 87.96, and 95.19, respectively, for

Eucoleus, and 100, 0, and 66.67, respectively, for *Crenosoma*. The average efficacies against the entire *Eucoleus* infestation in the arbitrary groups, in percentages, were 52.86, 60.18, 38.41, 53.67, and 29.57.

N-butylidene chloride, a new anthelmintic, W. H. WRIGHT, J. BOZICEVICH, P. C. UNDERWOOD, and J. M. SCHAFER (*Vet. Med.*, 28 (1933), No. 2, pp. 52-64).—In further experiments (E.S.R., 66, p. 177) n-butylidene chloride, when administered to dogs at a dose rate of 0.3 cc per kilogram of body weight, "showed an aggregate efficacy of 96.5 percent for the removal of ascarids, 100 percent for the removal of hookworms, and 7.8 percent for the removal of whipworms. n-butylidene chloride, administered to cats at a dose rate of 0.3 cc per kilogram of body weight, gave an aggregate efficacy of 90.4 percent for the removal of ascarids and 81.6 percent for the removal of hookworms. In 8 of 11 cats the drug removed all hookworms present. . . .

"Toxicity tests carried out on 2 horses indicate that n-butylidene chloride has a safety factor for the horse of at least 14 times the therapeutic dose rate of 0.2 cc per kilogram of body weight. This factor would probably be much higher where the drug is followed by an adequate dose of a suitable purgative, as is recommended for routine administration. n-butylidene chloride administered to 1 horse at a dose rate of 0.1 cc per kilogram of body weight was 100 percent effective for the removal of *Oesophagodontus robustus* and *Oxyuris equi* and showed a fair degree of efficiency against *Strongylus* spp. and cylicostomes, even though the animal in question did not receive an adequate dose of purgative. It seems probable that n-butylidene chloride could be recommended for administration at this dose rate provided the drug is followed by an adequate dose of raw linseed oil. However, additional tests are needed to establish this point.

"Clinical tests with n-butylidene chloride gave satisfactory results and stopped losses in a herd of calves dying of parasitism.

"n-butylidene chloride administered to adult chickens in doses of 1 to 6 cc gave an aggregate efficacy of 98.4 percent for the removal of *Ascaridia lineata*. The drug in doses of 2 cc or more removed all specimens of *Ascaridia* present in experimental birds. n-butylidene chloride was not generally effective for the removal of *Heterakis gallinarum*, showing an aggregate efficacy of only 4.7 percent against this species of worm."

Some observations on chlorin as a disinfectant, W. L. CHANDLER (*Jour. Amer. Vet. Med. Assoc.*, 82 (1933), No. 1, pp. 95-99).—In work conducted at the Michigan Experiment Station avian fecal matter containing oocysts was rendered bacteriologically sterile by suspending it for several hours in the ice box in a sodium hypochlorite solution containing 1 percent available chlorine.

The experimental work has shown "that when 0.1 cc of concentrated (centrifuged) finely divided fecal matter containing coccidial oocysts is shaken in a test tube with 10 cc of a hypochlorite solution containing, after acidification, not less than 0.1 percent available chlorine and hydrochloric acid in amount corresponding to in excess of N/10, coccidial oocysts are killed within 10 minutes. This same method apparently also kills all of the bacteria present in the fecal matter, as attempts to culture bacteria from the contents of test tubes after a 10-minute exposure consistently failed."

The author concludes that the action of strongly acidulated hypochlorites in killing coccidial oocysts and in sterilizing fecal matter is due to direct chlorination.

The relation of temperature to the germicidal efficiency of lye solutions, E. C. McCULLOCH (*Jour. Bact.*, 23 (1932), No. 1, pp. 50, 51).—This is a digest of work with lye as a disinfectant conducted at the Wisconsin Experiment

Station, as referred to in the station report previously noted (E.S.R., 67, p. 740). Dilute solutions of high-grade household lye were found very efficient in destroying *Brucella abortus*, *Escherichia coli*, and other related microorganisms.

"In studies in barn disinfection, no nonsporulating organisms were recovered in subculture from floors or gutters after 5 minutes' exposure to a 1:150 lye solution. A decrease in temperature was found to exert relatively small influence upon the germicidal efficiency of lye solutions. Little consistent difference in the killing time was noted in trials made at 2° and 25° C. Electrometric pH determinations of the lye solutions at various temperatures indicate that the ratio of hydroxyl-ion to hydrogen-ion activity decreases with increase in temperature."

The rôle of disinfection in the control of Bang's disease, E. C. McCULLOCH (*Vet. Med.*, 27 (1932), No. 11, pp. 458-461).—Particular attention is called to the value of a lye solution as a disinfectant, as above noted. It was found that the 1:150 dilution of lye, made by adding one 13-oz. can of high-test lye to 15 gal. of water, almost instantly destroyed *Brucella abortus* as well as all other Gram-negative, nonsporulating rods. Whitewash, if freshly made from quick lime, is a very efficient germicide against *B. abortus*, *Escherichia coli*, and related microorganisms. The addition of cresol compounds to whitewash did not increase its germicidal efficiency.

Bovine anaplasmosis: A method of obtaining pure strains of *Anaplasma marginale* and *Anaplasma centrale* by transmission through antelopes, W. O. NEITZ and P. J. DU TOIT (*Union So. Africa Dept. Agr. Rpt. Dir. Vet. Serv. and Anim. Indus.*, 18 (1932), pt. 1, pp. 3-20, figs. 9).—In this contribution the authors consider the transmission of *Anaplasma* to blesbok, duiker, and sheep. "*A. marginale* could be demonstrated microscopically in the blood of the blesbok and the duiker. These animals do not manifest clinical symptoms as a result of the infection. *A. marginale* could not be seen microscopically in sheep, but was demonstrated by subinoculation into a susceptible calf. *A. centrale* could not be seen microscopically in the blesbok, but was demonstrated by subinoculation into susceptible cattle. *P[iroplasma] bigemum* and *Th[elazia] mutans* could not be transmitted to the blesbok and the former not to the duiker. *A. marginale* and *A. centrale* were obtained in a pure state by passage through these antelopes. The morphology as well as the virulence of these parasites are not changed by passage.

"Experiments should be carried out to determine whether any other families besides the Bovidae, e. g., Cervidae and Camelidae, belonging to the group Pecora are also susceptible to anaplasmosis. There is good reason to believe that anaplasmosis can be transmitted to buck by ticks. This fact will have to be taken into consideration when measures are taken to control this disease. Furthermore, this may explain why anaplasmosis occurs on farms where it is known to be absent for years. The evidence available seems to indicate that anaplasmosis was primarily a disease of antelopes, and that bovines were infected when brought into areas where the disease occurred."

A discussion of some fundamental principles and practices underlying the application of the agglutination tests for Bang's disease, C. P. FITCH and C. R. DONHAM (*Jour. Amer. Vet. Med. Assoc.*, 82 (1933), No. 1, pp. 46-54).—This is a contribution from the Minnesota Experiment Station, the details of which are reported in tabular form.

The drawing and handling of blood samples for the serological diagnosis of Bang's abortion disease (*Connecticut Storrs Sta. Spec. Bul.*, Nov. 1931, pp. 4, fig. 1).—Directions are given for the drawing and handling of blood samples.

Effect of trypan blue, thionin, and pyronin on the agglutination titre of cows infected with Bang's disease, E. E. SLATTER and R. GRAHAM (*Jour. Amer. Vet. Med. Assoc.*, 82 (1933), No. 1, pp. 76-78).—In work in Illinois three groups of six animals each, positive to the agglutination test for Bang's disease, continued to show titers of 1:50 to 1:20 for eight months after treatment with trypan blue, thionine, or pyronine, respectively. No evidence was obtained to suggest that trypan blue, thionine, or pyronine altered the agglutinin titer of the blood or milk sera of the treated animals.

Treatment for mastitis with ultraviolet light, formalin, colloidal carbon, and autogenous bacterins, E. M. GILDOW, H. C. HANSEN, and V. A. CHERINGTON (*Jour. Amer. Vet. Med. Assoc.*, 82 (1933), No. 1, pp. 55-64, figs. 2).—In work at the Idaho Experiment Station, "no consistent reduction in the number of bacteria or leucocytes in the middle milk of cows affected with subacute or chronic mastitis was obtained following treatment with formalin, colloidal carbon, autogenous bacterins, or ultraviolet light. Four cows . . . were treated by all four methods without showing significant reductions in bacteria or leucocyte counts. Of the 10 cows treated with two or more of these methods, only 1 . . . shows a permanent recovery, as designated by a return to a normal bacteria and leucocyte count in the milk. This cow was infected with *Streptococcus subacidus*. She was treated first with ultraviolet light in September 1930, and with autogenous bacterin in March 1931. Both the bacteria and leucocyte counts were normal following the use of autogenous bacterin and have remained so on subsequent quarterly herd tests.

"No conclusive statement can be made concerning the relative effectiveness of the different treatments used insofar as correction of clinical symptoms is concerned. The limited data obtained in the treatment of these cases, however, do corroborate the findings of other investigators in that none of the treatments used was effective in eliminating the causative organism from the udder or even in regularly reducing the number of organisms or associated leucocytes."

Contribution to the diagnosis and control of paratuberculosis [trans. title], M. J. J. HOUTHUIS (*Tijdschr. Diergeneesk.*, 60 (1933), No. 1, pp. 6-16; *Ger., Eng., Fr. abs.*, pp. 14-16).—This is a report of studies of 44 bovines suffering from paratuberculosis.

Growth and metabolism of the bovine pleuro-pneumonia virus, B. E. HOLMES and A. PIRIE (*Brit. Jour. Expt. Path.*, 13 (1932), No. 4, pp. 364-370, figs. 3).—A report of studies made with a view to estimating the growth of the filter-passing organism of bovine pleuropneumonia by estimating its metabolism. There was found to be "little or no production of ammonia in cultures and no perceptible increase in amino nitrogen (formol titration). There is a very slight fermentation of glucose during the first 24 hours of culture and a very large fermentation during the second 24 hours. This increase of metabolic activity probably indicates increase in the amount of organism present. The pleuropneumonia virus can reduce methylene blue in the presence of sodium lactate. The growth of the virus in culture can thus be conveniently estimated by following the increase in lactic dehydrogenase in the culture."

Contagious bovine pleuro-pneumonia control by culture vaccines, S. C. J. BENNETT (*Jour. Compar. Path. and Ther.*, 45 (1932), No. 4, pp. 257-292).—This is a report of work conducted with the dual purpose of adapting cultures of the pleuropneumonia virus for use as vaccines in the Sudan and of ascertaining with more precision than hitherto some details of their properties and limitations. It was found that a single dose of living culture, even of many generations, will produce an immunity. Virus cultures (vaccines) stored without transplantation were found to require a longer period to produce immunity than fresh cultures.

Avian tuberculosis in cattle in Great Britain, F. C. MINETT (*Jour. Compar. Path. and Ther.*, 45 (1932), No. 4, pp. 317-330).—"The natural occurrence of avian tuberculosis in cattle in Great Britain is reported. The nature of the infection was established in three calves and in two adult bovines, belonging to three herds, but it was probable that other cases among calves existed in at least one of these herds. In two of the herds tuberculosis was proved to exist among the fowls, and these had free access to the cattle. In four instances the organisms were isolated from glands of the alimentary tract and in the fifth instance from the apparently normal intestinal mucous membrane.

"Four of the five cases were detected as a result of reactions to the intradermal Johnin test, but where tests were made the animals reacted still more strongly to avian tuberculin and in a smaller degree to mammalian tuberculin. Post-mortem examination, however, failed in all cases to show the presence of bovine tuberculosis or John's disease. With two animals strong reactions to avian tuberculin or Johnin could be elicited for a period of six months after removal from the source of infection, but at the time of slaughter one of these had apparently overcome the infection.

"The strains of avian tubercle bacilli from the calves were highly virulent for rabbits and fowls; those from two adult cattle were of low virulence, probably owing to a more prolonged residence in mammalian tissues."

Black leg in sheep due to shearing, I. E. NEWSOM and F. CROSS (*Vet. Med.*, 28 (1933), No. 1, pp. 16-20, figs. 2).—This contribution from the Colorado Experiment Station reports upon an outbreak of blackleg in sheep due to shearing wounds, 145 out of a band of 2,000 having been lost. The diagnosis was confirmed by bacteriological cultures. Some tests were made which showed the relative value of commercial aggressins and bacterins.

Vaccination against braxy with formalinised but living whole-cultures, N. DUNGAL (*Jour. Compar. Path. and Ther.*, 45 (1932), No. 4, pp. 313-316).—It is pointed out that vaccination against braxy has been practiced in Iceland since 1897. "Dried cultures prepared by the Danish Serum Laboratory and our antiserum have been most used, on the whole with good results. Since 1929 a new kind of vaccine, consisting of slightly formolized whole cultures, has been introduced by our laboratory and has given constantly better results than the Danish vaccine as shown by the vaccination reports. Although the vaccine contains a number of living spores the reactions are very slight and losses from vaccination negligible."

Contagious abortion of sheep and goats in Cyprus, F. H. MANLEY (*Jour. Compar. Path. and Ther.*, 45 (1932), No. 4, pp. 293-300, figs. 4).—A report is given of an outbreak of contagious abortion of sheep and goats in Cyprus. The causative organism is apparently closely allied to the strains of *Bacterium abortus ovis* isolated in England. The association of goats with an outbreak of this nature is reported for the first time. It was found that abortion can easily be produced in sheep and goats by artificial infection with the organism. In one small experiment two inoculations of formolized culture appeared to give complete protection against a subsequent dose of live culture, a similar dose of living culture producing abortion in a control ewe.

A liver function test in sheep, J. N. SHAW (*Jour. Amer. Vet. Med. Assoc.*, 82 (1933), No. 2, pp. 199-204, figs. 3).—In this contribution from the Oregon Experiment Station the author reports having found that the excretory function in livers of sheep infested with both immature and mature *Fasciola hepatica* was not affected, as determined by the rose bengal dye test here described, except in one instance. "Carbon tetrachloride in doses greater than necessary to kill immature and mature flukes did not produce sufficient damage to the liver to be detected by use of this test. The excretory function of the liver

of sheep suffering from so-called pregnant-ewe paralysis was markedly affected, as indicated by the rose bengal test."

"Tick-borne fever", a hitherto undescribed disease of sheep, W. S. GORDON, A. BROWNLEE, D. R. WILSON, and J. MACLEOD (*Jour. Compar. Path. and Ther.*, 45 (1932), No. 4, pp. 301-312, figs. 4).—The authors find that a hitherto undescribed disease occurs in sheep on at least some of the tick-infested farms of Scotland. "When transmitted by inoculation it is characterized by an incubation period of about 4 days, followed by a febrile phase which lasts about 10 days. The presence of the infective agent has been demonstrated in the blood, spleen, and central nervous system. The mortality incidence is low, and after recovery most animals are comparatively immune to further infection. In animals killed during the febrile phase the only pathological change observed is splenic enlargement. The infective agent is transmitted by the tick *Ixodes ricinus* L."

Pseudo-tuberculosis of sheep due to *B. pseudotuberculosis rodentium* (so-called "pyaemic hepatitis"), E. M. PULLAR (*Aust. Vet. Jour.*, 8 (1932), No. 5, pp. 181-183).—A report upon a fairly extensive and serious outbreak of so-called pyaemic hepatitis in sheep which occurred in flocks in two widely separated districts of Victoria.

The effects of sulphur on merino sheep and their resistance to potassium cyanide poisoning, D. G. STEYN (*Union So. Africa Dept. Agr., Rpt. Dir. Vet. Serv. and Anim. Indus.*, 18 (1932), pt. 2, pp. 597-610, fig. 1).—It was found that merino wethers and ewes which had received sulfur over a period of 2 years showed a much greater increase in body weight and wool yield than the control animals. The controls showed a higher degree of worm infestation than the sulfur-treated sheep. Of the sulfur-dosed wethers, 37.5 percent succumbed to the effects of urinary calculi, whereas the two control wethers continued in good health. The sulfur-treated sheep showed a fair degree of resistance to potassium cyanide.

A new disease of moose, II, G. I. WALLACE, L. J. THOMAS, and A. R. CAHN (*Soc. Expt. Biol. and Med. Proc.*, 29 (1932), No. 9, pp. 1098-1100).—This second contribution (E.S.R., 68, p. 531) reports studies of the causative organism of the new disease of moose, it having been repeatedly isolated from ticks taken from a diseased animal. It has also been isolated from guinea pigs that died after winter ticks from a diseased moose had engorged upon them. The organism grows very abundantly on all ordinary laboratory media. It is a vigorous fermentor, is capsulated, and apparently produces a toxin. The growth on agar is excessively mucoid, while in broth it grows very well throughout the medium with a great deal of sedimentation. It produces beta hemolysis on blood agar. Growth is exceedingly rapid, covering the entire surface of an agar slant within five hours. Indications are that it may be a member of the *Klebsiella* group in a rod form with a tendency to assume a coccoid shape.

A new disease of moose.—III, A new bacterium, A. R. CAHN, G. I. WALLACE, and L. J. THOMAS (*Science*, 76 (1932), No. 1974, pp. 385, 386).—In this third contribution (see above), the name *Klebsiella paralytica* is applied to the causative organism of the new disease of moose.

Studies in infectious enteritis of swine.—VII, Studies on the use of colloidal iodine in swine coccidiosis, H. E. BIESTER and C. MURRAY (*Jour. Amer. Vet. Med. Assoc.*, 82 (1933), No. 1, pp. 79-83, fig. 1).—In this further contribution on the subject (E.S.R., 68, p. 382), it is reported that colloidal iodine in large repeated doses did not in any way influence the course of controlled coccidial infections in swine. It is thought that a slight anthelmintic action against roundworms following large, repeated doses might be attributed to it.

Internal parasites of swine, M. C. HALL (*Vet. Med.*, 28 (1933), No. 1, pp. 26-33, figs. 21).—A practical, illustrated digest of the more important internal parasites of swine.

Cell proliferation response to sulphydryl on an epithelial defect in horses, C. E. HOWELL (*Jour. Amer. Vet. Med. Assoc.*, 82 (1933), No. 1, pp. 100-104, figs. 3).—"Evidence is here presented showing that sulphydryl compound thioercsol definitely stimulated mitosis in one case of summer sores in horses. This defect has been one of the most resistant conditions to healing known in horses. Favorable results have been obtained by the use of the sulphydryl group in stimulating mitosis in normal as well as persistent wounds. The successful treatment of this case of summer sores in this horse points to the fact that advantage might well be taken of the use of this substance in the treatment of persistent wounds in animals."

Bang's bacillus, *Brucella abortus*, pathogenic in the horse [trans. title], L. PANISSET and P. DELBÉ (*Rev. Gén. Méd. Vét.*, 41 (1932), No. 491, pp. 670-675).—A brief discussion of the occurrence of *B. abortus* in the horse, presented with a list of 12 references to the literature.

Infections of fetuses and foals, W. W. DIMOCK and P. R. EDWARDS (*Kentucky Sta. Bul.* 333 (1932), pp. 287-339, figs. 3).—In the studies conducted (E.S.R., 68, p. 527) streptococci were found in aborted fetuses more frequently than any other micro-organism. *Shigella equirulis*, *Escherichia coli*, and staphylococci were discovered occasionally in aborted fetuses but were of minor importance. Many instances of apparently noninfectious abortion were observed, these having occurred both sporadically and as well-defined outbreaks, the cause of the majority of which is undetermined.

"*S. equirulis* was found responsible for the death of a larger number of foals than any other micro-organism. Streptococci, also, were responsible for the death of many foals. *E. coli* and *Corynebacterium equi* were found occasionally in diseases of foals. In many instances diseases of foals were prenatal in origin. *S. equirulis* was rarely found in the genital tract of the dam of a foal that had died of this infection. This bacterium has no tendency to become localized permanently in the genital tract. *S. equirulis* was present almost constantly in the mouth and pharynx of the normal horse. Streptococci invade the uterus of the mare shortly following parturition. Sometimes they become established and produce genital infection. Through careful observation of mares that have fouled it is possible to determine whether a normal recovery is being made, and by proper care and treatment to prevent many cases of genital infection."

Spontaneous and experimental *Brucella* infection in the dog [trans. title], J. VAN DER HOEDEN (*Tijdschr. Diergeneesk.*, 59 (1932), No. 24, pp. 1446-1460; *Ger., Eng., Fr. abs.*, pp. 1455-1457).—The author examined the blood sera of 442 dogs and found that in several cases agglutinins (16.3 percent) and complement-fixing antibodies (10.2 percent) against *Brucella* were present. It appears that dogs living in a room with infected dogs may also become infected. It is pointed out that the dog must be considered as a possible source of infection in the epidemiology of brucellosis in man and animals.

Studies on canine distemper.—III, A comparison of natural and experimental virus infections, A. S. SCHLINGMAN (*Jour. Amer. Vet. Med. Assoc.*, 82 (1933), No. 2, pp. 164-189, figs. 14).—This is in continuation of the contribution previously noted (E.S.R., 68, p. 533), presented in connection with a list of 14 references to the literature.

"A comparison of the symptoms seen occurring after natural infection with those produced in dogs by the injection of the filtrable virus indicate that these two diseases, both of which are called canine distemper, are separate

and distinct. This conclusion is substantiated further by the fact that the dogs which had recovered from natural infection, the majority of which cases have been found to be due to *Bacillus bronchisepticus*, were not immune to the virus of experimental dog distemper, and, vice versa, dogs recovered from infection with this virus were not immune to natural infection. . . .

"Ferrets recovered from fitch distemper possessed a solid immunity against infection with the virus of experimental dog distemper, but dogs recovered from fitch distemper developed either an immunity of low grade or of short duration to infection with this virus. . . . Dogs recovered from fitch distemper were not immune to infection by contact with naturally infected cases.

"From the limited number of animals used in these experiments it would seem that while fitch distemper, ferret distemper, and infection with the virus of experimental dog distemper in the dog are similar, if not identical, these conditions are entirely different from the disease in dogs as it occurs following contact with naturally infected cases, the majority of which have been found to be caused by *B. bronchisepticus*."

An encephalomyelitis in the chicken, E. E. JONES (*Science*, 76 (1932), No. 1971, pp. 331, 332).—This is a preliminary report upon a nervous disorder of chickens first observed by the author in May 1930, at which time a group of 9 affected chickens was brought to the laboratory of the department of comparative pathology of the Medical School of Harvard University. A second group of affected birds was received in April 1931, a third in January 1932, and a fourth in May 1932.

The affection is characterized by a pronounced and rapid tremor of the head and neck, with which, in some cases, there is also an associated ataxia. The age of onset of the disease is reported to be as early as 2 days after the chickens have been removed from the incubator. The oldest affected birds under observation were from 6 to 7 weeks of age. A total of 102 affected birds was studied, detailed pathological examinations of 50 of which have been completed. Transmission experiments, in which a suspension in salt solution of brain or of spinal cord of an affected bird was inoculated intracranially into very young normal chickens, gave positive results in six cases. All efforts to produce the disease by diet, high temperature, etc., have been unsuccessful.

An account of ataxia in chicks associated with nephritis, by Dunlap, contributed from the Massachusetts Experiment Station, has been noted (E.S.R., 67, p. 748).

Immunisation of the fowl and the pigeon against epithelioma contagiosum, R. E. GLOVER (*Cambridge Univ., Inst. Anim. Path. Rpt. Dir.*, 2 (1931), pp. 1-20, pls. 2).—It is concluded that "the use of emulsions containing living virus cannot be recommended for the purpose of vaccination against fowl pox. Two inoculations of virus emulsions rendered inert by heat, formalin, or chloroform are capable of inducing a fleeting immunity. A more satisfactory protection is produced by phenol-treated emulsions. The vaccine of De Bleeck and Van Heelsbergen [E.S.R., 53, p. 785] is indistinguishable from pigeon virus. Both are of value in the production of an active immunity and are without danger when applied under suitable conditions. It is impossible to demonstrate antibodies in the sera of recovered or hyperimmunized birds."

Immunisation of fowls against fowl pox by use of pigeon pox virus, A. S. CANHAM (*Union So. Africa Dept. Agr., Rpt. Dir. Vet. Serv. and Anim. Indus.*, 18 (1932), pt. 1, pp. 111-140, figs. 3).—In experimental work pigeon pox vaccine produced a good immunity against natural cases of fowl pox but not so good an immunity against artificial infections with fowl pox virus. It was found that young birds a week old can be vaccinated with pigeon pox vaccine

with safety, and in no birds inoculated were any constitutional symptoms observed.

The relation of age, breed, and species to susceptibility to transmissible leucosis of chickens, E. L. STUEBS (*Jour. Amer. Vet. Med. Assoc.*, 82 (1933), No. 2, pp. 232-242).—The author finds that transmissible leucosis of chickens can be transmitted readily to various breeds of the fowl, and that it can be transmitted to chickens of various ages, young fowls being more susceptible. It is concluded that it cannot be transmitted from chickens to birds of other species.

Observations on a severe outbreak of mycosis in chicks, E. L. JUNGHERR (*Jour. Agr. Res. [U.S.]*, 46 (1933), No. 2, pp. 169-178, figs. 5).—Contributing from the Connecticut Storrs Experiment Station, the author reports studies made of mycosis in chicks, a disease that appeared during the summer of 1931 in a Connecticut hatchery and resulted in a loss of approximately 10,000 chicks of the 50,000 hatched during the season. It is thought to be the first report of a severe outbreak of the disease of major epidemiological importance. The chicks that survived made good recovery, and 60 days after hatching had developed into normal birds. The losses were smaller when brooding was carried out in small lots or batteries; change in feed and rigid sanitary precautions were not very effective as control measures.

"The diseased condition was characterized by whitish ulcers or pseudomembranes in the crop, brownish or mucoid deposits in the proventriculus, and ulcers in the gizzard. The lesions in small chicks were often so small as to be easily overlooked. On mycological examination yeastlike fungi were isolated from the crop, proventriculus, gizzard, gall bladder, and intestine. The predominating organism was a yeastlike fungus resembling *Monilia albicans*; the other observed types resembled *Oid um lactis* and *M. krusei*. The diseased condition was reproduced by feeding fecal material from diseased chicks and by injecting fungus cultures of the *M. albicans* type. In two instances artificially infected chicks succumbed with the *O. lactis* type. Infection experiments conducted on small lots of chicks were not uniformly successful, a point readily understood when field observations of small-lot brooding are considered. The average period of incubation under experimental conditions was 31 days, a period that closely coincided with the second mortality peak under field conditions. The second mortality peak may, therefore, have been due to postnatal infection.

"The disease may appear in septicemic form, as was indicated by the isolation of virulent fungi from the liver and gall bladder; however, the extreme virulence of the infection in very young chicks, together with the slight pathological changes that occurred and the occasional presence of focal necrosis in the liver, suggests a toxemic action of the fungi.

"Day-old chicks from the hatchery developed the disease after they had been removed from the original premises. Chicks raised on wire floors in a new, isolated colony house suffered 41.9 percent losses. The first and highest mortality peak occurred about the tenth day after hatching; the average incubation period under experimental conditions was 31 days. The cloaca of laying hens affected with a moist type of vent gleet was shown to carry yeastlike fungi. When eggs from the plant were hatched in a sterilized incubator and the chicks reared in sterilized battery brooders, the disease appeared in only a few instances. These data furnish circumstantial evidence that the disease can be transmitted through the agency of the egg, presumably on the egg.

"The fact that the owner found that brooding in batteries was safer than in colony houses, and the writer's observation that only relatively small numbers of chicks succumbed to experimental infection, suggest that management may play a part in the postnatal spread of the disease."

A specific infectious disease of chickens due to a hemolytic streptococcus, C. B. HUDSON (*Jour. Amer. Vet. Med. Assoc.*, 82 (1933), No. 2, pp. 218-231).—In this contribution from the New Jersey Experiment Stations, the author records the finding of a specific infectious disease of chickens caused by a hemolytic streptococcus. "The causative organism occurs abundantly in the blood and organs in chains of 2 to 20 cells, with chains of 6 to 8 elements predominating. The portal of entry is shown to be by way of the nasal cavity and not by way of the alimentary tract. It is demonstrated that some birds resist intranasal inoculation but become carriers of the infection, and that the organism may be isolated from the nasal cavity of such individuals. Localization of the infection following intranasal inoculation is shown in the case of two birds. The disease probably becomes established in a flock through the introduction of carrier birds or by the introduction of susceptible birds into a flock in which carriers exist."

A note on *Aegyptianella pullorum* in the fowl in South Africa, E. M. ROBINSON and J. D. W. A. COLES (*Union So. Africa Dept. Agr., Rpt. Dir. Vet. Serv. and Anim. Indus.*, 18 (1932), pt. 1, pp. 31-34, figs. 4).—The authors record the presence of what is thought to be *A. pullorum* in South Africa, the vector of which is unknown but is quite probably the fowl tick. The disease is not of much importance, especially in up-to-date plants where sanitary measures are applied. It is considered possible that the organism may prove to be the cause of a chronic fatal form of anemia which is not uncommonly seen, and for which so far no etiological factor has been discovered.

Pullorum disease: A study of the relationship of repeated agglutination tests to the bacteriology and pathology of the disease, F. D. McKENNEY (*Jour. Amer. Vet. Med. Assoc.*, 82 (1933), No. 1, pp. 65-75).—The author's studies have led to the conclusion that "the agglutination test is probably more accurate in detecting infections of pullorum disease than any method that depends on isolation of the organism from infected birds. Lesions in the ovary do not mean that a hen is necessarily affected with or is a carrier of pullorum disease; the lesions may have been produced by means other than *Salmonella pullorum*. A reaction to the agglutination test for pullorum disease is evidence of an existing infection with *S. pullorum*, and is not necessarily an immunologic reaction. Birds may recover from the disease and show no evidence of immunity by agglutinins in the blood serum. In a high percentage of fowls that have been fed the organism, infection in the ovary becomes localized."

The whole-blood, stained-antigen agglutination test for pullorum disease, E. H. BARGER and J. P. TORREY (*Jour. Amer. Vet. Med. Assoc.*, 82 (1933), No. 1, pp. 84-92, figs. 12).—It is pointed out that "the efficiency of the stained-antigen, whole-blood agglutination test for the diagnosis of pullorum disease is dependent upon many factors. A thorough understanding of the essential technic is fundamental. The antigen must be titrated accurately and mixed with the proper amount of fresh blood. The surroundings under which the tests are made also influence the accuracy of the results. Ample light is necessary in reading the results. Artificial light must be provided on cloudy days and at all times in dark poultry houses. For this purpose, electric light from batteries or a common flashlight may be employed. Partial, flaky, or pseudoreactions must not be confused with true agglutination."

Incubator hygiene in the control of pullorum disease, R. GRAHAM and V. M. MICHAEL (*Illinois Sta. Circ.* 403 (1933), pp. 16, figs. 7).—A practical account, in which it is pointed out that formaldehyde fumigation of forced-draft incubators by either the cheesecloth method or the potassium permanganate method is of definite value in suppression of pullorum disease, but is not a substitute for disease-free flocks.

The hydrogen-ion concentration of fowl's blood in Rous' sarcoma and in infections (avian tuberculosis and salmonellosis), M. J. A. DES LIGNERIS, M. D. BERNE, and L. M. S. S. A. LOND (*Brit. Jour. Expt. Path.*, 13 (1932), No. 3, pp. 189-200).—It was found that in fowls infected with Rous' sarcoma the pH of the blood rises and remains high until just before death. It also rose in fowls infected with avian tuberculosis and *Bacterium gallinarum* and fell again in the later stages of the disease.

Types of leg disorders affecting growing chicks, R. M. BETHKE (*Jour. Amer. Vet. Med. Assoc.*, 82 (1933), No. 3, pp. 476-479).—Contributing from the Ohio Experiment Station the author describes four different leg disorders affecting growing chicks, namely, rickets, or true leg weakness; slipped tendon, hock disease, or perosis; crazy chicks; and nutritional paralysis. Each is discussed separately with respect to cause, occurrence, symptoms, and prevention so far as known.

Leg disorders of growing chicks, R. M. BETHKE and P. R. RECORD (*Ohio Sta. Bimo. Bul.*, 18 (1933), No. 2, pp. 48-50, figs. 2).—Rickets, hock disease, crazy chicks, nutritional paralysis, and range or fowl paralysis are the conditions discussed.

Tuberculosis of avian origin in muscovy ducks, W. R. HINSHAW (*Jour. Amer. Vet. Med. Assoc.*, 82 (1933), No. 1, pp. 111-113, fig. 1).—Contributing from the California Experiment Station, the author reports upon two cases of tuberculosis in muscovy ducks originating from the same ranch in central California. Animal inoculations with infective material from one of the ducks and the fact that the flock was associated with a tuberculous flock of chickens indicated that they were suffering from the avian type of the disease.

An outbreak of fowl-typhoid in guinea fowls (*Numida meleagris*), E. P. JOHNSON and G. W. ANDERSON (*Jour. Amer. Vet. Med. Assoc.*, 82 (1933), No. 2, pp. 258, 259).—In a study in Virginia of a disease occurring in a flock of some 100 guinea fowls, in which 1 or 2 had been dying daily without any symptoms noticeable to the owner, the authors isolated an organism which they conclude is identical with that of fowl typhoid. The outbreak is said to have continued until about 30 percent of the birds had died. It was checked by prompt removal of the sick birds and by thorough cleaning and disinfection of the premises.

Staphylococcal arthritis in turkeys, E. JUNGHERR (*Jour. Amer. Vet. Med. Assoc.*, 82 (1933), No. 2, pp. 243-249, figs. 4).—This contribution from the Connecticut Storrs Experiment Station reports upon an infectious disease of turkeys characterized by polyarthritic symptoms, and a more or less systemic reaction is known to occur in geese and ducks and sometimes chickens and pheasants. It is caused by *Staphylococcus aureus*, and occasionally by *S. citreus*, having been described in the literature as staphylococcosis, staphylococcosis, lameness of geese and ducks, osteo-arthritis, etc.

The author has found that the disease may occur as an acute septicemia and in a chronic arthritic form. Only the arthritic form has been observed in turkeys, although the acute septicemic form may occur and should be watched for.

AGRICULTURAL ENGINEERING

[**Agricultural engineering investigations at the California Station**] (*California Sta. Rpt. 1932, pp. 21-27, figs. 5*).—The progress results of investigations on brooder ventilation and poultry house roofs; asphaltic concrete surfacing for barns and corrals; farm machinery, including cotton harvesters, crusher mowers for hay, hay choppers, and cross blockers for beets; machinery and fire for controlling weeds and insects; fire prevention; soil heaters; and orchard heaters are briefly reported.

[**Agricultural engineering investigations at the Indiana Station**] (*Indiana Sta. Rpt. 1932, pp. 14-17, fig. 1*).—The progress results are briefly presented of investigations on the combined harvester-thresher, soil erosion prevention by Mangum terraces, management of air-cooled apple storage, temperature and humidity in poultry houses, the field silage harvester, the hay and grain drier, mechanical corn production, low corn cutting, clean plowing accessories, mechanical corn picker losses, electric soil heating, electric dairy water heaters, power consumption of stationary and portable methods of spraying, and the value of grinding grains for dairy calves.

[**Agricultural engineering investigations at the Iowa Station**], J. B. DAVIDSON ET AL. (*Iowa Sta. Rpt. 1932, pp. 15-18, figs. 2*).—The progress results are briefly presented of investigations of corn production methods, including the use of corn picker-harvesters; the all-masonry barn, the use of tractors, and tractor track efficiency.

[**Agricultural engineering investigations at the New York Cornell Station**], F. L. FAIRBANKS, A. M. GOODMAN, J. C. HUTTAR, H. E. BOTSFORD, and H. W. RILEY (*New York Cornell Sta. Rpt. 1932, pp. 89, 90*).—The progress results of investigations of the ventilation of poultry houses for laying and breeding hens, and of milk-cooling equipment are briefly reported.

[**Agricultural engineering investigations at the Ohio Station**], R. C. MILLER, N. R. BEAR, C. O. REED, R. M. SALTER, V. L. OVERHOLT, E. A. SILVER, G. W. MCCUEN, M. A. BACHTELL, W. E. WEAVER, J. S. CUTLER, and H. S. ELLIOTT (*Ohio Sta. Bul. 516 (1933), pp. 101-106, 108, 110, 111, fig. 1*).—The progress results of investigations on corn storage, effect of seed-bed preparation on corn yield, corn planters, drainage, feed mills, threshing machines, hay chopping, soil chisel and mole drainage, and methods of handling hay are briefly reported.

Surface water supply of the United States, 1931, Parts 1, 2, 5, 12 B (*U.S. Geol. Survey, Water-Supply Papers 711 (1933), pp. IX+310, fig. 1; 712 (1933), pp. VII+233, fig. 1; 715 (1933), pp. VI+172, fig. 1; 723 (1933), pp. VII+205, fig. 1*).—Of the papers which here present the results of measurements of flow made on streams during the year ended September 30, 1931, No. 711, prepared in cooperation with the States of Connecticut, Maine, Maryland, Massachusetts, New Hampshire, New Jersey, New York, Pennsylvania, Vermont, Virginia, and West Virginia, covers the North Atlantic slope drainage basins; No. 712, prepared in cooperation with the States of Alabama, Florida, Mississippi, North Carolina, South Carolina, and Virginia, the South Atlantic slope and eastern Gulf of Mexico basins; No. 715, prepared in cooperation with the States of Illinois, Indiana, Minnesota, Missouri, North Dakota, and Wisconsin, the Hudson Bay and upper Mississippi River Basins; and No. 723, prepared in cooperation with the States of Idaho, Nevada, Oregon, and Washington, the Snake River Basin.

Surface water supply of Hawaii, July 1, 1929, to June 30, 1930 (*U.S. Geol. Survey, Water-Supply Paper 710 (1933), pp. V+101*).—This report,

prepared in cooperation with the Territory of Hawaii, presents the measurements of flow made on streams and ditches in the Territory during the year ended June 30, 1930.

Chemical character of surface waters of Virginia, W. D. COLLINS, E. W. LOHR, K. T. WILLIAMS, H. S. HALLER, and O. C. KENWORTHY (*Va. State Comm. Conserv. and Devlpmt., Div. Water Resources and Power Bul. 3 (1932), pp. [7]+148, pl. 1, figs. 7*).—This report, which was prepared in cooperation with the U.S. Geological Survey, presents data on the chemical composition of rivers and streams in Virginia. The main constituents of the water are calcium, magnesium, and bicarbonate. The general softness of the waters of the Coastal Plain and of the Piedmont is evident.

Interpretation of laboratory findings in rural spring water supplies, E. K. KLINE and N. M. FULLER (*Amer. Jour. Pub. Health, 22 (1932), No. 7, pp. 691-699, figs. 5*).—In a contribution from the Cattaraugus County (N.Y.) Department of Health, results of a study of the influence of salamanders on rural water supplies are reported.

It was found that salamanders live in large numbers deep within the shale along the underground streams. At certain seasons they come to the surface and travel a distance of at least 65 ft. overland where they feed on insects, worms, fly larvae, and similar food. Should these be infected with *B. coli* through improper protection of the area from direct fecal pollution or surface drainage the salamanders become infected. They then return to the depths and throw off *B. coli* for a considerable time. Laboratory tests on such a water supply would suggest condemnation even though the supply was otherwise unpolluted.

Preparation of potable water with "Carbosteril" [trans. title], M. JAENICKE (*Gesundh. Ingen., 55 (1932), No. 49, pp. 585-587, figs. 2*).—The results are briefly reported of tests of a method of preparing potable water in small quantities from ponds, streams, and swamps which involved chlorination, treatment with pulverized activated carbon, and removal of the carbon by filtration. It was possible by this means to produce water from such sources which was satisfactory physically, chemically, and bacteriologically. It was found that the adsorptive action of the activated carbon reduced the bacterial content of water appreciably, but that in order to insure absolute safety in this respect chlorination is necessary.

Stream pollution by irrigation residues, C. S. SCOFIELD (*Indus. and Engin. Chem., 24 (1932), No. 11, pp. 1223, 1224*).—In a contribution from the U.S.D.A. Bureau of Plant Industry, briefly summarized observations from the Rio Grande Valley irrigation area in Texas, the Yuma Valley irrigation area in Arizona, and the Imperial Valley irrigation area in California indicate that the normal operation of an irrigation project results in diminishing the volume of discharge of water without a corresponding decrease in the quantity of dissolved salts. In other words, the diversion of water from a stream for irrigation use operates normally to increase the concentration of salts in the stream water. From this it becomes apparent that in formulating a program for the most complete and effective utilization of the streams of desert regions, consideration should be given to the ultimate disposition of the salt burden.

It follows that the effective drainage of irrigated land, so designed and operated as to remove the residual soluble salts, is essential to the continued safe use of any water supply for irrigation. The character and quantity of the returned drainage water must be taken into account in any plans for the utilization of water from the lower part of a river in arid or semiarid regions.

Drainage of land overlying an artesian ground-water reservoir, O. W. ISRAELSEN and W. W. McLAUGHLIN (*Utah Sta. Bul.* 242 (1932), pp. 56, figs. 16).—The publication is based on data gathered under a cooperative agreement between the station and the U.S.D.A. Bureau of Agricultural Engineering. It reports investigations on the Cache Valley artesian basin area in Utah, during which a total of 773 static water-level measurements were made at more than 50 points throughout the area. Two large wells were used to facilitate pumping from the water-bearing gravels, and 25 flowing wells ranging from 2 to 5 in. in diameter were also used.

Field measurements of the direction of flow of water in soils show that water flows upward through the compact soils overlying the artesian ground-water reservoir. The piezometric surface was appreciably lowered by the flowing of water from the artesian wells. Pumping caused a marked lowering of the piezometric surface at a distance of 1,500 ft. from the pump, an appreciable lowering at a distance of 3,000 ft., and no lowering at a distance of 10,000 ft. It is physically feasible to pump water out of the gravel in large enough streams (and also large enough in total volume) to prevent the flow of water upward, and further to permit the flow of excess irrigation water and natural precipitation downward through the upper feet of soil as fast as the low permeability of the soil will let it flow. Measurement of discharge of water from tile drains in lands east of the artesian area did not show any relationship to the pumping of water from the artesian ground water reservoir.

An appendix gives detailed data.

Mole drainage, J. H. BLACKBAY (*Univ. Oxford, Inst. Res. Agr. Engin., Tech. Notes Mech. Farming*, No. 1 (1932), pp. 21, pls. 5).—This pamphlet brings together such information as is available on mole drainage. A bibliography is included.

Investigation on water movement in permeable earth bodies [trans. title], O. JAHN (*Wasserkr. u. Wasserwirtsch.*, 27 (1932), No. 16, pp. 181–186, figs. 9).—This is a mechanical analysis of the movement of water through earth dams, the purpose of which is to provide a theory for the use of designing engineers.

The structure of clay and its importance in foundation engineering, A. CASAGRANDE (*Jour. Boston Soc. Civ. Engin.*, 19 (1932), No. 4, pp. 168–221, figs. 31).—This is a contribution from the U.S.D.A. Bureau of Public Roads, in which an attempt is made to illustrate the fact that in the building of foundations on clay it is important that the natural structure of the clay be not disturbed, since a definite bearing value of clay does not exist.

Soil action under load shown by test, D. P. KRYNINE (*Engin. News-Rec.*, 109 (1932), No. 26, pp. 782–784, figs. 3).—The results of studies at Yale University are briefly reported in which the movement of soil under a test load was disclosed by excavating a vertical cut under the loaded area and by observing the soil movement and moisture condition.

The influence of systems of cropping and methods of culture on surface runoff and soil erosion, M. F. MILLER and H. H. KRUSEKOPF (*Missouri Sta. Res. Bul.* 177 (1932), pp. 32, figs. 9).—An investigation covering a 14-year period is described, the object of which was to determine the influence of different systems of cropping and cultural treatment on surface run-off and soil erosion. The soil on which the investigation was carried out was a rather poor quality of Shelby loam having an average grade of 3.68 percent. The plats were 6 ft. wide and 90.75 ft. long, extending lengthwise up and down the slope and ending in concrete catchment basins to receive the run-off water and eroded soil. There were originally seven of these with different cropping and cultural systems, but only six were carried without change for the 14-year period.

The average yearly precipitation for the 14-year period was 40.37 in. as compared with a 44-year average of the local Weather Bureau of 37.80 in. The average monthly precipitation during the period was somewhat above the 44-year normal for all months excepting January, February, July, and December.

During the 14-year period the run-off varied from 12 percent of the rainfall for the bluegrass sod to 30.7 percent for the land plowed 4 in. deep and kept in cultivated fallow. That from the continuous corn was 29.4, from the continuous wheat 23.3, and from the rotation 13.8 percent. The run-off from a 4-in. plowing was only 0.4 percent above that from an 8-in. plowing.

The average annual erosion per acre varied from 41 tons for the land plowed 4 in. deep and left in cultivated fallow to only 0.34 ton for the continuous bluegrass sod. The annual erosion from continuous corn was 19.74 tons per acre, that from continuous wheat 10.10 tons, and that from the rotation only 2.78 tons.

The 8-in. plowing lost annually only 0.56 ton per acre less soil than the 4-in. plowing. For the conditions of this investigation, therefore, the results fail to substantiate the common belief that deep plowing is markedly better than shallow plowing in erosion control.

During the six months of the corn production season, April to September, the erosion loss from continuous corn averaged 4.7 times that from corn grown in the rotation of corn, wheat, and clover. Similarly the run-off from the continuous corn was 2.5 times that from the rotated corn.

The number of units of run-off water necessary to remove one unit of soil varied from 34 for cultivated fallow to 1,666 for continuous sod. In general the units of run-off necessary to remove a unit of soil from the cultivated land was much less than from the cropped land.

A 4-year experiment with soybeans in rows 3.5 ft. apart, running with the slope, and an experiment of similar length with soybeans drilled 8 in. apart (all beans followed by a rye cover), showed that the run-off from the beans in rows was 84 and that from the drilled beans 74 percent of the run-off from continuous corn during the same years. Similarly the erosion from the beans in rows was 94 and from the drilled beans 43 percent of that from continuous corn.

The annual losses of plant nutrients in the eroded soil from continuous corn or wheat, as determined during a 2-year period, were shown to be as great as or greater than those through the crop grown. Under a good cropping system or grass these erosion losses were in most cases reduced to amounts much less than those through crops.

Mechanical analyses of the eroded material from the different plats showed that the uncropped plats and the one in corn lost more sand than the others, due evidently to the greater velocity of the run-off water on the bare soil surface.

American tentative standard symbols for heat and thermodynamics (*New York: Amer. Standards Assoc., Sect. Com. Sci. and Engin. Symb. and Abbrev., 1931, pp. 7*).—This set of standard symbols was prepared by the Sectional Committee on Scientific and Engineering Symbols and Abbreviations and approved by the American Standards Association.

Graphic statics, S. FAIRMAN and C. S. CUTSHALL (*New York and London: McGraw-Hill Book Co., 1932, pp. VIII+145, figs. 136*).—The fundamental principles of graphic statics are elucidated in this book and their relation shown to trusses and hents, cranes, derricks, dredges, and other machines. An appendix presents the graphical solution for certain special problems, including centroid and moment of inertia of an area and bending moments in different planes.

Stresses in simple structures, L. C. URQUHART and C. E. O'ROURKE (*New York and London: McGraw-Hill Book Co, 1932, 2. ed., pp. 1X+339, figs. 260*).—This is the second revised edition of this book. It contains chapters on definitions and principles, fundamental principles of graphic statics, roof trusses; stresses in framed bents, bridge trusses under dead load, stresses in trusses due to uniform live loads, concentrated moving loads on beams and girders, concentrated moving loads on trusses, lateral forces on bridge trusses, influence lines, three-hinged arches, and deflection.

Continuous frames of reinforced concrete, H. CROSS and N. D. MORGAN (*New York: John Wiley & Sons; London: Chapman & Hall, 1932, pp. X+343, pl. 1, figs. 299*).—This book picturizes deformations in structural frames and emphasizes the importance of this process and the elementary nature of the geometry involved. It contains chapters on statics of deflected structures; geometry of deflected structures; moment distribution; haunched beams; continuous girders—maximum moments, shears, and reactions; rigid frames; influence lines; and right arches of reinforced concrete.

When to lay wood floors over concrete subfloors, M. E. DUNLAP (*Engin. and Contract.*, 71 (1932), No. 12, pp. 275, 276, figs. 3).—Methods and apparatus developed by the U.S.D.A. Forest Service for determining the proper moisture conditions which will permit the laying of wood floors over concrete subfloors are briefly described and illustrated.

The transportation of wood in chutes, A. M. KOBOLFF and R. C. BRYANT (*Yale Univ. School Forestry Bul. 34 (1932), pp. XII+139, pl. 1, figs. 76*).—This report is in three parts. Part 1 deals with the form, construction, and operation of chutes, and part 2 presents theoretical considerations in gravity chute construction and operation. Part 3 contains a bibliography and presents coefficients of friction and angles of repose for chutes.

Production of insulating board from cornstalks, C. E. HARTFORD (*Indus. and Engin. Chem.*, 22 (1930) No. 12, pp. 1280-1284, figs. 5).—The manufacture of insulating board from cornstalks on a commercial scale is described and illustrated. Heat conductance tests made by the flat plate method gave heat conductivity coefficients varying from 0.32 to 0.345. Data also are briefly reported from tests of moisture absorption and tensile and cross-breaking strengths.

An experimental investigation of the friction of screw threads, C. W. HAM and D. G. RYAN (*Ill. Univ., Engin. Expt. Sta. Bul. 247 (1932), pp. 62, figs. 26*).—The results of an investigation are reported the purpose of which was to determine values for coefficients of friction applicable to the present-day operation of power screws. The conclusions are in considerable detail and are useful in connection with the design of power equipment for shop purposes. An appendix deals with the friction of collar thrust bearings.

The application of electric light to agriculture, F. E. ROWLAND (*Illum. Engin.*, 25 (1932), May, pp. 115-123, figs. 15).—This is a summary of information relating to electric lighting for the general farm and for the poultry farm, with special reference to conditions in England. Attention is drawn to experimental results obtained from various sources relating to the favorable influence of artificial illumination on egg production during the winter months.

The conclusion is drawn that the lighting load is comparatively so small that without the development of other uses of electricity, such as electric power and heating, rural electrification on an extensive scale would be impracticable.

Electric service for the Iowa farm.—Report No. 7, Operating cost of the individual farm electric plant, F. D. PAINE and F. J. ZINK (*Iowa State Col. Off. Pub.*, 31 (1932), No. 1, pp. 15, fig. 1).—This is a continuation of the progress

report on the rural electrification project in Iowa (E.S.R., 61, p. 478). Data obtained on the cost of operation of individual farm electric plants are analyzed and discussed.

It was found that at present-day prices of individual electric plants and fuel, electricity can be generated by such plants at a cost of approximately 50 c. per kilowatt-hour when the amount generated is about 240 kw.-hr. per year. The cost of electricity from such a plant decreases as the amount generated per unit of time increases and varies from \$1 when 100 kw.-hr. are generated to less than 30 c. when 1,000 kw.-hr. are generated per year.

It was found that the monthly use of electricity is greatest in December and least in June, varying from an average of 12.5 to 29.6 kw.-hr. per month with the storage battery plants.

Rural electrification in Oklahoma: A study of consumption and costs, E. R. MILLER (*Oklahoma Sta. Bul.* 207 (1932), pp. 135, figs. 47).—The results of a consumption and cost study conducted by the station in cooperation with the Oklahoma Committee on the Relation of Electricity to Agriculture and the Oklahoma Utilities Association are reported. For this study 22 typical electrified farms located in various parts of the State but within a radius of 125 miles from Stillwater were selected. These consisted of dairy, poultry, and general farms.

Detailed data are given relating to the use of electricity on these farms for lighting, pumping water, cooking, household and dairy refrigeration, heating water, laundering, operating dairy equipment, incubation and brooding, feed grinding, and silage cutting.

Spectroscopic studies of engine combustion, L. WITHROW and G. M. RASSWEILER (*Indus. and Engin. Chem.*, 23 (1931), No. 7, pp. 769-776, figs. 5).—This paper describes a preliminary spectrographic study of the physical and chemical processes which take place in a gasoline engine.

Separate spectrographic studies made of the flame fronts and afterglows of explosions produced with several fuels in a gasoline engine, and covering the spectral range 3,500 to 6,500 Å indicated that the reactions accompanying the afterglows are different from those taking place in the flame fronts. The visible afterglow spectrum is emitted by the same molecules which give off light during a reaction between carbon monoxide and oxygen, while visible light from the flame fronts of hydrocarbon fuels in nonknocking explosions comes largely from CH and C₂ molecules. The gasoline flame fronts in the detonating zone during knocking explosions show CH and C₂ bands only faintly, but flame fronts outside of the detonating zone exhibit both sets of bands with intensities comparable with nonknocking explosions. Addition of lead tetraethyl to the gasoline removes the knock and reestablishes the CH and C₂ bands in the light from the detonating zone. Lead is present in the flame fronts as atomic lead and molecular lead monoxide.

Progress toward a uniform method of measuring detonation, T. A. BOYD (*Indus. and Engin. Chem.*, 22 (1930), No. 12, pp. 1301, 1302).—This is a synopsis of a report of the subcommittee on methods of measuring detonation of the American Petroleum Institute Cooperative Fuel Research Steering Committee.

Laboratory experiments on gum-bearing gasolines, S. P. MARLEY and W. A. GRUSE (*Indus. and Engin. Chem.*, 24 (1932), No. 11, pp. 1298-1302, figs. 4).—In a contribution from the Mellon Institute of Industrial Research, data are presented from preliminary experiments in connection with a study of the significance of gum content of gasoline as related to gum deposits. While the results were obtained with experimental equipment under laboratory conditions, they emphasize what appears to the authors to be a new importance for one of the principles of engine design.

It was found that a moderate gum content can be tolerated in an engine if the temperature of the mixture in the manifold is kept low, but as soon as much heat is applied a fuel containing an appreciable amount of gum will begin to deposit this gum, and such deposits are heavier from a rich mixture than from a lean one. The carbon deposits in the combustion chamber are somewhat but not much greater with gum-bearing fuels at low intake temperatures, but the well-known tendency to lower carbon deposits with higher head temperatures could readily be invoked to remedy this difficulty.

The results suggest that by lowering intake manifold temperatures volatile gasolines of moderate gum content might perhaps be used without serious trouble from gum deposits. Such a possibility should be considered in its relation to the application of high antiknock cracked gasolines.

Freezing and flow points for glycerol, prestone, denatured alcohol, and methanol. J. C. OLSEN, A. S. BRUNJES, and J. W. OLSEN (*Indus. and Engin. Chem.*, 22 (1930), No. 12, pp. 1315-1317, figs. 5).—In a contribution from the Polytechnic Institute of Brooklyn, N.Y., data are presented on these antifreeze compounds.

It was found that the flow point is only a few degrees lower than the freezing point for temperatures down to -25° C. for all the materials except glycerol. Below -25° the difference tends to increase to about 7° . Commercial ethylene glycol in solutions of from 10 to 60 percent by weight and 9.1 to 57.48 percent by volume showed freezing points varying from 26.1° to -50.8° F. and flow points varying from 24.3° to 63.4° F. Synthetic methanol in solutions of from 10 to 40 percent by weight and 12.24 to 45.56 percent by volume showed freezing points varying from 19.8° to -43.6° F. and flow points varying from 16.7° to -57.1° F. Denatured alcohol in solutions of from 10 to 60 percent by weight and 11.9 to 64.66 percent by volume showed freezing points varying from 24.26° to -43.6° F. and flow points varying from 21.2° to -52.5° F.

Glycerol appears to be a considerably less efficient antifreeze than the other three materials.

Farm tractors. A. A. STONE (*New York: John Wiley & Sons; London: Chapman & Hall*, 1932, pp. VII+492, figs. 357).—Practical information is presented on the construction, operation, and repair of farm tractors.

Electric tillage (*Impl. and Mach. Rev.*, 58 (1932), No. 692, pp. 631-633, figs. 2).—A brief report is presented of field tests of a new electric tractor. This tractor consists primarily of an angle iron frame supported mainly by two broad drum wheels, inside each of which is attached a powerful motor, which is suspended from the axle and drives the wheel. A smaller stub frame is offset to the main frame and forms the mounting for a winding drum to carry the cable. A multiple-furrow plow is attached to the front and rear, making the outfit a 1-way plowing unit that avoids all open furrows.

Power is fed from the 3-phase wiring system by attaching a trolley pole to the four wires. The pole is fitted with runners to permit it to slide along rapidly. The current is subject to the operation of a main switch on the tractor and is further controlled for individual duties by other switches.

Cultivation of ratoons under unirrigated conditions on Kauai. W. P. ALEXANDER (*Assoc. Hawaii. Sugar Technol. Rpts.*, 11 (1932), pp. 3-30, figs. 34).—This is a technical discussion of standard practices in the cultivation of ratoon cane on the unirrigated lands of Kauai. The machinery and equipment used are profusely illustrated, special attention being drawn to deep tillage and pulverizing devices.

Cultivation on unirrigated plantations on the island of Hawaii. R. BRYAN (*Assoc. Hawaii. Sugar Technol. Rpts.*, 11 (1932), pp. 31-35, figs. 6).—A

brief description of cultivation practice on unirrigated plantations on the island of Hawaii is presented, and the cultivating machinery used is illustrated. It is pointed out that the machinery and methods used are adapted primarily to the interests of better weed control.

A combine reel for harvesting peas, E. N. HUMPHREY (*Agri. Engin.*, 13 (1932), No. 12, pp. 316, 317, figs. 4).—A new rake reel developed at the Idaho Experiment Station and which promises to materially reduce shattering and field losses in the combining of peas is described and diagrammatically illustrated. The mechanism has the appearance of an enlarged side-delivery rake reel mounted on the header platform.

Grinding and elevating grain with one-half h.p. motor, H. J. GALLAGHER (*Michigan Sta. Quart. Bul.*, 15 (1933), No. 3, pp. 146-151, figs. 3).—Practical information and working data are given on the subject.

Filling silos with the field ensilage harvester, A. J. SCHWANTES and J. B. TORRANCE (*Minnesota Sta. Bul.* 290 (1932), pp. 27, figs. 6).—The results of a study of field silage harvesters are reported which included 14 machines used on 35 farms. Two and one half farms and 37.3 acres was the average per machine in 1930. A capacity of about 7.5 tons, or about 1 acre per hour, might reasonably be expected under normal conditions. In most cases one man handled the silage harvester and the tractor or horses. An average of 3.6 men were employed hauling the silage from the field to the silo. On most farms one man remained at the silo to assist in unloading. In about one third of the cases a man worked in the silo.

Four teams were used for hauling silage on one half of the farms. On about one third of the farms three teams were used. The power unit for operating the blower may be smaller than that required to operate a stationary silo filler. In the field a 3-plow tractor is needed to operate the field silage harvester. This is more than is necessary for the corn binder.

The average estimated life of the field silage harvester was 10.8 years and of the blower 20 years. The total cost per acre of filling silos with the field silage harvester is \$7.83 and the cost per ton is \$1.07, based on a yield of 7.3 tons per acre and a charge of 30 c. per hour for man labor and 12.5 c. per hour for horse work. The cost of operating a 2-plow tractor was assumed to be 74 c. per hour and that of a 3-plow tractor 96 c. Labor costs are somewhat less with the field silage harvester method of filling silos than with the stationary silo filler method, but power and machinery costs tend to be about the same. There is no significant difference in total costs of the two methods. The field silage harvester equipment requires a cash lay-out about 27 percent higher than that for the corn binder and silo filler.

Dairy manufacturing machinery, B. LICHTENBERGER (*Lehrbuch der Milch-wirtschaftlichen Maschinenkunde*. Hildesheim: Molk.-Ztg., 1932, pp. 370, pls. 31, figs. 185).—This book, which is written from the German viewpoint, brings together a large amount of information relating to machinery and equipment used in dairying and in dairy manufacture and discusses the design and development of such equipment for specific purposes.

Modern farm buildings, D. N. McHARDY (*London: Crosby Lockwood & Son*, 1932, pp. XII+227, figs. 85).—The subject matter of this book falls into two sections, in the first of which the principles of construction are described in nontechnical language. The second section deals with the principles of design applicable to the various classes of buildings. Chapters are included on plan drawing; concrete; concrete construction; brickwork; roofing materials; carpentry and joinery; drainage; water supply; lighting; business considerations; cowsheds; dairy buildings; housing dry cattle; stables, cart, and implement sheds; construction of piggeries; food supplies and crop storage;

miscellaneous structures; modernizing old buildings; repairs and upkeep; form of contract agreement; and specification. An appendix contains cost and dimension estimates.

Greenhouses and hotbeds, F. BÖHMIG (*Gewächshäuser und Frühbeete. Berlin: Paul Parey, 1932, pp. VIII+193, figs. 169*).—This book gives both practical and technical information on the design, construction, and use of greenhouses and hotbeds and describes equipment such as heating plants and facilities for watering. It is based entirely on German practice and experience.

Greenhouse heating, A. H. SENNER (*U.S. Dept. Agr. Circ. 254 (1932), pp. 40, figs. 26*).—This circular gives technical information relating to the design and improvement of greenhouse heating plants. It presents standard engineering data on the subject together with practical information on the lay-out and operation of modern greenhouse heating systems.

The experimental use of artificial light in connection with the growing of cucumbers in Denmark, E. SROUD (*Illum. Engin., 25 (1932), May, pp. 123-125, figs. 7*).—The results of experiments to determine the most economical intensity of illumination for cucumbers are reported. The experiments involved the use of test fields in a line occupying a space about 35 ft. long by 6 ft. wide, two at one end using 500-w lamps in intensive prismatic reflectors, two at the other end using 750-w lamps in similar prismatic reflectors, and a center space without artificial light. The reflectors were covered so that all the light was emitted in a zone of 55°. The height of the units above the new plants was 1.325 m (4 ft. 4 in.), and the position of the lamp in the reflector was such that very little light was emitted outside the test fields.

It was found that not only did the light have no prejudicial effect on the plants, but that those illuminated had greener leaves and a greater leaf area. This, in conjunction with the longer (artificial) day, created greater assimilation, and thus contributed to a more robust development of the root. The illumination therefore furnished a plant in quick and continuous development, which does not stagnate and is more capable of resistance against diseases. A natural consequence is that it becomes less necessary to plant more seeds than precisely those required to furnish the quota of plants, which means a saving in seeds, space, and attention. The plants which were exposed to artificial light maintained throughout the lead they had originally gained.

The conclusion is drawn that the illumination yielded by the 500-w lamps was apparently sufficient. No very material advantage was shown in the behavior of plants in the area lighted by 750-w lamps.

The ventilation of animal shelters, F. L. FAIRBANKS (*Agr. Engin., 13 (1932), No. 12, pp. 321-323, figs. 4*).—This is a brief description of the research procedure followed in the study of the ventilation of animal shelters at the New York Cornell Experiment Station and a summary of the main findings. The dairy stable ventilation standards tentatively established are (1) the temperatures in the stable should be from 45° to 50° F. with an allowable variation of $\pm 10^\circ$, (2) the relative humidity should be about 75 percent and not over 85 percent, (3) the air flow into and out of the stable should be from 50 to 60 cu. ft. per minute per cow and may vary from 40 to 80 cu. ft. per minute per cow in extreme cases, and (4) the internal air movement or convection currents should be positive at all times; that is, they should be constantly in operation in a certain direction to insure a complete mixing of the stable air with the fresh air in order to produce uniform temperature and humidity and air movement conditions throughout the stable, to act in the capacity of a partial insulation as they pass down the outside walls, and to evaporate superexcess moisture which appears in windows and to some extent on walls and intakes during extensive cold periods.

Good poultry equipment—one of the short cuts to greater poultry profits, J. M. MOORE (*Michigan Sta. Quart. Bul.*, 15 (1933), No. 3, pp. 197-204, figs. 11).—Various types of poultry equipment are described and illustrated, including mash hoppers, watering equipment, shades, and catching crates.

The artificial lighting of poultry houses, R. T. PARKHURST (*Scot. Jour. Agr.*, 15 (1932), No. 4, pp. 422-426).—Studies conducted at the National Institute of Poultry Husbandry in Scotland are reported in which different lighting arrangements were tested.

The morning and evening system of lighting increased the production and income, provided absolute regularity from autumn to spring, and divided the discharge of the batteries between night and morning, thereby lightening the load on the generator. The all-night lights gave disappointing results, although in the long run they were superior to all others for hens.

Experiments with electric water heaters for poultry, T. E. HIENTON and C. W. CARRICK (*Indiana Sta. Bul.* 367 (1932), pp. 12, figs. 7).—Experiments are reported which showed that electric heaters of proper capacity offer a satisfactory method for preventing freezing in poultry drinking vessels. An electric heater of more than 30-w capacity was required to prevent freezing in a 14-qt. bucket at temperatures below 15° F., under conditions prevailing during the tests. An 8-gal. fountain required a heater of more than 75-w capacity to prevent freezing in zero weather or below. Water in similar vessels froze at higher temperatures with external heaters than with immersion heaters of the same wattage. External heaters equipped with 3-heat switches used less total current than did immersion heaters having the same wattages as those of the former at high heats. Fountain warmers should be slightly larger than the bases of the fountains which they heat to prevent freezing of water in the troughs.

Some factors affecting mechanical refrigeration for dairy farms, T. E. HIENTON and E. H. PARFITT (*Indiana Sta. Bul.* 363 (1932), pp. 8, figs. 3).—Studies are reported which showed that the average current consumption for 100 lb. of milk cooled per degree F. by three dry-box type milk-cooling installations operated for one year was 0.064 kw.-hr. The average current consumption for cooling 100 lb. of milk by two storage-tank type milk-cooling installations operated for more than one year was 0.041 kw.-hr.

Heat losses in B.t.u. per 24 hours per square foot per degree temperature difference varied from 4.24 to 2.13 in five insulated milk tanks studied. Heat losses are dependent upon the amount of insulating material used in the construction of the storage box.

Of the temperatures studied, 45° was found to be the most satisfactory at which to operate a milk-cooling tank to inhibit bacterial development during a storage period of from 12 to 14 hours. Precooling of milk over a surface cooler to 70° was found to show no bacterial advantage when compared with milk not surface cooled but placed immediately in the cooling tank, but did result in less use of energy by the refrigeration unit. Agitation of the cooling medium in a wet storage tank by means of a mechanical agitator increased the rate of cooling of milk not surface cooled but caused no significant difference in the bacterial count of the milk from that cooled in tanks not agitated. The rate of cooling was faster with the use of a surface cooler than where milk, not surface cooled, was cooled in the tank and the cooling water agitated for 2 hours, but there was no significant difference in bacterial counts.

Testing of the fire resistance of building materials and structures, II, III [trans. title], R. SCHLYTER and C. MÖLLER (*Statens Provvningsanst., Stockholm, Meddel.* 57 (1932), pp. [3]+71, figs. 49; *Eng. abs.* pp. 62-67).—In a fur-

ther contribution to the subject (E.S.R., 66, p. 580), rules are presented for the fire-testing and classification of building materials, elements of structures, and the like, and the results of tests of partition walls of wood, protected by paneling, reeding, and plastering on both sides, and unprotected, are reported. Six wall types were tested, including reeded and plastered wooden walls, partition walls of 5-cm planks unprotected, partition walls lined with asbestos and sheet metal, partition walls lined with asbestos-cement sheets, partition walls lined with Gyproc sheets, and partition walls lined with Kivron sheets. The temperature of the experimental furnace was about 750° C. after 15 minutes.

The results showed that reeds and plaster, Gyproc, Kivron, and asbestos-cement sheets protect the wooden body of a wall against fire for about 15 to 20 minutes. The protective capacity of the thinner materials was generally limited to 5 minutes. It is concluded that partition walls should be faced on both sides.

Prevention and control of farm fires, edited by A. SECOR (*Chicago: [I. D. Goss], 1932, pp. XII+13-167, figs. 12*).—This is a handbook on the causes of fires and on the best methods of safeguarding against loss of life and property through them. Special attention is drawn to the fact that good construction is an aid to the prevention and control of farm fires. Other fire-protection methods are discussed.

AGRICULTURAL ECONOMICS

[Investigations in agricultural economics at the Delaware Station, 1931-32] (*Delaware Sta. Bul. 179 (1932), pp. 6-11*).—Results of investigations not previously noted include data on the financing of education in Delaware by M. M. Daugherty, showing the expenditures for education from local and State funds in 1910, 1915, 1920, 1925, and 1930, and the relative rank among the States of the Delaware school system in 1918, 1920, 1922, 1924, 1926, 1928, and 1930; and findings by H. S. Gabriel as to the acreage, varieties, and prices of and markets for early apples grown in Delaware, and by R. O. Bausman as to labor income and the cost of producing eggs, pullets, baby chicks, and broilers in a study of 115 poultry farms for the year ended September 30, 1931.

[Investigations in agricultural economics at the Indiana Station, 1931-32] (*Indiana Sta. Rpt. 1932, pp. 39-41, fig. 1*).—Brief summaries of results of studies not previously noted are included as follows: Farm layout in its relation to fencing costs and farm organization; human factors in farm management, made in cooperation with the Bureau of Agricultural Economics, U.S.D.A., and based on data regarding 183 farmers; the validity of certain measures of farm operating efficiency based on 280 records in the central part of the State; costs and incomes of 34 local grain elevators in western Indiana during the crop year 1930-31; labor income on 22 farms operated chiefly with mechanical power; cost of husking corn during the 1931 season on 21 farms using 1-row and 41 farms using 2-row pickers; and the consumption of electricity on farm operations.

[Investigations in agricultural economics at the Iowa Station, 1931-32] (*Iowa Sta. Rpt. 1932, pp. 8-15*).—Investigations not previously noted are reported on briefly as follows: Elasticity of Supply of Corn and Hogs for the Different Types of Farming Areas of Iowa, by T. W. Schultz and A. G. Black; Stock-Share Farm Leasing, by M. Peck; Packer Demand for Iowa Hogs, by P. L. Miller, I. W. Arthur, and M. D. Helser, including data on reshipments at terminal markets for slaughter; Destination and Origin of Iowa's Commercial Corn and Oats, by R. C. Bentley and P. L. Miller, summarizing findings for

the years 1923-24 to 1929-30, inclusive; Secular, Annual, and Monthly Movements in the Price of Cash Corn, by G. S. Shepherd; Iowa Farm Land Values, by M. Peck; Seasonal Fluctuations in Marketing Iowa Hogs, by P. L. Miller; The Place of Pasture in Iowa Farming Types, by A. G. Black, C. L. Holmes, E. B. Hurd, and H. D. Hughes, including data showing the relation of topography and soil type and the percentage of land in pasture; The Utilization and Cost of Farm Power, by A. G. Black, J. A. Hopkins, Jr., A. B. Caine, and J. B. Davidson, including findings on the profitableness of the use of mechanical corn pickers in 1931; and Recent Trends and Present Status of Farmers' Elevators, by F. Robotka.

[Investigations in agricultural economics and farm management at the New York Cornell Station, 1931-32] (*New York Cornell Sta. Rpt. 1932, pp. 80-89*).—Results of investigations not previously noted are reported as follows: Factors affecting the cost of production and returns per hour of labor in growing potatoes, found in a study of F. L. Underwood; the average labor incomes in 4 counties found by L. C. Cunningham in a study of dairy management; data regarding the distribution of grapes grown in different States, the cost of packing grapes in central New York and the Chautaugua-Erie grape belt and of distribution in Philadelphia and Chicago, and returns to country shippers for U.S. No. 1 and ungraded Concord and ungraded Niagara grapes, found in a study made by M. P. Rasmussen of the marketing of eastern grapes, in cooperation with the U.S. Department of Agriculture and the Federal Farm Board; and some findings of Rasmussen in a study of the marketing of New York potatoes and of W. C. Hopper in a study of public produce markets in New York.

Included are some brief findings of G. F. Warren and F. A. Pearson in studies of the physical volume of production of agricultural and other products, of the purchasing power of wages, and of debts in the United States, of gold and prices, of efficiency in the use of gold, and of world gold production and world monetary stocks of gold.

Brief reports are made of the study of index numbers of prices at New York, 1720-1800, by H. M. Stoker; and of the findings as to grades, prices received for different grades, and factors affecting consumer's preferences, in a study by A. R. Gans of the relation of price to the quality of eggs in New York City; of relative average assessed value of land per acre, tax delinquency, and school enrollment in rural schools in different land-class areas, as found by A. B. Lewis in a study of land utilization in Tompkins County; and of the sources of short-time and mortgage credit of New York farmers, found in a study by G. W. Hedlund.

[Investigations in agricultural economics of the Ohio Station, 1931-32] (*Ohio Sta. Bul. 516 (1933), pp. 96, 97, 98-100*).—Results of investigations not previously noted are reported, included data as to the changes from 1925 to 1929 in the total volume of agricultural production, physical volume of sales, and farm population of the State, by J. I. Falconer; a table by H. R. Moore and F. L. Morison showing the average property taxes per farm and the number of bushels and acres of wheat required to pay such taxes in 1919, 1920, and the years 1927-32; a table by C. G. McBride and R. W. Sherman showing the 1930 population of 8 population centers of the State, the number of farms under board of health inspection, and the ratio of population to number of inspected farms in the milk sheds of the 8 population centers; a table by G. F. Henning showing the trucking area, in square miles, from which truckers obtain 50 percent of their volume in 4 selected areas of the State; and a table by C. W. Hauck showing the retail sales at roadside markets of various types.

[Investigations in agricultural economics of the Ohio Station] (*Ohio Sta. Bmo. Bul.*, 18 (1933), No. 2, pp. 55-59, fig. 1).—Of the three articles here included, Rural Ohio's Contribution to Road Finance, by J. F. Dowler, contains a table showing for 1931 the tax revenue collected for roads by different levying jurisdictions and other data. Trends in Farm Taxes, Prices of Farm Products, and Farm Real Estate Values, by H. R. Moore, shows by a chart the annual indexes of farm taxes paid and the prices of farm products and of farm real estate in Ohio, 1900-1932. Index Numbers of Production, Prices, and Income, by J. I. Falconer, brings the data previously noted (*E.S.R.*, 68, p. 840) through December 1932.

The value of crop rotation in the Coastal Plain area, R. H. ROGERS and H. B. MANN (*North Carolina Sta. Bul.* 280 (1933), pp. 31, fig. 1).—Experimental results obtained at the Upper Coastal Plain Substation from 1924 to 1931, inclusive, with a 2-year rotation of corn and cotton (system 1), and a 4-year rotation of corn, rye, cotton, and oats and vetch hay, there being an acreage of each crop each year (system 2). A third system is also presented consisting of the 4-year rotation with livestock and a garden added. Using fields of 10 and 20 acres as a basis, tables are given showing for the three systems illustrative cropping plans, yields, rates of seeding, fertilizer used, disposal of crops, labor requirements, inventories, and receipts, expenses, and return on investment. Some suggestions are made for changes in the 2- and 4-year rotation plans and for other rotations as follows: Two-year rotation of tobacco and cotton including winter cover crops, 3-year rotation with tobacco, corn, cotton, soybeans, peanuts, and cover crops; 4-year rotation with tobacco, corn, cotton, soybeans, and cover crops; and 2-, 3-, 4-, and 5-year general rotations with corn, soybeans, small grains, cotton, lespedeza, and cover crops.

Findings as to the three systems were as follows: Average inventory valuation (1) \$4,035, (2) \$4,130, and (3) \$5,821; receipts, (1) \$653, (2) \$822, and (3) \$1,258; expenses, including decrease in inventory on unpaid family labor and operator's labor, (1) \$792, (2) \$649, and (3) \$968; value of produce for family living produced on farm, (1) and (2) \$20, and (3) \$440; and amount available for luxuries, improvements, savings, etc., (1) —\$335, (2) —\$50, and (3) \$197.

Factors in the organization and successful operation of Louisiana rice farms, 1930, R. J. SAVILLE (*Louisiana Stas. Bul.* 233 (1933), pp. 51, figs. 7).—This bulletin analyzes the financial results of the farm business and the costs of producing rice in 1930 on 302 farms in the prairie rice section of Louisiana. Charts show the relation of the prices, 1921-30, of rough rice and cotton and all commodities, and of the prices, 1913-30, of rough rice and rice farm machinery and Louisiana farm wages. Tables show the average (farms usually grouped by size) animal units of livestock, investment by items, receipts, total expenses, and cash expenses, and the labor income, 1929 and 1930. The effect of size of business, crop yields, labor efficiency, balance of farm business, and cost of producing rice on labor income, and the relation of yields and acreage of rice and cost of production are discussed. Other tables present data as to costs of irrigation, use of tractors, and truck and automobile operation.

Of the average gross receipts of the farms, 92 percent was from rice sales. Cotton sales comprised 97 percent of the balance and livestock \$160 per farm. Labor income averaged —\$256, that of about 50 percent of the farmers being between +\$500 and —\$500, and that of 85 percent between +\$1,500 and —\$1,500. In 1930, 41 percent of the farmers had plus labor incomes as compared with 89 percent in 1929. The average rent for rice land, based on cash share rentals, was \$6.75 per acre. Full-owner operators had a farm rental equivalent of \$3.21 per acre, of which \$1.80 was needed to pay taxes.

Rate of crop production was the most important factor affecting labor income in 1930. Size of business was not so significant as usual in 1930 unless combined with better than average conditions of yield, price, and labor efficiency. Farmers obtaining all of their gross receipts from rice did not receive as high average labor incomes as those obtaining part of their receipts from other sources.

The average cost of producing rice was \$3.57 per barrel, of which 56 percent was current cash outlay, 12 percent interest, depreciation, and unpaid family labor, 16 percent land rent, and 16 percent operator's wage and management charge. Irrigation outlay of private plants was materially lower than competitive water rents only for Diesel engine plants flooding 225 acres or more. Paying cash water rent was profitable only when rice yields were above the average.

Organization and management of Maryland farms: Piedmont Plateau region, S H. DEVAULT and R. HURLEY (*Maryland Sta. Bul. 337 (1932), pp. 155-212, figs. 10*).—The results are presented of a farm management study including 282 farms in 1928, 270 farms in 1929, and 279 farms in 1930, of which 52 percent were dairy, 20 percent general, 16 percent cash crop, 6 percent poultry, and 6 percent livestock farms. The region and agricultural conditions during the three years are described. Analysis is made of the effects of type of farming, size of business, crop yields and animal production, efficiency of operation, combination of the above factors and materials of production, and the selection and combination of enterprises on farm profits upon the farms as a whole and for each type of farm. Some examples of successful farms are described. Recommendations are made for improvements in organization and management of farms in the area.

The average labor incomes for all farms were in 1928, \$652; 1929, \$156; and 1930, —\$559. The percentages of farms having plus labor incomes in the respective years were 64.2, 57.8, and 36.9. The 3-year averages for the different types of farms were for dairy farms \$318, general \$174, cash crop —\$647, poultry \$492, and livestock —\$745.

The most profitable farms were somewhat larger than the average, their yields of crops were from 20 to 25 percent above the average, the animal production per unit usually one third above the average, and the labor expense per \$100 of receipts less than 50 percent of that on the least profitable farms. The more efficient operators economized in the use of purchased feed, fertilizer, and lime, and used more machinery and less labor on the same area. There was evidence that labor income decreased as the amount of feed purchased per cow increased.

"Opportunity for making the largest profit appears to be in adapting a system of farm organization that includes one major enterprise, suited to conditions on the individual farm, and one or more minor supplementary enterprises. Each of these should be large enough to permit of efficiency in operation, and they should be so combined as to provide full-time employment for the farm operator, his family, and hired labor. Such a system provides also for the maintenance of soil fertility and the economical utilization of the by-products, such as straw, corn stover, etc."

Economic efficiency of the farm layout in Maryland, A. B. HAMILTON and S. H. DEVAULT (*Maryland Sta. Bul. 338 (1932), pp. 213-260, figs. 36*).—"This bulletin reports the results of a study of the layouts of 127 Maryland farms, the object being to trace the development of farm layouts, to measure the relative efficiency of different farm layouts from the standpoint of conveyance used

in getting from the house to the different parts of the farm, to study the arrangement of the farmstead, to determine the economic loss in haying small, odd-shaped fields, and to measure the efficiency in the use of labor and machinery on large and small farms as well as on fields of different size and shape."

Factors to be considered in locating and planning the farmstead and such factors in planning fields as size, shape, obstructions, and type of fences are discussed. Maps show examples of existing good and poor layouts. The rearrangement of three existing farms is shown and discussed.

Following are some of the findings regarding the 50-acre and less, 101- to 150-acre, and of farms over 200-acre groups, respectively: Total capital invested \$7,053, \$16,686, and \$30,881; percentage of total capital in land 32.3, 47.1, and 55.5, in dwellings 30.5, 16.4, and 10.6, in other buildings 21.8, 18.2, and 13.7, in livestock 12.4, 14.2, and 17.6, and in machinery 3, 4.1, and 2.6; size of farmed fields 5.8, 16, and 34.4 acres; number of cropped acres 27.4, 96.5, and 212.2; acreage of crops per man 21, 42, and 76; average distance from barn to cropped fields 149.4, 228.8, and 230 yd.; and value of machinery per cropped acre \$7.89, \$7.30, and \$3.90.

Some of the findings regarding the farms grouped as having good, fair, and poor layouts were, respectively, as follows: Average labor income in 1929 \$1,753, \$1,032, and \$133, and in 1930 \$294, —\$0.50, and —\$338; total acreage 143, 132, and 156; crop acres 112, 106, and 102; value of machinery per crop acre \$5.59, \$4.39, and \$4.16; size of fields 17.3, 16.9, and 14.3 acres; crop acres per worker 57.3, 55.4, and 47.4; distance to fields 193, 209, and 224 yd.; and size of farmstead 1.4, 2.6, and 3.2 acres.

The effect of certain farm practices on crop and livestock returns on central Michigan farms in 1931. P. F. AYLESWORTH and E. B. HILL, (*Michigan Sta. Quart. Bul.*, 15 (1933), No. 3, pp. 160-166).—The data were obtained from 268 farmers keeping financial records on survey blanks containing questions on the approved practices outlined by the Michigan State College. Analysis is made of the data from 80 medium-size farms (from 85 to 125 tillable acres). Tables show for the 20 high and the 20 low farms the crop practices (farms sorted on the basis of crop production per acre), dairy practices (farms sorted on the basis of dairy sales per cow), and poultry practices (farms sorted on basis of egg sales per hen). Other tables show the effects of six crop practices on the value of crops per tillable acre, of eight dairy practices on the value of dairy sales per cow, of seven poultry practices on the value of egg sales per hen, and the combined effect of different numbers of such practices used on the returns from the enterprises.

Changes in farming in Lake and Porter Counties, Indiana, as a result of nearness to industrial cities. L. ROBERTSON (*Indiana Sta. Bul.* 365 (1932), pp. 20, figs. 12).—This bulletin is based on data for 1920 and 1930 for 60 farms in Lake and Porter Counties and 65 farms in Clinton County, a county about 90 miles farther south in the State but comparable as to climate, soils, etc. Tables are given and discussed showing per farm for the 2 areas for the 2 years the average number of livestock of different kinds; average crop acreages; the crop, dairy, hog, and poultry practices; and data as to power, labor, machinery, fencing, and home conveniences.

The nearness of Lake and Porter Counties to the heavily populated industrial region has resulted in improved markets for milk, poultry products, fruit, and vegetables; has increased labor costs and problems and farm land prices and taxes; and has impeded farm improvements and detracted from rural community life. It is largely responsible for the dairy type of farming in northwestern Indiana and the emphasis on poultry production instead of on the production of hogs, sheep, and beef cattle. Fewer crop equipment changes were made on

Lake and Porter County farms than on farms in central Indiana, and crop production per worker increases were greater than in the latter section.

The agricultural emergency in Iowa, I-VI (*Iowa Sta. Circs. 139 (1932), pp. 8; 140, pp. 9-23; 141, pp. 25-38; 142 (1933), pp. 41-55, figs. 4; 143, pp. 57-71, fig. 1; 144, pp. 73-104, figs. 5*).—This series of circulars discusses the various phases and causes of the agricultural situation in Iowa and some remedies proposed.

Part 1, the situation today, by A. G. Black, outlines the existing conditions. Part 2, by G. Shepherd, discusses the causes of the emergency. Part 3, by T. W. Schultz and Black, points out the essential features of the voluntary domestic allotment plan for certain agricultural products as contained in the Norbeck-Hope bill pending in Congress. Part 4, by W. G. Murray and R. C. Bentley, on the Iowa farm mortgage situation, is a revision of the report previously noted (*E.S.R.*, 58, p. 381). New data are presented and the statistical series brought up to October 13, 1932. Part 5, by Shepherd and W. Wright, discusses general price control, the need for such control, and what the Federal Reserve System has done to check deflation. Part 6, by J. A. Hopkins, Jr., deals with the tax situation in the State, discussing the receipts and expenditures for different purposes and the indebtedness of different governmental units.

Emergency farm adjustments in the wheat area of South Dakota, R. S. KIFER, P. CHRISTOPHERSON, and S. E. JOHNSON (*South Dakota Sta. Circ. 8 (1933), pp. 25*).—This circular, prepared in cooperation with the Bureau of Agricultural Economics, U.S.D.A., describes what some farmers in the spring wheat section of South Dakota have done to reduce expenses or shift production to make their incomes equal expenses. The adjustments to reduce expenses are illustrated by a livestock farm, and those to make better use of equipment and labor and to adjust indebtedness, those taking into account changes of ownership, those on a rented farm, and those on a farm with no indebtedness are illustrated by data for individual farms.

The adjustments have taken the form of reduced cash expenses; reduction of capital assets; using family labor and equipment to the limit of capacity; increase of acreage of cash grain in some cases at the expense of feed grains, legumes, and a long-time advantageous cropping system; shifting herds of stock cattle to dairy production; shifting from a conservative production program to a more speculative one of feeding livestock; and, in extreme cases, the relinquishment of title to farms and continuing operation as tenants.

A review of the accuracy and timeliness of outlook statements, C. O. YOUNGSTROM (*Idaho Sta. Circ. 62 (1932), pp. 28, fig. 1*).—Tables are included showing for potatoes, wheat, clover and alfalfa seed, beans, sheep, beef cattle, dairying, poultry and eggs, and hogs, by years beginning 1924 to 1926 to 1931, inclusive, extracts from the annual outlook reports of the Bureau of Agricultural Economics, U.S.D.A., and the average Idaho farm price of the products for the year to which the forecasts pertain. The outlook reports available are discussed and the dates of issuance given.

"A review of the first six annual outlook reports indicates that they ranged from 84 percent to as high as 94 percent correct. This is in substantial agreement with the review presented in this circular."

The agricultural outlook for 1933 (*U.S. Dept. Agr., Misc. Pub. 156 (1933), pp. 99*).—This report, which continues the series previously noted (*E.S.R.*, 67, p. 181), was prepared by the staff of the Bureau of Agricultural Economics, assisted by representatives of the State agricultural colleges and extension services and the Federal Farm Board. It "summarizes facts, not readily avail-

able to farmers, on the supply, demand, and price aspects of the principal crops and classes of livestock. These facts are analyzed and interpreted so far as possible to show the probable trend of conditions during the coming year in order to aid farmers in making plans for the season's operations. The statements are necessarily general in nature, because this report is prepared from the national viewpoint." Domestic demand, foreign competition and demand, agricultural credit, farm labor, equipment, and fertilizers, farm family living, the outlook during 1933 for different crops and different classes of livestock and livestock products, and the long-time agricultural outlook are dealt with.

Agricultural outlook for Illinois, 1933 (*Illinois Sta. Circ. 402 (1933), pp. 40, figs. 9*).—This circular discusses the general agricultural situation and the outlook for 1933 for feed crops, hay, feedstuffs, different field crops, different kinds of livestock and livestock products, fruits, vegetables, and forestry.

Farmer opinions and other factors influencing cotton production and acreage adjustments in the South, T. B. MANNY (*U.S. Dept. Agr. Circ. 258 (1933), pp. 42*).—This circular reports the results of a study in which 834 farmers in 11 counties of the Mississippi Delta, the Piedmont, and the South Atlantic Coastal Plain cotton-growing areas were interviewed. Its objectives were "(1) to note recent changes in acreage planted to cotton and to other important crops. (2) To learn the reasons given by farmers for planting the specific acreages they did. (3) To determine, if possible, the premises upon which these farmer decisions were based and the sources of information used in arriving at decisions of this kind. (4) To note the extent to which interviewed farmers received and utilized the outlook information prepared and distributed by Federal and State agencies. (5) To note general differences as regards the acreage adjustments between farmers as classified by various factors such as size of farm, tenure, schooling, length of farm experience, etc. (6) To discover the chief sources of resistance to adjustments in the farm business, especially sources that are not exclusively economic in character."

The annual changes in cotton acreage, 1926-31, and the reasons for the changes; the influence of the 1930 price of cotton, credit, and the attitude of local business men on the 1931 acreage; the influence of long-time farming plans, short-time considerations, tenure, size of farm business, and schooling of farm operators on acreage adjustments; the adjustments in fertilizer use, 1928-31; the sources of economic information regarding cotton and the use made of such information; and the production of crops other than cotton are discussed. Some observations based upon enumerators' notes are made on the effect of material changes in the cropping system on the economic and social structure of the cotton areas, the cropper problem, the climate, and production credit.

The study showed the need and opportunity for more ingenuity in meeting farm management problems; a hopeful movement toward the home growing of feeds and foods; that acreage adjustments are based too much on retrospect and too little on current conditions or prospects; a recognition by many farmers that there are some opportunities to replace cotton with other crops or farm enterprises; a commendation by the more progressive farmers of the live-at-home campaigns of the extension services; that the live-at-home goal is the most effective means of encouraging cotton acreage adjustments; that members of cooperative cotton-marketing associations are decidedly more likely to use economic information as a basis of adjustments than are non-members; that a majority of the farmers rely on daily papers for economic information, but many are unable to interpret it and the information is not

always sufficient to give an adequate understanding of current conditions; that home economists can render a valuable service in encouraging rational adjustments in the farm business; and that any attempt to stimulate more rational planning and management on individual farms must take into account not only economic factors but also social and psychological factors.

Foreign government legislation affecting wheat, G. P. BOALS (*U.S. Dept. Agr., Bur. Agr. Econ., Foreign Serv. Rpt. 58 (1932), pp. 54, fig. 1*).—Legislation in effect in 1932 in the several countries of the world is briefly discussed.

The domestic allotment plans for the relief of agriculture: Selected references, compiled by L. O. BERCAW (*U.S. Dept. Agr., Bur. Agr. Econ., Agr. Econ. Bibliog. 41 (1933), pp. 11+[51]*).—This mimeographed bibliography includes 191 selected references on the allotment plans advocated. Most of the references are to publications during 1932 and 1933.

The farm real estate situation, 1931-32, B. R. STAUBER (*U.S. Dept. Agr. Circ. 261 (1933), pp. 51, figs. 11*).—This circular continues the study previously noted (*E.S.R.*, 67, p. 80) and covers for most of the data the year ended March 1, 1932.

The index of estimated value per acre of farm real estate (1912-14=100) decreased from 106 of the previous year to 89. The decreases in the different geographic divisions of the United States were for New England from 126 to 116, Middle Atlantic 101 to 96, East North Central 87 to 73, West North Central 97 to 81, South Atlantic 116 to 96, East South Central 117 to 97, West South Central 121 to 97, Mountain 100 to 82, and Pacific from 140 to 118.

Maps based on the 1930 Federal census reports are included and discussed showing on April 1, 1930, on a county basis the value per acre of farm real estate and of farms, including land, buildings, livestock, and equipment, and by States the value of farm dwellings on April 1, 1930, and the percentage change, 1910-30, of the aggregate value of farm real estate.

Gross income from farm production in 1931 declined 26 percent from 1930, being practically the same as for 1913 and \$2,000,000,000 lower than the low point of the 1920-21 depression. The price indexes in March 1932 for farm products were below the 1910-14 average by the following percentages: Grain 49, meat animals 31, cotton and cottonseed 50, dairy products 24, poultry products 39, and fruits and vegetables 27. The index of prices of commodities used in production was 12 percent, and that for commodities used for consumption 15 percent, above the 1910-14 average.

The number of farms changing ownership by voluntary sales and trades decreased from 19 per 1,000 for the year ended March 15, 1931, to 16.2 per 1,000 for the year ended March 15, 1932. The changes due to delinquent taxes increased from 7.4 to 13.3, and those due to foreclosure of mortgages, bankruptcy, etc., increased from 18.7 to 28.4 per 1,000. In the East North Central States, voluntary sales dropped from 18.6 to 16.8 farms per 1,000, sales by reason of tax delinquency rose from 4.7 to 6.5, and transfers due to mortgage foreclosures, bankruptcy, deeding back, and related defaults increased from 19.3 to 27.8 farms per 1,000. In the West North Central States, the changes were from 18.9 to 14.2, from 5.5 to 8.7, and from 25.8 to 43.8 per 1,000 farms, respectively.

Farm mortgage credit and farm real estate taxes are discussed briefly.

“Significant among the developments in the farm real estate situation during the year 1931-32 have been the greatest declines in values since 1921-22, a further substantial increase in the number of distress sales, a continued decrease in the number of voluntary sales, a continuation of the movement to farms on the part of unemployed, and further extension of a policy of leniency

toward foreclosing on the part of loaning agencies. These developments are associated with the continued decline in the price level which has accompanied the depression, and which has reduced gross income from agricultural production to very near the pre-war level. Fixed charges based upon previous valuations have augmented the depressing effects of reduced income."

An analysis of the loaning operations of the Federal Land Bank of Springfield from its organization in March, 1917, to May 31, 1929, F. F. HILL (*New York Cornell Sta. Bul. 549 (1932), pp. 107, figs. 4*).—The data presented are from a statistical study of the bank previously noted (*E.S.R.*, 65, p. 682), and the discussion is centered around the bank's loaning operations in New York. The distribution of loans, foreclosures and losses, the sale of acquired farms, and the foreclosures among loans made by different appraisers are discussed. Analysis is made of the relation between foreclosures and soils, appraised value per acre of the farm and per acre of the tillage land, elevation, location relative to markets, type of road and distance to market, appraised value of farm buildings, acreage in farms, type of farming, place of origin and previous farming experience of borrowers, age of borrowers, transfers of loans, borrower's equity in the farm, manner in which farm was acquired, and the year in which the loan was made.

An appendix includes a brief description of the organization of the Federal land bank system, tables showing the location and territory of the 12 Federal land banks, amortization and miscellaneous tables, and the tabulating card forms and appraisal form used by the Federal Land Bank of Springfield (Mass.).

An economic analysis of farm mortgages in Story County, Iowa, 1854–1931, W. G. MURRAY (*Iowa Sta. Res. Bul. 156 (1933), pp. 361–423, figs. 12*).—In this study made in cooperation with the U.S.D.A. Bureau of Agricultural Economics, analysis was made of all the mortgages placed on farm lands in the county from 1854 to 1931, inclusive. The trend of the mortgage debt during the periods of land settlement, 1854–79, of rising land values, 1880–1910, of price inflation, 1911–20, and of price deflation, 1921–31; the short-time changes, including the purpose of loans, foreclosures, and the influence of changes in the prices of farm products; the sources of loans; interest rates; and term and duration of loans are discussed. Indexes of the mortgage situation were prepared, and a table is given showing, by years 1910–31, the indexes of outstanding debt, acreage mortgaged, debt per acre, sale price of land, prices of farm products, number of land-purchase mortgages, and number of foreclosures and assignments. The defaults, 1921–31, and the debt by townships and individual farms are also discussed. The appendix includes tables showing, by years 1854–1931, the number of mortgages filed, released, and outstanding, the acreage covered by and the amount of first mortgages, the amount of junior mortgages, percentage of land mortgaged, debt per acre mortgaged, sale price per acre, number of foreclosures, index of prices of farm products, numbers of land-purchase transactions and land-purchase, renewal, and former-owner mortgages, and the distribution of outstanding debt by lenders. Some of the findings are as follows:

In the earlier years, private lenders and the county school fund were the principal sources of credit. The later years showed a declining percentage total to private investors and a rising proportion to insurance companies. From 1880 to 1900 local mortgage brokers selling to private investors were responsible for most of the assigned mortgages. Since 1920, State-wide loan companies selling to insurance companies have made practically all of the assignments. Assignments at no time constituted over 20 percent of the loans

executed. Lenders in the county and adjoining counties extended 50 percent of the credit throughout the period. Except prior to the Civil War, 5 years was the most common term specified for mortgage loans and the most common duration of loans. The total mortgage debt outstanding at the close of 1910 was \$5,900,000; 1920, \$22,900,000; and 1931, \$18,000,000. The percentages of land mortgaged in the respective years were 45, 58, and 59, and the average debt per acre \$37, \$111, and \$86. Of the farms with mortgage indebtedness in 1931, 31 percent were mortgaged for \$100 or more per acre, 32 percent between \$75 and \$99, and 37 percent for less than \$75. Only 4 percent had a debt of less than \$25 per acre.

Farm mortgage foreclosures in Minnesota, E. C. JOHNSON (*Minnesota Sta. Bul. 293 (1932), pp. 31, figs. 6*).—Tables are included and discussed showing the ratio of mortgage debt to value of land and buildings per mortgaged farm in Minnesota, 1910, 1920, 1925, and 1930, and the number of tracts and acres of land sold at sheriff's sale in individual counties in four sections of the State, by years 1920–31. From its organization in 1917 to December 31, 1930, the Federal Land Bank of St. Paul made 12,548 loans, totaling \$58,704,200, on Minnesota farms, of which 8,456 loans with a net principal of \$36,130,904 were outstanding on December 31, 1930. Tables show for these loans up to April 30, 1930, and for 433 of the farms on which foreclosures were made, the farms being grouped by districts of the State and according to whether the farms had been foreclosed on or whether the loans were in good standing, the number and amount of loans and foreclosures, assets and liabilities, and appraised value of land and buildings at the time the loans were made and at the time of foreclosure; percentage of loans made in different years; average mortgage debt per acre at the time of purchase and under the loans made; appraised value per acre and for house and other buildings; value of machinery and of livestock per 100 acres; average number of milk cows, other cattle, and hogs; size of farms; age of farmers; and causes of failure of farmers. The relations of land values in a number of Minnesota counties and of soil and productivity of land in Pope, Swift, Stearns, Kandiyohi, Norman, and Goodhue Counties to foreclosures and the bona fide sales of tracts of land and foreclosures on good and poor soils in representative townships of Pope and Swift Counties are analyzed.

Some of the findings were as follows: Failure of farmers have been more numerous in the northern than in the southern part of the State, although recently there have been many foreclosures in the southern part due largely to the decline in the price of hogs. On the whole, the indebtedness has been higher on the farms foreclosed on than on those with loans in good standing, due partly to higher purchase prices but perhaps more to the fact that the operators have had less ability, there being evidence that the farms foreclosed on were not so well organized or so well managed. Failures of farmers were relatively greater on the poorer lands. Unless there is a substantial increase in the prices of farm products, many farmers will ultimately fail unless creditors will make adjustments. To avoid a repetition of present conditions, credit policies must be changed. Appraisals for loans must be based on probable earnings of the land over a long period rather than on sale values at a particular time, risks in particular regions must be considered, payments on principal should be required during the life of the loan and additional payments encouraged in years of good returns, and careful attention must be given to the reasons for borrowing, and to guiding farmers with respect to the use of capital.

State and local tax revision in Colorado, G. S. KLEMMEDSON (*Colorado Sta. Bul. 398 (1932), pp. 124, figs. 7*).—This study was designed to serve as a basis

of equalization of taxes in Colorado. It was initiated in response to a consensus of opinion that farmers, ranchmen, and home and other real estate owners of the State were paying more than their share of the cost of government. The view was held that real estate should bear no more than 50 to 60 instead of 85 percent of the total tax burden.

Through reduction in assessments and failure to collect taxes, the State was forced into a serious situation. Collections dropped from an average of 97.8 percent in 1926 to 92.56 percent in 1930. The percentage of 1931 taxes collected in 1932 approximated 88, or a loss of 12 percent, which compares with a loss of 7.5 percent in 1930, when the taxes collected varied from 37.58 percent in Costilla County to 98.91 percent in Phillips County.

The conclusion was reached that the redistribution of the tax burden in Colorado as a relief to farmers, stockmen, small home owners, and real estate owners would help to improve general business conditions and restore prosperity to the State. The advantages and disadvantages of various forms of taxation are discussed in detail.

The University of Nebraska tax primer, edited by G. O. VIRTUE (*Nebraska Sta., 1932-1933, pp. [194]*).—This consists of Tax Circulars 1-12, constituting a series of 12 chapters written to supply information for Nebraska taxpayers as follows: (1) Public Expenditures, by G. O. Virtue (pp. 16), discusses public expenditures and taxation, the growth, classification, and control of expenditures, and why they have grown and remain high; (2) Public Revenues—Their Forms and Character, by Virtue (pp. 12), describes the tax and nontax revenues, equity in taxation, and the behavior of taxes; (3) The Revenue System—the Federal Revenues, by Virtue (pp. 11), describes the tax and nontax revenues for 1931, the evolution of the Federal system, and the present system; (4) The Revenue System—State Revenues, with Special Reference to Nebraska, by Virtue (pp. 22), deals with the tax and nontax revenues and the principal State and local taxes; (5) The General Property Tax, by R. H. Cole (pp. 15), discusses the general property tax and its administration, pointing out some of the defects and suggesting some reforms; (6) Taxation of Intangible Property, by Virtue (pp. 20), discusses the theory and practical operation of the intangible property tax in the several States of the United States, the Nebraska law, and why it has not fulfilled expectations, and suggests possible improvements in the law; (7) Exemptions, by Virtue (pp. 22), describes the nature and purpose of exemptions and the exemptions for public property and tangible and intangible private property; (8) The Sales Tax, by H. Hedges (pp. 11), discusses the kinds of sales taxes, such taxes in use, the economic and social effects, the administrative aspects, and the place of sales taxes in a tax system; (9) The Income Tax, by H. C. Filley (pp. 19), describes the kinds of income taxes, the income taxes of European countries, the Federal Government, and the several States, and discusses the costs of administration and the advantages and disadvantages of such taxes; (10) The Taxation of Corporations (pp. 15) includes an article by E. G. Callen on the franchise tax, one by E. B. Schmidt on the corporate excess tax, and one by Virtue on the banks; (11) The Relative Tax Burden, by R. J. W. Ely (pp. 21), discusses the problems of measurement of the tax burden, bases of computing tax ratios, and the burden of taxes in the United States, sections of the United States, and Nebraska on farm real estate, city real estate, railroads, telephone companies, commercial banks, and insurance companies; and (12) Tax Administration in Nebraska, by Callen (pp. 10), describes the machinery of assessment and its defects and makes suggestions for improvements.

Variation in local marketing procedure for grain, hay, livestock, and feed in northwestern Indiana, L. ROBERTSON and E. R. BONHAM (*Indiana*

Sta. Bul. 364 (1932), pp. 20, figs. 18).—Analysis is made of data obtained in 1929 from all agencies in the 12 northwestern counties of the State (a section in which there has been rapid industrial development in nearby cities) handling grain, hay, livestock, meats, or feeds. The data covered number, kind, and location of the marketing agencies; amount of each kind of produce handled from May 1928 to April 1929; proportion of products shipped out and sold locally; destination of products shipped out; and method of transportation, prices to farmers, etc.

The marketing procedure and problems varied greatly between the 9 agricultural regions of the section studied, the principal causes being differences in the prevailing types of farming and in location. The changes taking place in farm production and marketing have been more rapid in the area studied than in any other large section of the State.

Among the changes found were (1) a greater increase in the use of trucks with an accompanying decrease in the need for local marketing agencies and variation in prices of the same product in different sections; (2) smaller grain sales through local agencies; (3) smaller production of hay, smaller demand for timothy, and an increased outlet for legumes; (4) smaller marketing of hogs and beef cattle and less local killing of livestock; (5) an increase in dairy and poultry production and in nonfarming rural population; (6) increased demand for sacked feed, particularly in grain-deficit areas; (7) greater variation between depression and boom periods in the demand for farm products and the costs of marketing them than in sections farther out in the State; and (8) a tendency for permanent changes in market procedure to be more rapid than in sections less influenced by industrial growth.

The marketing of milk thru ice cream, M. C. BOND (*New York Cornell Sta. Bul. 546 (1932), pp. 88, figs. 26*).—The study deals with milk products used in ice cream plants in the State located outside New York City and with the daily sales of ice cream in Buffalo, N.Y. Practically all of the milk and skim milk and most of the condensed milk used was produced in New York State. About 80 percent of the cream came from New York and the rest came from Illinois. The powdered skim milk used came from New York (30 percent), the Central States (31 percent), and California (39 percent). Most of the butter used came from the Central States.

The manufacture of butter and cheese in New York State has declined greatly in recent years, while the production of ice cream has increased rapidly. Ice cream manufacture in the State has an important bearing upon the consumption of milk because ice cream is sold mainly during the months of surplus milk supply. This makes an outlet for a considerable supply of milk which would otherwise have to be used in other manufactured products which would bring lower returns.

The per capita consumption of ice cream in the United States, which was estimated at 1.4 gal. in 1910, had increased to 3 gal. in 1929. During the period 1920 to 1928, inclusive, ice cream production in the United States increased 29 percent, while in New York the increase was 90 percent, or about 3 times as rapid.

In 1925 and 1926, the average prices received by farmers for the whole-milk equivalent of all milk fat used in ice cream by the plants studied were about the same as the prices quoted for class 2 milk by the Dairymen's League Cooperative Association. The cost of milk products per gallon of ice cream decreased with the increase in the size of the plant. The lowest costs were found in plants using miscellaneous products including butter and powdered skim milk and the highest costs in plants purchasing ice cream mix exclusively.

Seasonal variations of ice cream sales in New York were slightly greater than for the United States. The efforts of manufacturers to increase winter sales resulted in only slight improvement in recent years. Sales are affected by temperatures. Changes above 40° F. have more effect than changes below 40°, and changes above 70° have the greatest effect on sales.

In addition to 68 tables in the text, 29 tables are presented in the appendix.

Cream grading on the four day delivery plan in Indiana, V. C. MANHAET (*Indiana Sta. Circ.* 193 (1932), pp. 20, figs. 5).—This circular describes the various phases of the operation of the 4-day delivery plan of cream grading and gives some data as to the results of its use in Indiana from 1927 to 1932, inclusive. The plan provides for four grades of cream as follows: Premium, sold at intervals of not more than four days and free from undesirable flavors and odors at the time of delivery; regular, sold at intervals of more than four days, and that sold at intervals of four days or less which contains undesirable flavors and odors but is not of such quality as to warrant placing it in the onion or rejected grade; onion cream, containing onion or garlic flavor; and rejected cream, which is rancid, moldy, dirty, oily, or otherwise unwholesome.

The percentage of cream marketed at intervals of four days or less increased from less than 20 percent in 1927 to 75.6 percent in 1932. Over a third of a million dollars in premiums was paid to farmers during the five years as a result of a 4-day grading plan. The plan has established a uniform system of buying on a grade basis with a tangible standard that cannot be misconstrued or misunderstood. It has improved the quality of cream delivered, thus making possible the manufacture of a good grade of butter and the payment of a higher price for butterfat. Investigations at the station showed that butter churned from premium cream scored about 1.25 points higher than that made from regular cream.

Operation and management of milk plants, C. E. CLEMENT (*U.S. Dept. Agr. Circ.* 260 (1933), pp. 51, figs. 8).—This circular, which supersedes the bulletin previously noted (*E.S.R.*, 49, p. 377), "gives basic information on the methods of operating milk plants which have proved to be satisfactory in practice, and discusses certain phases of management which are directly related to successful operation." The systems used in buying milk, receiving and pasteurizing milk, the operation of the pasteurizing and cooling equipment, bottling and capping, washing cans, milk-plant sanitation, bottle losses, goods returned, disposal of surplus milk, shrinkage in handling milk at plants, checking milk through the plant, and the number of men required to operate plants of different sizes and deliver milk are discussed.

Price spreads and restraint of United States wheat exports, A. E. TAYLOR ET AL. (*Wheat Studies, Food Res. Inst. [Stanford Univ.],* 9 (1932), No. 1, pp. [2]+22).—This is another of the series of studies of the world wheat situation in relation to national economy. The discussion comprises the European import trade, technic of wheat exporting, distressed wheat, pertinent statistics for 1931-32, why prices were above export parity, how commercial exports were possible, and concluding observations.

The United States, with an exportable surplus of record size, exported relatively little wheat and flour in 1931-32. Export business was sought by the Grain Stabilization Corporation, the private trade, and the cooperatives, but wheat prices here, though disastrously low, were too high to permit liberal commercial exports. Importing countries got their import supplies cheaper elsewhere.

The authors discuss the forces that are responsible for keeping United States wheat prices above the export basis in a period when our exportable surplus

is very large. The conditions permitting exports frequently to move out with Chicago futures above export parity with Liverpool prices are examined in considerable detail.

The authors conclude that in the absence of the Federal Farm Board support to the wheat market in 1929-31 other forces such as operated in 1931-32 would have limited the decline of domestic wheat prices, restrained exports, and enlarged the carry-over. The authors also explain that their analysis of the situation is tentative in character, and that no attempt has been made to weight the several factors involved.

Barter and scrip in the United States: Selected references (*U.S. Dept. Agr., Bur. Agr. Econ., Agr. Econ. Bibliog.* 40 (1933), pp. 43).—This is a mimeographed bibliography containing 252 selected references mainly on the use of barter and scrip in the United States including its use by chambers of commerce, municipalities, and self-help and emergency cooperative exchanges for the relief of unemployment. A few references on the history of barter and scrip are also included.

Crops and Markets, [February 1933] (*U.S. Dept. Agr., Crops and Markets*, 10 (1933), No. 2, pp. 33-80, figs. 3).—Included, besides the market reports for livestock and livestock products, dairy and poultry products, cold storage holdings, grain, hay, feed, seeds, fruits and vegetables, and cotton, and the summary of the price situation, are a summation of the agricultural outlook report for 1933 and the crop and livestock estimates for 1933, which include tables showing, by States, for 1931, 1932, and 1933 the number, farm value per head, and total farm value of horses and colts, mules and colts, milk cows and heifers, all cattle and calves, sheep and lambs, and swine on farms January 1; estimated prices of different farm products, January 15, 1932 and 1933; hog and corn ratios, by months, 1930-32; farm labor supply and demand, January 1, 1932 and 1933; average wages paid hired farm labor, January 1931, 1932, and 1933; estimated commercial acreage of specified truck crops, by years 1928-33; and the production of beans by commercial classes, by years 1929-32. Other tables show the monthly farm prices of different kinds of livestock and livestock products for periods of years, and other data as to farm prices, farm wages, hog-corn ratios, etc.

RURAL SOCIOLOGY

[Investigations in rural sociology of the Ohio Station] (*Ohio Sta. Bul.* 516 (1933), pp. 97, 98).—Findings are briefly noted as to the movement of open-country population in Ohio, by P. G. Beck, and on the growth cycle of the farm family, by C. E. Lively.

The Yankee community in rural New England, H. C. WOODWORTH (In *New England's Prospect*, 1933. *Amer. Geogr. Soc. Spec. Pub.* 16 (1933), pp. 178-188).—The author discusses the decadence and growth of rural New England communities and cites examples. In some communities agriculture has advanced, while in others it has waned. Forces influencing the growth of these communities discussed are psychological factors, differences of personnel within the community, family tradition as a tie to the soil, and farm abandonment.

The supreme effort is to keep the communities which remain in sound, healthy, and prosperous condition.

Recent immigrant stocks in New England agriculture, J. L. HYPES (In *New England's Prospect*, 1933. *Amer. Geogr. Soc. Spec. Pub.* 16 (1933), pp. 189-205, figs. 3).—The author found that an immigrant tide has flowed into

the farming communities as well as the mill towns of New England. More than a third of all the farm folk of New England are of foreign stock. This gives the section a higher proportion of foreign born in the rural population than any other section of the country except the Pacific coast.

Immigrants are further discussed from the viewpoints of types of farming, soil types, standards of labor, social conflict, the purchase of farms, social participation, socialization and education.

In conclusion, some 12 different types of needed social researches are listed.

Population trends in New York State, 1900 to 1930, W. A. ANDERSON (*New York Cornell Sta. Bul. 547 (1932), pp. 60, figs. 16*).—Changes occurring in number and proportions of the classes of population of New York State from 1900 to 1930 are pointed out. Census definitions are followed. During this period New York State population increased steadily and at a higher rate than that of the United States. Rural population decreased absolutely and relatively from 1900 to 1920, but increased from 1920 to 1930. Farm population decreased from 1900 to 1930, continuing the migration from farms begun about 1880. An increase in the rural-nonfarm population accounts for the increase in total rural population of the State. The suburbanization process was speeded up between 1920 and 1930 by automobiles, good roads, cheapness of rural lands, and advantages of living in open country.

Accompanying the decrease in farm population was a decrease in percentage of land in farms and number of farms. Much land, abandoned for farming purposes, was absorbed by suburban developments.

An appendix carries 25 tables in addition to those accompanying the text.

The qualitative nature of rural depopulation in Santuc Township, South Carolina, 1900–1930, W. GEE (*South Carolina Sta. Bul. 287 (1933), pp. 22, figs. 7*).—The author analyzes the rural migration of his native township for the period from 1900 to 1930. Prior to about 30 years ago, Union County, in which the area is located, was almost entirely agricultural but since has shared in considerable measure in the industrial development of the South.

The population of Santuc Township declined from 2,844, consisting of 695 whites and 2,149 negroes, in 1900 to 1,893, consisting of 571 whites and 1,322 negroes, in 1930.

By a process, somewhat intuitive and involving social and economic considerations with family tradition and community worth as essential elements, the white population of 1900 and again of 1930 was classified in upper, middle, and lower classes. What happened to each individual there in 1900 and where those who were there in 1930 but not there in 1900 came from were determined.

The upper class is predominantly the landowning class, with larger farms and families, on the average, in 1900 than in 1930. The middle class, to the extent of nearly half of them, own farms on the average somewhat more than half the size of the upper group and property assessed at considerably less than half the value. The lower class is largely a nonlandowning group and even under normal conditions would be classified as submarginal farmers.

Between 1900 and 1930 the number in the upper class declined from 250 to 160, or a percentage decline of 36; the middle class, on the contrary, increased from 314 to 361, or a percentage increase of 15; and the lower class declined from 131 to 50, or 61.8 percent. The author found in 1930 a depletion of the original stock in the upper class amounting to 50.8 percent, in the middle class 49.4 percent, and in the lower class 80.9 percent.

Of the severe depletion in the upper class, a considerable portion was occasioned by migration to cities, adjacent and distant. The loss must undeniably lower the levels of life in the rural section affected, although the

increase in the middle class, through immigration into the area, may eventually repair the loss. Industrial development in the Piedmont, of which Union County is a part, has drawn most heavily upon the lower class. The negro population of the township, which in 1900 amounted to nearly 76 percent of the population, had been reduced by 1930 to approximately 70 percent by cityward migrations. The number of negroes had been reduced from 2,149 in 1900 to 1,322 in 1930.

The conclusions are reached that while the township has suffered severely in both the absolute and proportionate loss of its best people, it has been compensated by negro emigration and white accretions to the middle and upper classes which tend to preserve and continue wholesome functioning of its population.

A reclassification of urban-rural population, T. J. WOOFER, JR., and E. WEBB (*Social Forces*, 11 (1933), No. 3, pp. 348-351, fig. 1).—The usual and the new classifications of the United States census are compared.

Farm trade centers in Louisiana, 1901 to 1931, T. L. SMITH (*Louisiana Stat. Bul.* 234 (1933), pp. 56 figs. 3).—Comparisons between 1901 and 1931 disclose fundamental changes under way in the social organization of the State. An increasing proportion of social activities is being organized around the larger trade centers. Small trade centers are losing in importance. Some are developing into larger centers, while others are being smothered out. However, small trade centers that supplement or complement larger centers are maintaining themselves.

The changes noted are widening the area of social contacts and reducing the social differences found to exist among the various community groups. A tendency toward division of labor between trade centers of different sizes was found.

The process of urbanization and industrialization is under way, and being less advanced than in other sections of the United States will continue for some time. Changes in the rice-farming area are more pronounced than in other parts of the State.

A decrease of familism was indicated. Contacts with the kinship group will become less and with other groups more frequent. Local ties will be weakened and those with special interest groups strengthened.

AGRICULTURAL AND HOME ECONOMICS EDUCATION

Producing farm livestock, J. L. EDMONDS, W. E. CARROLL, W. G. KAMMLADE, W. B. NEVENS, and R. R. SNAPP (*New York: John Wiley & Sons; London: Chapman & Hall*, 1932, pp. XIII+439, pl. 1, figs. 111).—This textbook presents the subject matter on the operative basis, i.e., in the form of the actual procedures, step by step, as taken up in practical livestock production. The several chapters deal with the establishing and organizing of dairy cattle, beef cattle, horse, sheep, and swine enterprises, the feeding and management of each kind of livestock, and marketing, improving, and exhibiting livestock.

Each chapter is followed by questions for farm or community studies and a list of selected references.

Organization and teaching procedure to be followed in evening agricultural schools on the marketing of poultry products (*Fed. Bd. Vocat. Ed. Monog.* 17 (1932), pp. III+40).—This publication was prepared by J. H. Pearson in cooperation with J. J. Scanlan of the Federal Farm Board. Analysis of the job of marketing poultry products is made, showing the decisions to be made, factors to be considered, and information needed to apply factors, and suggestions are included on teaching procedure for each factor.

Suggestions for studies and research in home-economics education (*Fed. Bd. Vocat. Ed. Bul. 166* (1932), pp. XI+77).—This bulletin, prepared by B. I. Coon in collaboration with C. M. Brown and R. M. Friant, outlines projects needing investigation and some basic considerations in relation to each. The possibilities in research and in home economics education, the factors to be considered in such research, and the responsibilities of institutions in giving training in such research are discussed. A partial outline of the fields of investigation and research is presented and discussed, and suggestions are made for its use.

A bibliography including references on educational research and studies and research in home economics education and abstracts of theses in home economics education completed during the year 1930-31 are given.

The teaching of science related to the home, E. P. AMIDON and H. B. MCKIBBEN (*Fed. Bd. Vocat. Ed. Bul. 158* (1931), pp. VII+127, figs. 12).—This bulletin presents suggestions for content and method in related science instruction in the vocational program in home economics. It discusses the need for science training and the problems involved in training teachers and including science in a vocational program in home making, work done and progress made in related science teaching in the vocational home-making departments, the objectives for a course in science related to the home, and the factors influencing selection of content and the sequence. Suggestions are made for methods of teaching and reference material and experiments, for the evaluation of results of teaching, and for the use and storage of equipment and supplies.

Appendixes include plans for including related science in the vocational home-making programs, extracts from a previous publication of the Board on Suggestions for Content and Methods for a Course in Science Related to the Home, a list of studies made and materials recently issued by States on the teaching of science related to the home, and an illustrative teaching plan for the development of a specific ability.

Workers in subjects pertaining to agriculture in State agricultural colleges and experiment stations, 1932-1933, M. A. AGNEW (*U.S. Dept. Agr., Misc. Pub. 154* (1933), pp. IV+133).—This is the usual annual list (*E.S.R.*, 67, p. 85) showing the workers in agriculture and home economics in the State and territorial colleges and stations, by departments, and other data.

FOODS—HUMAN NUTRITION

Practical physiological chemistry, P. B. HAWK and O. BERGEIM (*Philadelphia: P. Blakiston's Son & Co., 1931, 10. ed., rewritten, pp. XVIII+929, pls. 8, figs. 280*).—The tenth edition of this well-known volume (*E.S.R.*, 57, p. 291) marks the twenty-fifth anniversary of the first edition.

Nutrition laboratory, F. G. BENEDICT (*Carnegie Inst. Wash. Yearbooks*, 29 (1929-30), pp. 183-196; 30 (1930-31), pp. 223-238; 31 (1931-32), pp. 173-182).—The pages noted cover the annual progress reports since 1928-29 (*E.S.R.*, 63, p. 288). Most of the studies have been noted from other sources.

Nutritive value of cranberries, C. R. FELLERS (*Amer. Jour. Pub. Health*, 23 (1933), No. 1, pp. 13-18).—This report summarizes data, some of which have been noted from progress reports from the Massachusetts Experiment Station (*E.S.R.*, 67, p. 473), on the proximate composition of cranberries, the effect of ingestion of cranberries on the content of hippuric acid in the urine and the blood plasma alkali reserve, and the nutritive properties of cranberry sauce (method of preparation not stated).

The benzoic acid content of fresh cranberries was found to vary from 0.085 to 0.095 percent and that of quinic acid from 0.6 to 0.9 percent. The conju-

gation of these acids produces urinary acidity in proportion to the quantity of cranberries ingested, but servings of 5 oz. or less of cranberry sauce produced little change in either the pH or hippuric acid value of the urine. The alkali reserve of the blood showed no decrease until more than 5 oz. of cranberry sauce had been eaten, but larger amounts brought about a considerable decrease in alkalinity.

Data are also reported on the vitamin C content of different varieties of cranberries and of cranberry products. From 3 to 4 g of fresh cranberries sufficed to maintain normal growth and afford complete protection against scurvy in 300-g guinea pigs. The vitamin C content was not affected by freezing and subsequent storage at 0° F. for 9 months and only slightly affected by storage at 40° for 3 months. Alternate freezing and thawing proved very destructive. Fresh cranberry juice was quite as potent as the original fruit, but juice bottled by present commercial methods was practically devoid of vitamin C. Whole fruit sauce contained approximately 80 percent and strained sauce less than 10 percent of the original vitamin C content. Evaporated whole cranberries were devoid of vitamin C, but a quick-dried powder retained over 50 percent.

Vitamins B and D could not be detected, and vitamin G was present in traces only. Vitamin A was present in small but measurable quantity, 1.2 units per gram.

[**Fruit products**] (*California Sta. Rpt. 1932, pp. 29, 30*).—This progress report (E.S.R., 67, p. 622) deals briefly with tests of various canned and dried fruits for maintaining the alkaline reserves in the body, comparisons of quick freezing and slow freezing methods for the preservation of fruits and vegetables, chemical changes in fruits and methods of preserving orange juice in frozen storage, and methods for shipping fresh fruits overseas.

The sterilization of fruit juice with heat developed by the resistance of the juice to the passage of an alternating electric current, L. J. PEET and L. E. SATER (*Iowa Sta. Rpt. 1932, p. 95*).—Observations are reported on the appearance and sterility after nine months' storage of tomato, grape, and apple juices sterilized in the apparatus described previously (E.S.R., 67, p. 493).

Studies in home canning methods (*Indiana Sta. Rpt. 1932, pp. 44, 45*).—This progress report (E.S.R., 67, p. 637) includes further data on the comparative rate of heat penetration in oven, waterless cooker, and water bath processing, using peaches as the test food, and observations on the keeping quality of tomatoes processed in the oven for varying lengths of time.

Foods of ancient Hawaiians, C. D. MILLER (*Mid-Pacific Mag., 44 (1932), No. 4, pp. 337-342, figs. 4*).—A popular article based upon the author's studies on the nutritive value of some of the more important foods known to have been included in the diet of early Hawaiians (E.S.R., 67, p. 473).

Nutrition for superior growth, I. N. KUGELMASS (*Arch. Ped., 49 (1932), No. 11, pp. 713-729*).—In the author's opinion, "lack of supervision of the nutritional status of growing children and adolescents has actually been conducive to retrograde results in comparison with their nutritional course in infancy. These failures in child nutrition are undoubtedly due to the fact that a typical American dietary nonconductive to growth and development is foisted upon children dining with adults." With this in mind, the nutritive requirements of children as contrasted with adults are discussed with respect to energy, carbohydrate, fat, minerals, and vitamins.

A study of the food habits and physical development of pre-school children over a two-year period with special reference to seasonal variations in growth, H. McKAY and M. B. PATTON (*Ohio Sta. Bul. 516 (1933), pp.*

91-94).—In this progress report, data obtained in a weighed dietary study by the individual method of a small group of children for periods of seven consecutive days each during January, March, June, and October are summarized and discussed with reference to seasonal differences.

White House Conference on Child Health and Protection: Sect. I, Medical Service.—Growth and development of the child: Part III, Nutrition (*New York and London: Century Co., 1932, pp. XX+532, figs. 14*).—Following the general introduction by K. D. Blackfan, which appears in each of the four volumes comprising the complete report of the committee on growth and development of the White House Conference on Child Health and Protection, this volume consists of brief sections, most of which are followed by lists of literature references, on present-day knowledge concerning the following topics: Optimal growth and nutrition; appraisal of the national food supply; appraisal of food analysis; the relation of the amino acids to nutrition and growth; the protein requirements of infants and children; the metabolism of the sugars; the requirements of infants and children for carbohydrate; the phospholipids and sterols; fat as a constituent of the diet; vitamin A; the vitamin B complex; vitamin C; vitamin D; vitamin E; the pathology of vitamin deficiencies; minerals—common elements; iron in nutrition; iodine in nutrition; the significance in nutrition of physiologically rare elements; water; factors governing the energy requirements of children; the energy requirements of children in infancy; the energy requirements of children after infancy; human milk and artificial feeding; growth and health in relation to nutrition; the choice of foods; dietary adaptations for geographic and racial factors; the effect of cooking and preserving processes on the nutritive value of food; coffee, tea, and cocoa for children; feeding habits in children; and psychological factors in nutrition.

Continuation and extension of work on vegetable proteins, L. B. MENDEL and H. B. VICKERY (*Carnegie Inst. Wash. Yearbooks, 29 (1929-30), pp. 380-389; 30 (1930-31), pp. 430-441; 31 (1931-32), pp. 314-321*).—The pages noted cover the annual progress reports (E.S.R., 63, p. 392) for the years 1929-30, 1930-31, and 1931-32. Most of the studies have been noted previously from other sources.

The protein requirements of the albino mouse, F. C. BING, W. L. ADAMS, and R. O. BOWMAN (*Jour. Nutrition, 5 (1932), No. 6, pp. 571-579, fig. 1*).—Studies are reported leading to the conclusion that, "contrary to what has been believed, the protein requirements of the mouse are certainly fulfilled by diets containing 15.6 percent casein, and probably somewhat less would also be satisfactory. These are about the same as the requirements of the rat, the differences due to metabolic rates becoming apparent when the gain in weight per gram of ingested protein is measured."

The relation of the dicarboxylic amino acids to nutrition, R. R. ST. JULIAN and W. C. ROSE (*Jour. Biol. Chem., 98 (1932), No. 2, pp. 439-443, fig. 1*).—In this reinvestigation of the relation of the dicarboxylic amino acids to growth (E.S.R., 58, p. 892), the removal of aspartic, glutamic, and hydroxyglutamic acids from hydrolyzed casein was found to have no effect upon the nutritive value of the resulting material. This is thought to indicate that the dicarboxylic amino acids are not indispensable dietary components.

Proline and hydroxyproline in nutrition, R. R. ST. JULIAN and W. C. ROSE (*Jour. Biol. Chem., 98 (1932), No. 2, pp. 445-455, figs. 3*).—In this attempt to answer the disputed question as to the indispensability of the amino acids proline and hydroxyproline in nutrition, the dry mixture of amino acids obtained by acid hydrolysis of casein, lactalbumin, and edestin was subjected to 40 ex-

tractions each with absolute ethyl alcohol and then fed to rats at a 9 percent level (including suitable amino acid substances). The supplements were tryptophane and cystine for the extracted casein and lactalbumin, and tryptophane, cystine, and lysine for the extracted edestin.

Growth at moderately rapid rates resulted in each case and was not increased by the administration of 50 mg of proline daily. The supplementing effect of hydroxyproline was not tested.

The authors conclude that proline is a dispensable amino acid. In view of uncertainty as to the completeness of removal of hydroxyproline, no positive statement is made concerning its dispensability.

The possible interchangeability in nutrition of certain 5-carbon amino acids. R. R. ST. JULIAN and W. C. ROSE (*Jour. Biol. Chem.*, 98 (1932), No. 2, pp. 457-463, fig. 1).—In view of the evidence reported in the two papers noted above pointing to the dispensable nature of the glutamic acids, proline, and possibly hydroxyproline and previous findings from the same laboratory indicating the dispensable nature of arginine, the possibility that these amino acids might be interchangeable in the diet was tested by suitable feeding experiments.

Arginine, the dibasic amino acids, and the prolines were removed from hydrolyzed casein, and the remaining amino acids, supplemented with tryptophane, cystine, and histidine, were fed at an 11.5 percent level as the sole source of nitrogen except for that present in 100 mg of yeast daily in otherwise adequate diets. Although the rats receiving these food mixtures grew at only about half the normal rate, the incorporation of suitable quantities of arginine, aspartic and glutamic acids, and proline did not improve the growth rate.

"The above results appear to indicate that the 5-carbon amino acids, ornithine, glutamic acid, hydroxyglutamic acid, proline, and hydroxyproline, are not capable of playing an interchangeable role in nutrition. However, final judgment must await the results of feeding experiments involving the use of mixtures of highly purified amino acids known to be entirely devoid of the compounds in question."

The metabolism of cystine and methionine: The availability of methionine in supplementing a diet deficient in cystine. R. W. JACKSON and R. J. BLOCK (*Jour. Biol. Chem.*, 98 (1932), No. 2, pp. 465-477, figs. 4).—Evidence is presented leading to the conclusion that methionine, the sulfur-containing amino acid discovered by Mueller (*E.S.R.*, 51, p. 109), is capable of stimulating growth in white rats on a diet deficient in cystine. Various other amino acids, including serine and alanine, were ineffective. The restriction of the food intake to a constant amount throughout the experiment, as described in a previous paper (*E.S.R.*, 62, p. 790), did not prevent growth acceleration by the methionine.

Various interpretations of the supplemental effect of methionine are proposed and discussed, with the conclusion that "further study is necessary to permit a precise interpretation of the facts at hand."

Factors in food influencing hemoglobin regeneration.—II, Liver in comparison with whole wheat and prepared bran. M. S. ROSE and L. KUNG (*Jour. Biol. Chem.*, 98 (1932), No. 2, pp. 417-437, figs. 2).—In connection with the first study of the series (*E.S.R.*, 68, p. 412), the observation was made that the amount of hemoglobin regenerated in rats on feeding 1 g of beef liver daily was less than that from 1.5 g of whole wheat furnishing approximately the same amount of iron, 0.05 mg. To determine whether or not the apparently poorer utilization of the iron from the liver was due to storage in some form other than hemoglobin, young rats from mothers on a normal diet were fed

milk exclusively until their hemoglobin dropped below 7 g per 100 cc of blood and were then put on diets known to be adequate to restore hemoglobin to a normal level (16 g per 100 cc of blood) in 6 weeks. Four of the diets consisted of milk supplemented daily by (1) 6.5 g of whole wheat, (2) 1.8 g of prepared bran, (3) 1.6 g dried liver, and (4) 3.6 g prepared bran. The first two furnished 0.2 mg and the others 0.4 mg of iron daily. The fifth diet was a modified Osborne and Mendel diet furnishing 0.38 mg of iron daily. Normal hemoglobin levels were reached on diet 4 in 3 weeks and on the others in 5 or 6 weeks. Growth was greatest on the diet containing liver and the modified Osborne and Mendel diet, next on the whole wheat, and least on the bran.

At the end of the 6 weeks' feeding period the animals were all depleted by milk feeding and repeated bleeding from the heart until the hemoglobin was reduced to an average of about 6 g per 100 cc of blood, at which point the animals were all killed and their bodies analyzed for iron. From hemoglobin determinations at the beginning and end of the bleeding period, the extent of hemoglobin removal was determined.

"It was found that differences between sexes were marked, females per unit of weight yielding more hemoglobin than males, and thus indicating greater capacity for storage. Taking hemoglobin withdrawn from the animals on 0.2 mg of iron in the form of whole wheat as the basis for comparison, those on 1.8 g of bran grew less well and produced slightly less hemoglobin, those on 0.4 mg of iron as liver grew slightly better but produced no more hemoglobin. Animals on 0.4 mg of iron as bran produced slightly more than those on 0.2 g of whole wheat, indicating that 0.2 mg of iron is slightly below the optimum daily amount for the rat. Experience with other diets yielding more than the minimum requirement of iron in readily available form . . . indicates that iron furnished in amounts above this optimum for maintenance of normal hemoglobin is not held in reserve."

There was a striking constancy in the iron content of the bodies of the rats at the end of the bleeding period regardless of sex or diet. The content of iron in 78 bodies averaged 0.0021 ± 0.00003 percent.

The effects of yeast ingestion on the composition of the urine and feces, H. B. PIERCE (*Jour. Biol. Chem.*, 98 (1932), No. 2, pp. 509-535).—This extensive investigation, in which the author had the assistance of D. D. Posson, V. du Vigneaud, C. A. Morrison, Z. du Vigneaud, and M. S. Pierce, had two objectives: (1) To determine the changes in the chemical composition of the urine and feces as a result of the ingestion of bakers' yeast and the relation of these changes to intestinal putrefaction, and (2) to determine whether yeast used under controlled conditions has a laxative action, this being interpreted as "an easier or more complete evacuation of the lower bowel." The subjects were four healthy adults who were engaged in laboratory work during the course of the experiment. Three different diets were used, one of them for a preliminary study on a single subject and the other two for the main experiment with all four subjects. Of these, diet 2 contained somewhat more protein and diet 3 more carbohydrate than was usually present in the dietary of the subjects. The yeast was taken raw by all subjects, 1 or 2 cakes being taken before each meal. The conclusions drawn concerning the laxative action of the yeast were as follows:

"Judged by the number of stools, by the weight and bulk of the stools, and by the ease of evacuation, live yeast had a laxative effect. The results were more marked in the first yeast period than in the second. The effect extended over into the following control period frequently. The action was more marked

on a carbohydrate-rich than on a protein-rich diet. The moisture content of the feces as a general rule decreased during yeast periods, only constipated subjects showing an increase in the percentage of water."

There was a greater elimination of phenol, indican, and indole during the yeast than the control periods. Several possible explanations of this are suggested. The phenol content of the urine suggested that yeast caused diminution in putrefaction. The increases in indican and indole were not as great as would be expected if the yeast tryptophane had been subjected to the same degree of putrefaction as that of the protein of the control diet. The elimination of inorganic sulfates decreased and of etheral sulfates increased during the yeast periods. The latter was not materially influenced by the type of diet, suggesting that it was of endogenous origin.

The titratable acidity of the urine fell during the yeast periods. There was a greater elimination of urinary ammonia in the majority of the average trials and a marked increase in fecal ammonia in every trial. It is thought that the extra ammonia formed during the yeast periods was for the purpose of neutralizing extra acid and conserving the fixed base in the body. The volatile acid excretion in the feces increased during the yeast periods, particularly on the carbohydrate diet. All of the subjects were in positive nitrogen balance during the yeast periods, and in some of the trials the nitrogen retained was more than equivalent to that contained in the yeast. The results were variable in the uric acid excretion, which showed no relationship to urinary nitrogen. This is thought to indicate that the individual subjects possessed varying capacities to metabolize nucleoproteins. "From the results obtained, it does not seem probable that yeast, at least in the quantities consumed in this investigation, would cause an increase in uric acid production sufficiently great to exert a harmful effect on the organism."

The effect of the calcium-phosphorus relationship on growth, calcification, and blood composition of the rat. R. M. BETHKE, C. H. KICK, and W. WILDER (*Jour. Biol. Chem.*, 98 (1932), No. 2, pp. 389-403).—In this investigation at the Ohio Experiment Station, data were obtained on the growth, ash content of the femurs, calcification of the ulnae and radii, and phosphorus and calcium content of the blood serum of rats on diets varying in their absolute and relative content of calcium and phosphorus with and without vitamin D.

"The data in general show conclusively that in the absence of vitamin D the proportion of calcium to phosphorus in the ration, within certain limits, exerts a marked effect upon growth, bone formation, and the percentages of these elements in the blood. Although the concentration or the levels at which calcium and phosphorus were present in the ration had some beneficial effect on growth and bone formation, this effect was not as great as that exerted by the actual proportion between the elements. The inclusion of vitamin D not only tended to stabilize the calcium and inorganic phosphorus concentrations in the blood serum, but made a greater percentage of these elements available for such biological phenomena as calcification and growth. Evidence is also presented showing that the wider the Ca:P ratio the greater are the requirements for vitamin D. With the same amount of irradiated ergosterol, a ration possessing a Ca:P ratio of 5 produced bones from 6 to 7 percent lower in ash than did a similar ration with a Ca:P ratio falling between 2 and 0.5."

Attention is called to the importance of taking these facts into consideration in attempts to evaluate foods or rations for their calcifying properties and for their content of vitamin D. It is emphasized that a distinction should be made between calcification studies to determine the "over-all" effect (the combined effect of inorganic elements and vitamin D) of a foodstuff and its inherent vitamin D potency. "The actual vitamin D content of a food can

only be determined when other inherent factors, such as calcium and phosphorus, are corrected for."

Bibliography on heavy metals in food and biological material.—I, Cooper, compiled by T. H. POPE (*Analyst*, 57 (1932), No. 680, pp. 709-714).—An extensive list of annotated references from 1921 to date.

The heat production of unusually large rats during prolonged fasting. F. G. BENEDICT, K. HORST, and L. B. MENDEL (*Jour. Nutrition*, 5 (1932), No. 6, pp. 581-597).—In this extension of the investigation noted previously (E.S.R., 65, p. 98) to metabolism determinations during prolonged fasting on two unusually large rats (initial weights at the beginning of the experiments 822 and 730 g) and to basal metabolism measurements on a number of other full grown rats, some medium in size (307 to 396 g) and others large (407 to 562 g), it was found that the larger the rat the lower the basal metabolism per unit of weight and unit of surface area. "With one of the large rats minimum values of 377 and 381 calories per square meter of body surface per 24 hours were recorded on the twenty-ninth and forty-third days of fasting. This is probably the lowest heat production that has been noted with warm-blooded animals having a rectal temperature of essentially 37° C."

Physiological functions of vitamins. R. R. WILLIAMS and W. H. EDDY (*Carnegie Inst. Wash. Yearbooks*, 29 (1929-30), pp. 389-395; 30 (1930-31), pp. 441-447; 31 (1931-32), pp. 321-325).—The pages noted cover three annual progress reports on the investigation noted previously (E.S.R., 63, p. 292). Progress during 1929-30 has been noted essentially in papers by Williams, Waterman, and Gurin (E.S.R., 62, p. 113) and Eddy, Gurin, and Keresztesy (E.S.R., 64, p. 294) for the B vitamins, and Dalldorf and Zall (E.S.R., 63, p. 696) for vitamin C.

The progress report for 1930-31 deals with further attempts to isolate vitamin B (B₁) in quantity from rice polishings, a reexamination of the effect of food consumption upon the requirement for vitamin B, a comparison of the relationship of the pathology of rat dermatitis to that of human pellagra (E.S.R., 66, p. 692), a study of the pathology of scurvy, as noted in a paper by Dalldorf (E.S.R., 66, p. 795), vitamin A technic, and the solarization of ultraviolet transmitting glass.

The report for 1931-32 is concerned with further attempts at isolating vitamin B from rice polishings and includes a brief summary of the results obtained by other investigators and a discussion of the difficulties involved in large scale extraction.

[Vitamin studies at the Iowa Station] (*Iowa Sta. Rpt. 1932*, pp. 48, 92-95).—Progress reports (E.S.R., 67, p. 473) are given on investigations dealing with the intestinal iron reduction test for vitamin D and attempts to synthesize vitamin D, by L. Yoder; improvements in the basal ration for vitamin A determinations and a statistical study of growth records of the stock colony of rats over a period of three years, by P. M. Nelson and P. P. Swanson; the effect of storage of canned tomatoes for one, two, and three years on the content of vitamin A, by Nelson, Swanson, and E. S. Haber; and the effect of varying fertilizer treatments on the vitamin A content of sweetpotatoes of the Prolific variety, by Swanson, Nelson, and Haber.

Recent knowledge of vitamins A and D. D. L. TABERN (*Clin. Med. and Surg.*, 40 (1933), No. 1, pp. 9-12).—In this review of recent literature on vitamin D, particular emphasis is given to discrepancies in the effectiveness for infants (and also children) of doses of liver oils and of viosterol of the same number of rat units and to the necessity for caution "in proposing and utilizing concentrates and artificially prepared vitamin A and D solutions other than

viosterol until there is ample evidence of their clinical efficiency in the human organism."

The selected references on vitamin A deal chiefly with the treatment of various pathological conditions involving mucous membranes with vitamin A and vitamin A reserves in the body.

The effects of vitamins A and D on antibody production and resistance to infection, M. R. GREENE (*Amer. Jour. Hyg.*, 17 (1933), No. 1, pp. 60-101).—This contribution to the extensive and conflicting literature on the subject reports an investigation of the "related cellular and humoral changes in the blood and other body fluids, with consequent variations in the kinds and amounts of natural and immune antibodies" as possible predisposing factors to infection in vitamin deficiency. Rabbits were selected as the experimental animal, and deficiencies in vitamins A and D were studied with respect to their effect on tissue antigen (sheep and ox red corpuscles) and a bacterial antigen (*Bacillus typhosus*). Physiological changes in the vitamin deficient animals, changes in the bacteriology of the upper respiratory tract, and the resistance to infection with various organisms were also studied.

Contrary to previous findings of Werkman (E.S.R., 49, p. 279), a marked lack of response to immunization with sheep red blood corpuscles was observed in the vitamin A-deficient animals. This was not true of the vitamin D-deficient animals. No change in complement or in erythrocyte counts occurred in either deficiency. These findings are in harmony with evidence reported by other investigators.

Leucocytosis was observed in the A-deficient but not in the D-deficient animals. These results are in harmony for vitamin A with observations of Turner and Loew (E.S.R., 66, p. 196) on rats and with those of Sure et al. (E.S.R., 66, p. 198) for vitamin D, but contrary to the latter for vitamin A.

A lowering of body temperature in the vitamin A-deficient animals occurred only shortly before death, and not progressively during the depletion period as noted by Werkman. Both the vitamin A- and vitamin D-deficient animals appeared to have a definitely increased susceptibility to inoculation with pneumococcus and *Bacterium leptisepticum*.

Vitamins aid reduction of lost time in industry, A. D. HOLMES, M. G. PIGOTT, W. A. SAWYER, and L. COMSTOCK (*Indus. and Engin. Chem.*, 24 (1932), No. 9, pp. 1058-1060).—In this attempt to determine if the use of cod-liver oil as a supplement to the usual home diet would be of economic value to an industry through raising the resistance of the workers to disabling colds and similar infections, 185 employees (115 women and 70 men) in a large industrial organization were given one tablespoonful of cod-liver oil daily during the morning or afternoon rest period for a 4-month period from December to March, inclusive, while a group of 128 (88 women and 40 men) served as controls. Records were kept of illnesses and absence from work in both groups. The ages of the subjects ranged from below 20 to above 45 years, with 87.6 percent between 21 and 45 years. The types of work represented were office 34, light machine work 27.6, and heavier machine work 38.4 percent.

During the period under observation, 55.1 percent of the cod-liver oil group and 32.8 percent of the control group developed no colds and 51.9 percent of the first and 40.6 of the second group lost no time from work. The average hours of absence for the two groups were 12.8 and 25.1, respectively, as compared with 20.4 and 17.4 for the same subjects during the corresponding period of the previous year when the diets were not supplemented.

"From these data it would appear that feeding a vitamin-rich material as a supplement to the home dietary materially reduced the economic loss to employer and employee occasioned by lost time of industrial workers."

Results of supplementing the dietary of substandard workers with cod liver oil and milk, A. D. HOLMES, M. G. PIGOTT, W. A. SAWYER, and L. COMSTOCK (*Jour. Indus. Hyg.*, 14 (1932), No. 6, pp. 207-215, figs. 6).—This investigation differs from the one noted above in that the subjects were a smaller group of underweight young women. The supplements to the diet included 1 pt. of milk daily in addition to the cod-liver oil, and the period of supplementary feeding was one year in the case of 45, and two years in the case of 18 subjects. The observations, which were taken during the 5-month period of December to May, inclusive, included changes in weight, absences due to illness, efficiency ratings, and menstrual irregularities.

In the one-year test the addition of the supplements was followed in the majority of instances by an increase in body weight averaging 2.6 lb., a decrease in absence from employment, and an increase in efficiency. There was also some indication of an improvement in menstrual irregularities.

In the two-year test all but 3 of the 18 women gained in weight each year, averaging 4.5 lb. during the first year and 1 lb. during the second year. The average hours of absence for December to May totaled 105.3 for the year previous to the test, 68.4 for the first year, and 40.8 for the second year, representing a total reduction of 61 percent. The average efficiencies for the group during the same three years were 77.8, 78.8, and 80.1 percent, respectively.

The authors conclude that "the addition of cod-liver oil and milk to the usual home diet contributes very materially to the well-being and efficiency of underweight young women dependent upon their ability to work for a livelihood."

[Vitamin A studies in Indiana] (*Indiana Sta. Rpt.* 1932, p. 57).—Loss of vitamin A is noted in exposure of butter to ultraviolet light, in the treatment of cod-liver oil and of butterfat with charcoal, and in the preparation of commercial butter coloring matter from annatto seed.

Vitamin A in body and liver oils of some Philippine fishes, D. M. BROSSEL, and N. J. SISON (*Univ. Philippines, Nat. and Appl. Sci. Bul.*, 2 (1932), No. 1, pp. 7-13, pls. 5).—Antimony trichloride color tests for vitamin A are reported for the body and liver oils of 44 varieties of Philippine fish and the body oils of 7 locally known types of shrimp and 2 of crabs. As only qualitative estimates in terms of deep, medium, and pale blue are given, the results reported are not of great significance. It is of interest, however, that the body oils of the shrimps gave a paler color than those of fish, and those of crabs a still paler color. As was to be expected, the fish liver oils gave a much deeper color than the body oils.

Discussion on vitamin-A and the carotenoids (In *Chemistry at the Centenary* (1931) *Meeting of the British Association for the Advancement of Science*. Cambridge: W. Hefter & Sons, 1932, pp. 79-126, pl. 1, figs. 3).—This symposium includes an introduction by F. G. Hopkins (pp. 79-81), followed by reports of recent research on the subject as follows: Carotenoids and Vitamin-A, by P. Karrer (pp. 82-91); Biochemical Experiments with Carotenes and Vitamin-A, by H. von Euler (pp. 92-101); Spectrographic Investigations in Connexion with Vitamin-A, by R. A. Morton and I. M. Hellbron (pp. 102-107); Preparation of Isomeric Carotenes and Their Biological Effects, by R. Kuhn (pp. 108-115); Steps in the Concentration of Vitamin-A, by T. Moore (pp. 116-122); and Contribution to Discussion on Vitamin-A, by J. C. Drummond (pp. 123-126). Many references to the original literature are included.

Discussion on the chemistry of vitamin-B and related problems (In *Chemistry at the Centenary* (1931) *Meeting of the British Association for the Advancement of Science*. Cambridge: W. Hefter & Sons, 1932, pp. 127-162).—Included in this symposium are the following papers: The Isolation of

Vitamin-B₁, by B. C. P. Jansen (pp. 127-130); The Vitamin-B Complex, by R. A. Peters et al. (pp. 131-146); Contribution to Discussion on Vitamin-B, by J. C. Drummond (pp. 147, 148); Crystalline Preparations of Vitamin-D Obtained by Distillation, by R. K. Cullow (pp. 149-154); Ergosterol, by A. Windaus (p. 155); Isolation of a Crystalline Antirachitic Reaction Product from Irradiated Ergosterol, by E. H. Reerink and A. van Wijk (pp. 156-158); The Preparation and Properties of Some Ergosterol Ethers, by I. M. Heilbron and J. C. E. Simpson (pp. 159, 160); and Conclusion, by R. Robinson (pp. 161, 162).

Carotene and vitamin A [trans. title], H. VON EULER (*Bul. Soc. Chim. Biol.*, 14 (1932), No. 6, pp. 838-860, fig. 1).—This lecture deals particularly with the extensive researches of the author and his associates on the relationship of carotene to vitamin A. A list of 91 references to the literature is appended.

Carotin in mango fruit (*Mangifera indica* Lin.), R. YAMAMOTO, Y. OSIMA, and T. GOMA (*Inst. Phys. and Chem. Res. [Tokyo] Sci. Papers*, 19 (1932), No. 386, pp. 122-126).—From 38 kg of the fresh pulp of the mango, 0.06 g of a mixture of α - and β -carotene, melting point 179° C., was isolated, together with a small amount of α -carotene, melting point 174°. Daily doses of 0.05 mg of the fraction melting at 179° proved sufficient to cure albino rats suffering from vitamin A deficiency. The distribution of carotinoids in 1 kg of the pulp of the mango was estimated to be carotene 20.41, free xanthophyll 2.7, and ester xanthophyll 13.58 mg.

Intensive vitamin therapy in measles, J. B. ELLISON (*Brit. Med. Jour.*, No. 3745 (1932), pp. 708-711).—The accumulated evidence of damage to epithelial cells as a result of vitamin A deficiency and the well-known damage to such cells in measles, often resulting in acute interstitial pneumonia or in various affections of the skin, ears, and mastoid cells, led to an investigation of the therapeutic effects of liberal dosages of a cod-liver oil concentrate in 300 cases of measles in children under 5 years of age as compared with a well-matched group of the same number receiving no supplement.

In all there were 26 deaths in the control group and 11 in the group receiving the concentrate, or 8.7 and 3.7 percent, respectively. In a previous epidemic involving a total of 4,978 cases the death rate had been 8.1 percent. Nearly all of the deaths in both groups of the present study were from pneumonia. There was no evidence of protection against infections of the middle ear or against skin complications.

"Although the evidence submitted in this experiment scarcely amounts to a demonstration of the value of intensive vitamin therapy in measles, it is difficult to resist the conclusion that some protective effect was obtained in the treated cases which tended to limit the severity of the pulmonary complications. The use of a concentrate rich in vitamin A as a prophylactic against secondary infections in a population of young children known to have been exposed to measles might well repay further study."

On the cause of infections in cases of vitamin-A deficiency, P. ARONS and M. P. J. VAN DER RIJST (*Arch. Néerland. Physiol. Homme et Anim.*, 17 (1932), No. 4, pp. 578-613, figs. 5).—Further evidence that "the infections resulting from a deficiency found in rats deprived of vitamin A probably are not the result of diminished powers of resistance, but of local changes caused by keratinized epithelium and atrophy of the glands" is given in the report of the gross and microscopic examination of various organs of a large number of rats on several test diets, but all deficient in vitamin A. Keratinization without infection was often found but never infection without keratinization. The order in which abscesses occurred in the several organs was roughly the same in all instances, starting with abscesses at the base of the tongue and followed in

later stages by abscesses in the seminal vesicles, salivary glands, and renal pelvis.

Studies on the vitamin-B complex, C. H. HUNT, R. M. BETHKE, and W. WILDER (*Ohio Sta. Bul.* 516 (1933), p. 90).—A continuation of earlier studies (E.S.R., 67, p. 88).

Effect of heat at varying concentrations of hydrogen ion on vitamin B (B_1) in protein-free milk, N. HALLIDAY (*Jour. Biol. Chem.*, 98 (1932), No. 2, pp. 707-717, figs. 2; *abs. in Michigan Sta. Quart. Bul.*, 15 (1933), No. 3, p. 207).—In this investigation at the Michigan Experiment Station, the author, with the assistance of V. E. Hiller, has employed the same materials and in general the same technic as in the earlier study of vitamin G (E.S.R., 67, p. 359) to determine the stability of vitamin B (B_1) to heat and alkalinity. The first series of experiments, noted previously (E.S.R., 68, p. 279), led to the conclusion that in testing for vitamin B in rather highly purified materials some factor or factors apparently present in whole wheat (probably the vitamin B_2 of Reader) must be added to the Sherman-Chase basal diet. Consequently another series of tests was run in which all of the animals received in addition to the skim milk powder or liquid supplement being tested 0.2 g daily of whole wheat.

The data obtained showed that the extraction of vitamin B from the skim milk powder into the protein-free milk was complete, and that in general the stability of the vitamin under the conditions of the experiment was similar to that of vitamin G. "Heating 1 hour caused about 25 percent loss at pH 4.3, 30 percent at pH 7, and 70 to 80 percent at pH 10. Heating 4 hours caused 30 to 40 percent loss at pH 4.3, 40 percent at pH 7, and almost complete destruction at pH 10. Holding the solution 1 week in the cold caused practically no loss at pH 4.3 or pH 7, but nearly complete loss at pH 10."

In discussing these findings with reference to the common belief that vitamin G is more stable to heat than vitamin B, the author states that "it may be possible that the use of the terms heat-labile and heat-stable may have to be discontinued." Attention is called to the probable multiple nature of vitamin G and the consequent difficulty in attempting to make any statement concerning its chemical nature.

The relation of the vitamin B complex to renal enlargement caused by cystine and protein in the diet of the rat, B. B. LONGWELL, R. M. HILL, and R. C. LEWIS (*Jour. Nutrition*, 5 (1932), No. 6, pp. 539-550).—The literature on the role of proteins and their derivatives in the etiology of kidney disease and on the possible relationship of vitamin B to protein metabolism is discussed, and data are reported on an investigation of the effects of high protein and cystine, with and without whole yeast extract, on the kidney structure of male rats.

Both cystine at 0.6 percent level and casein at a 40 percent level caused enlargement of the kidney when the yeast extract was not given as a dietary supplement. Graded doses of the yeast extract up to a certain point caused a progressively decreasing response on the part of the kidney to the administration of cystine or casein. The condition of the kidney is tentatively described as hypertrophy, since no evidence was obtained of degenerative lesions.

The effect of ultra-violet rays on the dermatitis preventing vitamin, A. G. HOGAN and L. R. RICHARDSON (*Missouri Sta. Res. Bul.* 178 (1932), pp. 18, figs. 3).—This publication includes a review of the literature on the differentiation of vitamins B and G, on attempts with varying success and conflicting results to produce dermatitis in rats on diets deficient in vitamin G, and on previous work in the field of the present investigation—the destruction of vitamin G by irradiation. The experimental work reported consisted in the

improvement of technic by means of which, in contrast to the irregular results obtained in a preliminary study (E.S.R., 60, p. 293), dermatitis was produced consistently in rats. Two essentials for consistent success were found to be rigid purification of the ration from the protective factor and irradiation of sufficient intensity to destroy all of the factor.

The preparation of the ration and the technic for irradiation are described in considerable detail, together with the symptoms of the dermatitis produced in all of the animals on the experimental diet. The development of the dermatitis follows a course similar in some respects to the descriptions from other laboratories but differing sharply in certain points. The lesions are limited to the feet, muzzle, eyes, and ears, and there is no loss of fur except in the affected areas. A preliminary histological examination of the lesions by J. W. Kennedy indicated that the dermatitis is of the type described by Findlay (E.S.R., 60, p. 493) and Thatcher, Sure, and Walker (E.S.R., 65, p. 495) rather than that described by Denton (E.S.R., 60, p. 793).

"The question has been raised as to whether the symptoms observed are due to a single or multiple deficiency, but it is impossible to decide that point at this time. No extended effort has been made as yet to determine whether the destruction of vitamin G is complete, or whether partial destruction of other factors occurred. As a matter of fact the designation of any one factor as G must be tentative until it becomes more certain that further differentiation cannot be accomplished. It is entirely possible that there are several types of dermatitis, each due to a different deficiency."

The stability of vitamin C and its relationship to the natural copper content in canned foods [trans. title], E. REMY (*Arch. Hyg. u. Bakt.*, 107 (1932), No. 3-4, pp. 139-154, pls. 2, figs. 9).—Proximate and mineral analyses and biological tests for vitamin C are reported for canned green beans, peas, spinach, apricots, and strawberries, together with determinations of H-ion concentration and reduction capacity for indophenol. The vitamin data are of little quantitative value inasmuch as no attempt was made to determine minimum protective doses, and corresponding values for raw materials were not given. The canned apricots showed no antiscorbutic potency. Values for the other foods were lower than the usually accepted figures for the same foods in the fresh state. The reduction potential values were roughly proportional to the vitamin C values, and this determination is considered of qualitative though not quantitative value. There was some evidence of an inverse relationship between the vitamin C values and copper content of the materials tested.

The role of activated milk in the anti-rickets campaign, A. F. HESS (*Amer. Jour. Pub. Health*, 22 (1932), No. 12, pp. 1215-1219).—This paper and the two noted below were read at a symposium on milks of special antirachitic value before the food and nutrition section of the American Public Health Association at its 1932 meeting.

Special emphasis is given to milk enriched with vitamin D by direct irradiation according to the method developed by Supplee et al. (E.S.R., 67, p. 489) and to the discrepancy between the clinical value of certain antirachitic agents and the laboratory measurements of their vitamin D content. Milk activated by irradiation is considered to have the advantage "not only of providing an automatic method of preventing rickets and of supplying this essential factor in a medium rich in phosphorus and calcium, but, as has been shown, it accomplishes this end by means of an exceptionally small amount of the antirachitic factor. In view of these important advantages I do not hesitate to recommend the general use of such milk for infants and children, especially in large communities."

Protective value for infants of various types of vitamin D fortified milk: A preliminary report, J. MCK. MITCHELL, J. EIMAN, D. V. WHIPPLE, and J. STOKES, JR. (*Amer. Jour. Pub. Health*, 22 (1932), No. 12, pp. 1220-1229, fig. 1).—This preliminary report summarizes laboratory and clinical data obtained by the authors in the determination of the antirachitic potency of (1) milk irradiated with a carbon arc lamp, (2) milk from cows fed irradiated yeast, and (3) milk from cows irradiated with a carbon arc lamp. Particular emphasis is given to the third method of increasing the vitamin D content of milk inasmuch as conflicting results had been obtained in earlier investigations on the subject. The method of irradiating the cows is described in considerable detail. Definite protection against rickets was demonstrated in the preliminary clinical data reported, although the milk contained only about 22 units of vitamin D per quart. "The apparent effectiveness in preventing rickets in infants by such a small number of vitamin D units emphasizes the importance of certain unknown and unmeasured factors in vitamin D fortified milk which deserve further consideration and study."

The addition of vitamin D concentrate to milk, T. F. ZUCKER (*Amer. Jour. Pub. Health*, 23 (1933), No. 1, pp. 10-12).—Further details are given concerning the method of fortifying milk with vitamin D, noted below, together with the characteristics of the milk which, in the opinion of the author, distinguish it from other vitamin D milks. Certain questions of public health interest are raised and answered.

The use of vitamin D from cod-liver oil in milk and bread, T. F. ZUCKER (*Science*, 77 (1933), No. 1984, pp. 19, 20).—The author announces the preparation from cod-liver oil of a concentrate of vitamin D free from objectionable taste and odor and suitable for use in fortifying milk and other foods with vitamin D. The process has been patented by the board of university patents, Columbia University, and the right to manufacture and sell the concentrate in the United States, Canada, and Newfoundland has been leased to the National Oil Products Company.

Irradiated milk: The influence of the intensity and character of the radiations on the antirachitic potency, G. C. SUPPLEE, H. H. BECK, and M. J. DORCAS (*Jour. Biol. Chem.*, 98 (1932), No. 2, pp. 769-782, figs. 4).—This paper reports an extension of studies noted previously (E.S.R., 67, p. 490) to the application of lower amounts of energy of different quality to milk under uniform conditions. The radiations used were obtained from carbon arcs of the flaming arc type and quartz mercury vapor arcs of the Hanovia type. The intensity of the direct radiations from each of these sources was varied by changing the amperage of the arc stream while maintaining a constant voltage and by using reflected rays from nickel and chromium reflecting surfaces. Both the character and intensity of the radiations were varied by the use of Corex D and mica filters.

The data are reported in tables showing the relation between the amount of energy applied to the milk and its vitamin D concentration and also in charts on which the calculated numbers of molecules of vitamin D per cubic centimeter of milk were plotted on logarithmic paper against the energy in quanta applied per cubic centimeter of milk.

The total radiations from unscreened sources produced a higher antirachitic potency in the milk than did the filtered radiations. This is attributed to the reduction of total energy applied per unit of time. A definite intensity of radiation within the antirachitic range was found to be necessary for effective activation of the milk. For unscreened sources, this range is given as from approximately 6×10^{10} quanta to 5×10^{17} quanta per cubic centimeter of milk.

Between these limits the effectiveness of equivalent amounts of energy varied with the source of radiation. "The relative effectiveness of an equivalent amount of energy from the different sources was found to be in the following order: C carbon, magnesium carbon, mercury vapor arc, and sunshine carbon, respectively. It should be noted, however, that when time and intensity are considered for practical purposes, the effectiveness of the different sources increases in the following order: Mercury vapor arc, sunshine carbon arc, magnesium carbon arc, and C carbon arc."

Vitamin G in root and leaf vegetables, P. L. DAY (*South. Med. Jour.*, 24 (1931), No. 10, pp. 876-878, figs. 4).—Following the technic as described previously (E.S.R., 66, p. 794), the author has determined the vitamin G content of several root and leaf vegetables purchased as needed at retail markets (Little Rock, Ark.) and fed in the fresh state. The materials used and the values obtained, expressed as Bourquin units, are beets 0.5, beet tops 2.5, carrots 0.5, carrot tops 2.0, potatoes 0.3, spinach (winter) 1.0, turnips 0.5, and turnip tops 3.0 units per gram. These values confirm the general impression that leaf vegetables are richer in vitamin G than root vegetables.

The calcium and phosphorus content of the brain in experimental rickets and tetany, A. F. HESS, J. GROSS, M. WEINSTOCK, and F. S. BERLINER (*Jour. Biol. Chem.*, 98 (1932), No. 2, pp. 625-636).—"Rickets in the rat is associated with a marked decrease of total calcium in the brain. The percentage of inorganic phosphate is similarly decreased. These changes come about in spite of the fact that the diet is high in calcium. The return to normal levels is slow. There is no relationship between the concentration of calcium in the blood and its concentration in the brain. In rickets the total calcium is normal in the blood and diminished in the brain. In parathyroid tetany it is low in the blood and undiminished in the brain."

Magnesium rickets [trans. title], G. MEYER ZU HORSTE (*Klin Wchnschr.*, 11 (1932), No. 43, p. 1796).—Evidence is summarized briefly leading to the conclusion that the addition of magnesium carbonate to a nonrachitic diet produces rickets in rats and rabbits similar to the type produced by an excess of calcium carbonate. In the histological and blood chemistry changes the magnesium rickets resembled infantile rickets and responded to the same curative agents. It is suggested in considering the cause of rickets that attention should be paid to the ratio of calcium and magnesium to phosphorus.

Food supply and pellagra incidence (*Jour. Amer. Med. Assoc.*, 99 (1932), No. 25, pp. 2116, 2117).—Editorial comment is given on the pellagra studies reported by Stiebeling and Munsell (E.S.R., 68, p. 421).

Experimental production of mottled enamel, M. C. SMITH and E. M. LANTZ (*Arizona Sta. Tech. Bul.* 45 (1933), pp. 325-359, pls. 18).—This publication describes, with excellent photographic illustrations, the experimental production of mottled enamel in albino rats, dogs, and guinea pigs.

In rats the condition was produced in three ways, (1) by administering the drinking water or concentrates from the drinking water from a locality where mottled enamel is endemic (E.S.R., 65, p. 596), (2) by feeding sodium fluoride at levels of 0.025, 0.05, and 0.1 percent of the ration, and (3) by injecting the fluoride subcutaneously or intramuscularly.

In dogs the condition was produced by feeding sodium fluoride at levels of 0.025 and 0.05 percent and in guinea pigs at a level of 0.05 percent. Mottled enamel was also produced in a single guinea pig by the subcutaneous injection of 0.6 cc of a 2.5 percent solution of sodium fluoride.

In rats the first indication of dental abnormality was lack of pigment, followed by loss of luster. In severe cases the enamel became corroded and

pitted and sections tended to chip off. In dogs and guinea pigs, the teeth of which are less pigmented and translucent, the chief characteristic of the defect was the corrosion and chipping off of the enamel.

TEXTILES AND CLOTHING

Preparing wool for market, W. M. BUCK (*U.S. Dept. Agr. Leaflet 92 (1933)*, pp. 4, figs. 7).—Practical instructions are given on care during shearing the sheep, and on preparing, tying, and packing the fleece.

The influence of position isomerism in azo dyes upon fastness to light and washing, M. GRIFFITH (*Ohio Sta. Bul. 516 (1933)*, pp. 94, 95).—This progress report lists the dye intermediates which have thus far been prepared for use in the preparation of a series of naphthalic azo dyestuffs to determine the influence of substitution of sulfonic groups on the affinity of the dyestuffs to various types of fibers and the fastness of the dyed fabrics to light and washing.

HOME MANAGEMENT AND EQUIPMENT

[**Studies in home management and equipment in Indiana**] (*Indiana Sta. Rpt. 1932*, pp. 43, 44).—Included in this progress report (E.S.R., 67, p. 637) are a comparison of the efficiency of an insulated gas oven with the electric ovens studied previously, and data on the time spent by rural home makers in kitchen tasks. Current consumption records for one year for electric ranges, refrigerators, washing machines, irons, and a household water pump are also noted.

Factors affecting the performance of kerosene cook stoves, E. B. SNYDER (*Nebraska Sta. Res. Bul. 64 (1932)*, pp. 22, figs. 5).—The purpose of this investigation was to learn the effect of constructional details of the burner and the framework on the performance of kerosene stoves. Six stoves were used, 4 of the long-chimney type and 2 of the short-chimney type. Of the short chimneys one burner used a wick, the other a lighting ring. The effect of (1) draft variations and constructional details and (2) the framework on the heating time and thermal efficiency of stoves was studied.

The results show that the draft of long-chimney burners is greater than that of short and is affected by the height and diameter of the chimney and the size and arrangement of openings for air. Because of the greater draft in long-chimney burners the rate of combustion is higher, resulting in a more powerful but slightly less thermally efficient burner than the short.

Differences in performance of long-chimney burners are due to such constructional details as height and diameter of chimney, size and arrangement of openings for air (particularly in the flame spreader), angle of collar on which the chimney rests, and the distance between the flange and the top of the flame spreader. Such features are fundamental because they direct air currents and mix air with kerosene vapor.

No improvement in heating time and thermal efficiency resulted from interchange of chimneys on long-chimney burners from the same manufacturer. The best results were obtained with the original combination. One combination was slightly superior in performance to the other three. An increase in chimney diameter on one short-chimney burner decreased the heating time but lowered the thermal efficiency. The performance of burners in the cabinet was generally superior to the performance on the stoves. These results suggest the importance of insulation of burners.

Relative distance of grate from chimney top affected heating time and thermal efficiency. Heating time decreases and thermal efficiency increases as

the distance between grate and chimney top decreases. However, there appears to be an optimum distance for each burner because less than this distance results in the formation of soot and odor. The shape and weight of the grate and elevations on it are important factors affecting burner performance. Enclosure of the sides and back improves burner performance, especially where the stove is exposed to outside draft. Long chimneys are not affected by draft to the extent that short chimneys are.

Heating the farm home, A. H. SENNER (*U.S. Dept. Agr., Farmers' Bul. 1698 (1933), pp. 11+18, figs. 7*).—This supersedes Farmers' Bulletins 1174 and 1194 (*E.S.R.*, 44, p. 588; 45, p. 188). It discusses the requirements that should be met and the characteristics of different types of heating systems, and gives advice on selecting heating plants for farm homes and on ways of conserving heat.

MISCELLANEOUS

Report of the Alaska Agricultural Experiment Stations, 1931, 1932, H. W. ALBERTS ET AL. (*Alaska Stat. Rpt. 1931-1932, pp. [2]+26, figs. 4*).—This, the final report on these stations (*E.S.R.*, 67, p. 353), briefly reviews their activities as a whole and reports experimental work for the biennium ended June 30, 1932, for the most part noted elsewhere in this issue. Findings in a survey of the grazing possibilities of the Moose Pass region are also included.

Report of the [California] Agricultural Experiment Station, [1932], C. B. HUGHISON (*California Sta. Rpt. 1932, pp. [2]+106, figs. 17*).—The experimental work not previously referred to is for the most part noted elsewhere in this issue.

Fifty-fifth Report of the Connecticut Agricultural Experiment Station, New Haven, for the year 1931, W. L. SLATE ET AL. (*Connecticut State Sta. Rpt. 1931, pp. XII+850+74, pls. 19, figs. 100*).—In addition to the usual administrative data, this report contains reprints of Bulletins 331-342, previously noted, and of the following circulars: Nos. 81, Requirements for Tree Workers in Connecticut (pp. 1-11); 82, Testing Vegetables for Connecticut: Results for 1931, by D. F. Jones and L. C. Curtis (pp. 13-24); 83, Lawn Seeding and Care (pp. 25-28); 84, The Elm Leaf Beetle Outbreak (pp. 29-34), and 85, Quarantine Restrictions Affecting Shipments of Connecticut Plants, 1932 (pp. 35-43), both by W. E. Britton; and 86, Regulations Concerning Transportation of Nursery Stock in the United States and Canada, compiled by W. E. Britton (pp. 45-74).

[Forty-first and Forty-second Annual Reports of Connecticut Storrs Station, 1929-1930], W. L. SLATE ET AL. (*Connecticut Storrs Sta. Rpts. 1929, pp. [4]+251, pls. 14, figs. 12; 1930, pp. [271], figs. 89*).—The first of these reports consists of Bulletins 162-169, all of which have been previously noted. The report for 1930 contains Bulletins 170-175, previously noted, and Special Bulletin, The Drawing and Handling of Blood Samples for the Serological Diagnosis of Bang's Abortion Disease, noted on page 107.

Annual report of the director [of Delaware Station] for the fiscal year ending June 30, 1932, C. A. McCUE ET AL. (*Delaware Sta. Bul. 179 (1932), pp. 55, figs. 2*).—The experimental work not previously referred to is for the most part abstracted elsewhere in this issue.

Twelfth Annual Report [of Georgia Coastal Plain Station], 1931, S. H. STARR (*Georgia Coastal Plain Sta. Bul. 19 (1932), pp. 104, figs. 8*).—The experimental work not previously referred to is for the most part noted elsewhere in this issue.

Forty-fifth Annual Report of [Indiana Station], 1932, J. H. SKINNER and H. J. REED (*Indiana Sta. Rpt. 1932, pp. 91, figs. 24*).—The experimental

work not previously referred to is for the most part abstracted elsewhere in this issue.

Report of agricultural research [of the Iowa Station] for the year ending June 30, 1932, C. F. CURTISS ET AL. (*Iowa Sta. Rpt. 1932, pp. 128, figs. 12*).—The experimental work not previously abstracted is for the most part noted elsewhere in this issue.

Annual Report of [Nevada Station], 1932, [S. B. DOREN] (*Nevada Sta. Rpt. 1932, pp. 37, figs. 15*).—This report is devoted mainly to a discussion of the history, progress, and problems of the station since its establishment. Data on experiments with sheep are noted on page 93.

Forty-fifth Annual Report [of New York Cornell Station], 1932, C. BETTEN ET AL. (*New York Cornell Sta. Rpt. 1932, pp. 183*).—The experimental work not previously referred to is for the most part noted elsewhere in this issue.

Fifty-first Annual Report of [Ohio Station], 1932, C. G. WILLIAMS ET AL. (*Ohio Sta. Bul. 516 (1933), pp. 129, figs. 12*).—The experimental work reported not previously referred to is for the most part noted elsewhere in this issue.

Report of the Puerto Rico Agricultural Experiment Station, 1932, T. B. MCCLELLAND ET AL. (*Puerto Rico Sta. Rpt. 1932, pp. [2]+24, figs. 8*).—The experimental work not previously referred to is for the most part noted elsewhere in this issue.

Michigan Agricultural Experiment Station Quarterly Bulletin [February 1933], edited by V. R. GARDNER and A. J. PATCH (*Michigan Sta. Quart. Bul., 15 (1933), No. 3, pp. 141-214, figs. 26*).—In addition to articles abstracted elsewhere in this issue, the number includes the following: New Soy Bean Varieties Tested, by C. R. Megee and H. L. Dunton (pp. 152, 153), reporting soybean variety tests; Cost of Producing Eggs in 1932, by P. F. Aylesworth (pp. 157-160), an analysis of the laying flock records of 40 Michigan poultrymen; and Michigan Contest Completes Tenth Successful Year, by E. S. Weisner (pp. 175-177), a cost analysis study of the Tenth Annual Michigan Egg Laying Contest.

NOTES

Colorado Station.—The resignation is announced of Dr. W. G. Sackett, bacteriologist.

Connecticut College.—The name of the institution has been changed by the legislature from Connecticut Agricultural College to Connecticut State College. This change has been made chiefly, it is announced, in order that the name may conform as closely as possible to the activities of the college.

Delaware Station.—Three new brooder houses have been added to the equipment of the poultry plant. P. B. Myers, chemist, has resigned, effective March 1, in order to engage in commercial work in New York City.

Georgia College and Station.—An act of the 1933 session of the legislature appropriates all funds for the State university system, which includes the station, in a lump sum, leaving to the regents an annual allotment between the various units of the system. The regents were also given the right to integrate or abolish different units as may seem best for the State. Under this provision, activities at Athens have been combined in a single institution under Dr. S. V. Sanford as president. Director H. P. Stuckey of the station has also been appointed dean of the College of Agriculture, beginning July 1.

Idaho University.—A gift of 3,646 acres of forest land has been made to the university by the Forest Development Company of Lewiston for development as an experimental forest. The tract is located on Moscow Mountain about 20 miles from the university and will be known as the Moscow Mountain Experimental Forest. While practically all the merchantable timber has been removed, undersized trees were left intact on most of the area, so that natural regeneration will make replanting largely unnecessary. The forest will serve as a field laboratory for the training of forestry students and experimentation in methods of silvicultural management, as well as a game preserve and for recreational purposes.

Purdue University and Station.—A bequest of approximately \$400,000 has been made to the university by the late Hon. William R. Wood of La Fayette, Member of Congress from the Tenth Indiana District for many years.

The regular session of the legislature appropriated to the station \$218,000 per year for the ensuing biennium as compared with \$275,000 for the present biennium.

Kentucky Station.—Wesley Brooks, agent in cream improvement, has resigned.

Minnesota Station.—In cooperation with the county agricultural agents the soils and agricultural engineering divisions of the station are demonstrating the Manguum terrace in soil erosion control in three counties in southeastern Minnesota. One farm has been selected in Houston, Winona, and Goodhue Counties for the demonstration. The station is providing the plan for the terraces and the technical service in building them, the county agent in each instance makes the local arrangements, and the owner of the farm where the demonstration is made supplies the power and labor for building the terrace. The erosion demonstrations will be used as educational projects in the county

in an attempt to lessen the soil losses from erosion, which in many of these counties is of serious consequence.

New Jersey College and Stations.—Announcement is made that the stations have perfected a vaccine for immunizing poultry against infectious bronchitis.

Dr. Gordon T. Nightingale, biochemist in horticulture, is now stationed at the University of Chicago where he is carrying on some fundamental studies on the nutrition of tree fruits. This research represents a cooperative enterprise supported by the stations, the University of Chicago, and the Boyce Thompson Institute for Plant Research.

Recent appointments included the following: Dr. Edgar A. Slagle as research chemist, Marion F. McDowell, extension specialist in child training and parent education, and as research assistants Harold E. Clark (plant physiology), Louis T. Kardos (soil chemistry), Alun J. Pugh (soils), Robert A. Voelker, and John Ziemba.

Association of Land-Grant Colleges and Universities.—The forty-seventh annual convention of this association is to meet in Chicago from Monday morning, November 13, to Wednesday noon, November 15, 1933.

Fifth World's Poultry Congress.—This congress will be held in Roma from September 6 to 15 under the patronage of the King of Italy and with the Italian Ministry of Agriculture and Forestry in charge of arrangements.

Meetings will be held in the Capitol and at the International Institute of Agriculture, with an exhibit of poultry and poultry accessories in the historic Trajan's Markets. The program will be organized into sections of general and genetic questions, physiology, nutrition, and breeding, hygiene and diseases, instruction and organization, economic problems and trade in poultry products, and rabbit raising. At the close of the congress an extensive tour will be made of important breeding regions in northern Italy.

Agricultural Meteorology in India.—A section of agricultural meteorology of the Meteorological Department of India was established at Poona in September, 1932. It is financed by the Imperial Council of Agricultural Research and is provided for provisionally for a period of three years, with Dr. L. A. Ramada in charge.

New Journals.—*Pure Culture Study of Bacteria* is being issued quarterly by the committee on bacteriological technic of the Society of American Bacteriologists, under the direction of the chairman of the committee, Dr. H. J. Conn of the New York State Experiment Station, Geneva, N.Y. Its primary purpose is as a successor to the Continuation Service of the *Manual of Methods for Pure Culture Study of Bacteria*, which was issued at irregular intervals from 1923 to 1931. Each number will consist of two sections, the first containing editorials, reviews of literature, and special articles; the second, one or more revised leaflets for the manual. The object and scope of the journal are set forth in detail in the initial number.

Bollettino del R. Ufficio per i Servizi Agrari della Tripolitania is being published monthly by the Agricultural Service Office of Tripolitania at Tripoli. The initial number contains articles entitled An Extension of Dry Land Agriculture Needed in Farm Management Programs in Tripolitania, by G. Vivoli (pp. 5-7), and The Principal Pastoral Products in Libya, by E. Ducros (pp. 9-17).

Field and Laboratory is being published semiannually by the science departments of Southern Methodist University, Dallas, Tex. The initial number includes an article by M. L. Whitsitt entitled Equipping a Vitamin Laboratory on Depression Funds (pp. 11-14).

EXPERIMENT STATION RECORD

VOL. 69

AUGUST 1933

No. 2

EDITORIAL

FIFTIETH ANNIVERSARY OF THE ALABAMA AND WISCONSIN EXPERIMENT STATIONS

The year 1883 increased to eleven the number of States in which experiment stations had been formally organized in this country. In February Alabama joined North Carolina and Tennessee in the southern group, and in the fall Wisconsin supplemented Ohio in the middle western area. In the Northeast Connecticut, Massachusetts, New York, and New Jersey, and in the far West California and Colorado were the remaining States represented a half century ago.

In both Alabama and Wisconsin considerable experimental work in agriculture had preceded formal station organization. Field trials with fertilizers on cotton were made by the A. and M. College (later the Alabama Polytechnic Institute) in northern Alabama as early as 1875, and at about the same time experimental work was begun on the college grounds at Auburn. About 1880 the work was broadened under the direction of Professor of Agriculture William H. Chambers and later of Dr. W. C. Stubbs, professor of natural science. By 1882 it had included tests of varieties of cotton, wheat, grasses, clovers, peaches, strawberries, and grapes; fertilizer experiments with cotton, corn, and potatoes; and a few chemical analyses of grapes and a kind of sorghum.

In Wisconsin a portion of the university land was set apart as an experimental farm in 1868, and from then until 1880 William W. Daniels, professor of agriculture and analytical chemistry, conducted experiments with varieties of cereals and other farm crops and cultural studies with wheat and corn. A test of Manshury barley, later to become an important crop in Wisconsin, was begun in 1872. In 1880 Prof. Daniels was succeeded in the agricultural field by the late Dr. William Arnon Henry, an account of whose career recently appeared in these columns (E.S.R., 68, p. 429). Prof. Henry soon enlarged the work, some of his early ventures dealing with the utilization of sorghums for sirup and sugar and the ensilage of fodders, for which purpose small special appropriations by the State legislature became available in 1881 and 1882.

These studies aroused much interest, and in 1883 Governor Jeremiah M. Rusk, later to become Secretary of Agriculture, recommended the establishment of an experiment station at the university. This recommendation was approved in an act signed April 2, and the station was formally organized on October 1, 1883. No specific funds were allotted to the station, but the university appropriations were appreciably increased.

For some time the station was operated by a joint committee, consisting of Profs. Henry, William Trelease, and H. P. Armsby, but in 1886 Prof. Henry was made director and Dr. Armsby associate director. Much of the work with cereals and potatoes was still continued, but special emphasis was placed on the development of systems of farming in the State based on dairy husbandry. Feeding experiments with dairy cows, calves, steers, and pigs were undertaken; feeding stuffs, rations, and methods of feeding were investigated; and dairy products were studied, as were problems relative to nutritive ratios and feeding standards and the effect on quantity and quality of milk production of varying proportions of protein to carbohydrates and fat in the ration. Still another line of work to be extensively developed was plant pathological studies.

Meanwhile in Alabama provision had also been made by the legislature for an experiment station at the college. A farm nearby was purchased for its use, and a part of the proceeds of a tonnage tax on fertilizers was allotted for maintenance. Prof. James Stanley Newman was made director upon the organization of the station, with Dr. Stubbs (E.S.R., 51, p. 101) as chemist. The latter began numerous researches, including the composition of the phosphates and greensands of Alabama and the chemistry of sugarcane. Other early work of the station consisted largely of variety and fertilizer tests with field crops, orchard fruits, grapes, and vegetables, and some extensive inbreeding was carried on with Jersey cattle.

The passage of the Hatch Act in 1887 thus found a diversified and well-established program under way in both these States, many creditable accomplishments, and a steadily widening influence. Shortage of space precludes a recounting of their subsequent history at this time, but the opportunity is welcomed to extend to both stations the hearty congratulations of the *Record* for their half century's notable service.

Exercises in observance of the fiftieth anniversary of the Wisconsin Station were held June 3, 1933, in connection with a Farmers' Field Day. At these exercises a telegram was read from the Federal Department of Agriculture felicitating the station upon "its progress in articulating the natural and social sciences and focusing their energies upon rural economic and social objectives and upon the flexibility, foresight, and aggressiveness of its organization which enables it to serve progressively the changing needs of agriculture and rural

life. The spirit of cooperation and vision of the more human problems affecting agriculture which has characterized its development suggest that your accomplishments during the next 50 years will far outdistance the remarkable achievements of your research workers in the past."

The principal speaker for the day was Dr. Eugene Davenport, dean emeritus of the College of Agriculture of the University of Illinois, who took for his subject Research the Master Key to an Advanced Civilization. Dean Davenport paid warm tribute to the State of Wisconsin as a pioneer "in midwest organization in the systematic prosecution of research in the facts and principles that underlie the successful practice of the most fundamental industry of mankind." He pointed out that pioneering means "exploring new territory in the dark, with few sympathizers and fewer helpers but with no dearth of critics," and he gave large praise to such workers as Henry, Babcock, Goss, and Russell, because "whatever progress was made in the early days was the result of individual initiative, even insistence. For at best these men were tolerated, not encouraged. They not only had to build the machinery to serve agriculture through the findings of science but they were obliged to overcome prejudice on every hand; prejudice within the institution at this 'prostitution of education to mere commercial ends', prejudice among the farmers who quite generally assumed that the way to farm is to farm, and that what had served the fathers would also serve the sons, *ad infinitum*."

In spite of these and other difficulties the stations won their way until research had become recognized as an essential element in the field of agriculture. Indeed, as Dean Davenport made clear, "it was this fact of research that first gave farming respectable standing in the academic world." Even more significant progress attended the vitally important matter of gaining and holding the respect and esteem of farmers.

Dean Davenport cautioned against overindulgence in retrospect, however, pointing out that problems lie ahead which "will tax the best talent and the best statesmanship of which this generation is capable if they are to be successfully met and if the advance of knowledge is to keep pace with the demands of an advancing civilization." The idea sometimes encountered that "we have enough of research and of invention to last for a generation or more" was vigorously denied. In reality, he said, "there is never the slightest danger that we shall be too well informed in matters essential to human happiness and progress. Indeed the danger is in the opposite direction, and it is only the conceit of ignorance that would proceed in the dark as new problems arise . . . almost day by day."

Speaking more specifically of agriculture, Dean Davenport went on to say that "we have made a good beginning in agricultural

research. We have laid many a ghost in the form of ancient traditions and faulty practices. We have learned to speak glibly of balanced rations and of vitamins, of unit characters and of genes, of mutations and of bud variations. But there are new puzzles. I see that this station reports that the quality of tobacco is improved by continuous growth on the same land. Why? And why is it that legumes, with rare exceptions, cannot be continuously grown on the same lands? Why? and why the exceptions? Why will that roistering pest the Canada thistle refuse to grow with alfalfa? And why will it grow successfully with alfalfa's first cousin, sweetclover? Why? why? why? An endless array of whys awaits the investigator, for so wondrous in nature that every time he solves one mystery he opens up two questions." In view of these things he raised the direct question, "Are we to be content with these first fruits of research, mulling them over generation after generation like a ruminant chewing its cud, or are we to go forward upon the path which our fathers so thoroughly blazed ahead for us?"

Alleging that just now "the widespread insistent demand for economy threatens the very existence not only of research but of our system of public education on which the structure of our civilization and our form of government rests," Dean Davenport recalled that "our fathers did not establish our national system of education and research out of their abundance." Not only did the system find birth under war conditions but when the "population was only a fourth of what it is today and the wealth but a fraction. . . . Not only that but every enlargement of the work has been made in or near times of distress. The experiment stations were added to the colleges of agriculture before we were out of the woods in the aftermath of the Civil War. The second Morrill Act, as well as the Adams Act, was in close company with a depression, the one of 1893, the other of 1907."

Without in any way minimizing the acute needs of the day for economy in public expenditures, Dean Davenport drew attention to the small outlay in education and research in comparison with what is frittered away by individuals on what he termed "an unnumbered mass of purely personal pleasures." As typical of this situation, he averred that the entire cost of maintaining a large midwestern university some years ago could have been defrayed by the capital dissipated by a single 50-mile pleasure ride of each automobile within that State. Furthermore, he concluded that the question of adequate provision for the needs of today and tomorrow is fundamentally one of relative values. In this conclusion there will be wide concurrence. A wise decision will mean much, not merely to the individual institutions and their personnel, but to the States and the nation which they serve.

RECENT WORK IN AGRICULTURAL SCIENCE

AGRICULTURAL AND BIOLOGICAL CHEMISTRY

Studies on glutelins.—VII, **Cystine, tryptophane, and tyrosine content of glutelins**, F. A. CSONKA (*Jour. Biol. Chem.*, 97 (1932), No. 1, pp. 281-286).—This series of contributions (E.S.R., 65, p. 108) is here extended by an account of determinations of the cystine, tryptophane, and tyrosine content of glutelins isolated by the author's special method from the cereals wheat, rice, corn, rye, barley, and oats. Some modifications are described for the colorimetric determination of cystine by the Sullivan method, and of tryptophane by the May and Rose method (E.S.R., 48, p. 312).

The action of sulfite upon cystine, H. T. CLARKE (*Jour. Biol. Chem.*, 97 (1932), No. 1, pp. 235-248, fig. 1).—From the behavior of cystine in a number of reactions reported upon, the author concludes that in the action of sulfite upon cystine (1) no sulfate is formed; (2) only one half of the cystine is converted to cysteine; and (3) the other half is converted into a salt of S-cysteinesulfonic acid.

The influence of substituent groups on the visible and ultra-violet absorption spectra of amino acids and related substances, G. A. ANSLOW and M. I. FOSTER (*Jour. Biol. Chem.*, 97 (1932), No. 1, pp. 37-46, figs. 4).—In this study of the absorption spectra of selected amino acids and related compounds, it was found that symmetrically formed molecules absorbed light energy selectively, with a weakening of the linkage between the α , β -carbon groups, as in the case of aspartic, glutaminic, and succinic acids, and between the —S—S— groups in cystine. In the case of cystine in HCl solution this disruption resulted in the formation of cysteine chloride and cysteine, and, when the reaction took place in water, cysteine hydroxide and cysteine.

"The frequency of the light which produces dissociation of the carboxyl group is the sum of the electronic frequency, ν_e , in this case the limiting frequency of the Balmer series of hydrogen, and of the natural frequency of vibration, ν_m , of the molecular ion."

The production of hydroxylamine by the reduction of nitrates and nitrites by various pure cultures of bacteria, G. A. LINDSEY and C. M. RUINES (*Jour. Bact.*, 24 (1932), No. 6, pp. 489-492).—A contribution from the North Dakota Experiment Station reports that hydroxylamine has been demonstrated as a reduction product of nitrates and nitrites in broth cultures of *Aerobacter aerogenes*, *Escherichia coli*, *Staphylococcus aureus*, *Bacillus subtilis*, *B. vulgaris*, *B. ramosus*, and *Bacterium anthracoides*. "The fact that these organisms represent such a diversity of types strongly suggests that the production of hydroxylamine is characteristic of the bacterial reduction of nitrites."

The isolation of trimethylamine from spores of Tilletia levis, the stinking smut of wheat, W. F. HANNA, H. B. VICKERY, and G. W. PUCHER (*Jour. Biol. Chem.*, 97 (1932), No. 2, pp. 351-358).—A contribution from the Connecticut State Experiment Station reports an investigation in which it was shown that the amount of the total volatile base and ammonia obtainable from a collection of *T. levis* or *T. tritici* spores depends upon the wheat variety on which the spores have developed, the ammonia content of the spores varying from 54 to

143 mg per 100 g of spores. Distillates from *T. levis* spores were shown to have a higher content of total volatile base and to exhibit greater differences between total volatile base and ammonia than do those from *T. tritici* spores.

"Freshly collected spores of *T. levis* emit an odor resembling that of herring brine. Trimethylamine was isolated from these spores, and it is considered to be the substance responsible for their odor. The trimethylamine content of these spores was probably between 3.6 and 12 mg per 100 g of spores. Spores of *T. tritici*, even when freshly collected, did not emit the odor of trimethylamine, and none of this substance could be detected in distillates obtained from these spores."

The isolation of norleucine, with evidence for its identity, and some thermodynamic data based on the dissociation pressures of the compounds which the isomeric leucines form with ammonia and hydrogen chloride, E. J. CZARNETZKY and C. L. A. SCHMIDT (*Jour. Biol. Chem.*, 97 (1932), No. 2, pp. 333-343, figs. 8).—The isolation of norleucine from spinal cord protein, and the identification of the compound with synthetic norleucine by means of its crystal structure, the crystal structure of its copper and silver salts, and the ammonia and hydrogen chloride dissociation pressures, are recorded.

The ammonia and hydrogen chloride dissociation pressures of the three isomeric leucines were determined, together with values for the change in free energy, the change in heat content, and the change in entropy due to dissociation of the ammonia and hydrogen chloride compounds of the three isomeric leucines. A method for determining the relative amounts of leucine and norleucine when present in a mixture of the two amino acids by titration with gaseous ammonia is described; and it is shown "on the basis of the dissociation pressures and the thermodynamic data that the amino acids which have been studied exist when in the dry state as Zwitter Ionen."

Glucoside formation in the commoner monoses, P. A. LEVENE, A. L. RAYMOND, and R. T. DILLON (*Jour. Biol. Chem.*, 95 (1932), No. 2, pp. 699-713, figs. 3).—The glucoside formation under comparable conditions of all the commoner monoses was studied with the result that for each sugar the proportion of furanoside was found to rise to a maximum and then decrease. The time required to reach this maximum was in general different for each individual sugar, as was also the specific rates of furanoside and pyranoside formation and, usually, the ratio of the two rates.

The formation of methylglyoxal by *Clostridium acetobutylicum*, L. B. PERR and A. M. WYNNE (*Jour. Biol. Chem.*, 97 (1932), No. 1, pp. 177-182).—Methylglyoxal, isolated and identified as the bis-2, 4-dinitrophenylhydrazone, is shown to be a product of the action of dried cells of *C. acetobutylicum* upon magnesium hexosephosphate. It is suggested that the ketoaldehyde is an early transitory product of the normal metabolism of carbohydrate in this species. A preliminary indication of pyruvic acid as a further product of the fermentation of hexosephosphate by this organism is also reported.

Isolation and identification of ergosterol and mannitol from *Aspergillus fischeri*, L. M. PRUESS, W. H. PETERSON, and E. B. FRED (*Jour. Biol. Chem.*, 97 (1932), No. 2, pp. 483-489, fig. 1).—"Ergosterol and mannitol have been isolated from *A. fischeri* (Thom 5041) and *A. oryzae*, Culture 965, grown on an inorganic salt medium containing 15 percent glucose as the source of carbon, and have been identified," in this investigation of the University of Wisconsin.

The melting points and optical rotations of the free sterol, of its acetate and of its benzoate, as well as the absorption spectra of the sterol, were used to characterize the ergosterol. Mannitol was identified by means of its melting

point, by its optical rotation in borax solution, and by the melting points of its tribenzal and hexaacetyl derivatives.

A contribution to the chemistry of *Lactobacillus acidophilus*.—I, The occurrence of free, optically active, dihydroxystearic acid in the fat extracted from *L. acidophilus*, J. A. CROWDER and R. J. ANDERSON (*Jour. Biol. Chem.*, 97 (1932), No. 2, pp. 393-401).—This contribution reports the determination in the crude fat, extracted by alcohol and ether, from *L. acidophilus* of an applicable quantity of free dihydroxystearic acid, $C_{18}H_{36}O_4$.

The acid was shown to be dextrorotatory but very easily racemized. The highest observed rotation was $+7.78^\circ$, but, after the acid had been boiled with dilute alkali it was found to be optically inactive. The acid crystallizes in somewhat indistinct needles from ethyl acetate and melts at 106° to 107° . The barium salt crystallizes from 60 percent alcohol in long, silky needles and melts at 208° to 209° . Reduced with hydriodic acid, the acid was converted quantitatively into stearic acid.

A study of the fatty acids associated with the alpha amylose of corn starch, R. T. SHERMAN (*Diss., Columbia Univ., New York, 1932, pp. 39, pl. 1*).—In this investigation the fatty acids associated with corn starch were found to be hydrolyzed preferentially by acid, by base, and by a lipase-free amylase. The linking between the unsaturated portion of these acids and the carbohydrate was shown to be less stable than that between the saturated portion and the carbohydrate. The action of a lipase-free amylase separated from starch, under certain conditions, a material containing a higher percentage of fatty acid than does α -amylose and consisting of a partially hydrolyzed α -amylose from which only a small portion of the unsaturated acids had been liberated by the amylase.

Compounds of glucose and palmitic acid having the palmityl group at positions 1, 3, and 6 in the glucose molecule were synthesized, the following compounds having been prepared for the first time: 1-palmityl 2, 3, 4, 6, tetra-acetyl glucose, 6-palmityl 1, 2, 3, 4, tetra-acetyl glucose, 3-palmityl monoacetone glucose, and 3-palmityl glucose. The action of an amylase on the above-mentioned derivatives and also on α and β penta-acetyl glucose was tested.

The chemistry of the coffee-bean.—I, Concerning the unsaponifiable matter of the coffee bean oil. Preparation and properties of kahweol, R. O. BENGIS and R. J. ANDERSON (*Jour. Biol. Chem.*, 97 (1932), No. 1, pp. 99-113, figs. 3).—The authors found in the unsaponifiable fraction of the fat extracted from freshly roasted coffee a highly unsaturated, optically very active, and sensitive product designated kahweol, together with one or more sterols. The composition of kahweol corresponded approximately to the formula $C_{30}H_{48}O_3$. The substance apparently contained one hydroxyl group and it melted at 143° to 143.5° ; $[\alpha]_D^{25} = -204.5^\circ$. Catalytic reduction of kahweol gave a compound having a composition $C_{30}H_{52}O_3$ and containing two hydroxyl groups. Reduced kahweol melted at 175° ; $[\alpha]_D^{25} = -67.81^\circ$. The phytosterol isolated was found similar to sitosterol. It appeared to have the composition $C_{27}H_{48}OH.H_2O$; it melted at 138° to 139° ; and the specific optical rotation was -35.58° .

A chemical study of rancidity.—I, Autoxidation of shortenings and crackers, II, Factors influencing the keeping quality of shortenings and crackers, H. O. TRIEBOLD and C. H. BAILEY (*Cereal Chem.*, 9 (1932), Nos. 1, pp. 50-64, figs. 3; 2, pp. 91-106, fig. 1; *abs. in Minnesota Sta. Rpt. 1932, p. 20*).—Of these two contributions from the Minnesota Experiment Station the first reports upon the adaptation of methods for controlled oxidation experiments to the study of the behavior of crackers at 90° C., the length of the induction period in the cases of the various shortenings used in the manufacture of crackers and the

rate of oxygen absorption by these substances being included among the data recorded.

"Keeping quality of crackers was found to be generally related to the length of induction period of the shortenings used in them, but several outstanding exceptions to this relationship were noted. The coefficient of rank of correlation found for series 1 was $+0.504 \pm 0.109$, and for series 2 it was $+0.805 \pm 0.071$. Keeping quality of crackers was found to be more closely related to the length of induction period of the crackers themselves. The coefficient of rank of correlation found was $+0.979 \pm 0.008$."

From the tests described in the second paper it was learned that exclusion of air was much more effective in lessening the tendency of shortenings to become rancid than was refrigeration (10° C.), but crackers stored in carbon dioxide became rancid as rapidly as did those stored in air. Dry air appeared to increase the tendency of the crackers to deteriorate by oxidation, whereas a humidity of 1 percent or more appeared protective.

Reheating crackers for 5-minute intervals at 400° F. for crisping was found markedly to accelerate their oxidative deterioration.

Iodine numbers of shortenings did not appear related to keeping qualities. Free fatty acid content and to a greater extent the smoking temperatures of shortenings were distinctly correlated with keeping qualities. Coefficients of rank of correlation for these factors are given. No relationship was found between the keeping quality of commercial crackers and their H-ion concentration.

Relationships between the structure of organic compounds and their inhibiting effect upon liver esterase. Resemblance to a lyotropic series of anions. D. GLICK and C. G. KING (*Jour. Biol. Chem.*, 95 (1932), No. 2, pp. 477-482, figs. 4).—A series of compounds, in which the CN, I, NO₂, SH, Br, OH, Cl, CO, CONH₂, and NH₂ groups were attached to an amyl radical, conformed in inhibitory effect upon liver esterase to the well-known lyotropic ion series for the analogous inorganic ions in their effect upon protein dispersion in aqueous solution. When a phenyl group was substituted for the amyl group approximately the same order of activity was found. The phenyl radical produced an effect greater than that of the corresponding cyclohexyl radical. Increasing the size of the hydrocarbon ring also caused a greater inhibiting effect, as shown by cyclohexanone and cyclopentanone. Hexylresorcinol produced an inhibiting effect much greater than that of any of the other compounds studied.

The determination of vitamin A in the ether extract of wheat flours [trans. title], A. DANGOUMAU (*Compt. Rend. Soc. Biol. [Paris]*, 111 (1932), No. 38, pp. 796, 797).—From 0.5 to 1 cc of the oils obtained from wheat flour by ether extraction and evaporation under reduced pressure in an atmosphere of nitrogen sufficed as the sole source of vitamin A in curative experiments on rats. Oils prepared similarly, but which had become rancid on standing although kept in closed flasks and protected from light, were without effect.

The antineuritic vitamin.—IV, The preparation of a highly potent concentrate, R. J. BLOCK and G. R. COWGILL (*Jour. Biol. Chem.*, 98 (1932), No. 2, pp. 637-643).—In this continuation of the series of papers noted previously (*E.S.R.*, 67, p. 647), a method is described for obtaining an active concentrate of vitamin B (B₁) by extraction from aqueous alkaline solutions by organic solvents. The method consists essentially in adjusting the H-ion concentration of an aqueous extract of the vitamin to about pH 10 with any common alkali, extracting the solution with an organic solvent immiscible in water, and removing the vitamin from the solvent by treatment with acid. A

description is given of a typical experiment, starting with an aqueous extract of rice polishings and using dry K_2CO_3 to adjust the alkalinity to pH 10, extracting the ice cold alkaline solution with ether at a temperature below $5^\circ C.$, and collecting the extracted vitamin in acid.

The yields are said to be proportional to the amount of organic solvent used per pigeon unit present in the starting material. Possible losses are alkaline destruction, which is decreased at low temperature; oxidation, which is prevented by the use of great care in removing the ether from the acidified concentrate; and mechanical losses. In the authors' experience vitamin B concentrates have been obtained directly from rice polishings or yeast which approximate in potency the concentrates obtained by the Jansen-Donath method up to and including the platinum stage, with yields of approximately 90 percent as compared with about 5 percent for the more elaborate procedure.

Irradiation of nucleic acids and uracil, F. F. HEYBOTH and J. R. LOOFBOUROW (*Nature [London]*, 131 (1933), No. 3299, pp. 92, 93).—It is noted briefly that irradiation experiments with nucleic acids and uracil similar to those reported by Guha and Chakravorty (E.S.R., 68, p. 725) for adenine sulfate have given negative results with respect to the vitamin B₁ potency of the irradiated product. Attention is called to the finding of sulfur in the vitamin B₁ molecule, as reported by Windaus (E.S.R., 67, p. 101) and Kinnersley et al. (E.S.R., 68, p. 725). The authors are of the opinion that it is unlikely not only that any sulfur-free base can yield vitamin B₁ upon irradiation, but also that sulfur can be introduced as an integral part of the molecule from the sulfuric acid bound by the base.

"Aside from these arguments, it is possible that if adenine is the only precursor of vitamin B₁ in the nucleic acids, one might fail to find activity upon irradiating nucleic acids, but succeed in finding it upon irradiating adenine sulfate, either because of the higher concentration of the material capable of activation in adenine sulfate solutions or because the chemical binding of adenine to other constituents might prevent its activation when a part of the nucleic acid molecule."

Hexuronic (ascorbic) acid as the antiscorbutic factor, and its chemical determination (*Nature [London]*, 131 (1933), No. 3304, pp. 273, 274, fig. 1).—This communication includes a summary by T. W. Birch, L. J. Harris, and S. N. Ray of evidence pointing to the identity of vitamin C and hexuronic acid (ascorbic acid), comparative values as determined by chemical and biological tests of the antiscorbutic potency of various foods, and the antiscorbutic activity of hexuronic acid; together with a brief note by Dann dealing with the contention of Zilva (E.S.R., 69, p. 9) of lack of parallelism between the antiscorbutic activity and reducing capacity of vitamin C-containing materials.

The microchemical method used in estimating the hexuronic acid (and presumably the vitamin C) content of foods involved preliminary extraction with trichloroacetic acid and titration against 2,6-dichlorophenolindophenol in acid solution. "Certain naturally occurring reducing reagents, which were found to react when the reducing capacity of foodstuffs was determined according to the Tillmans technic in more neutral solution, did not interfere by this method (special precautions, however, being necessary in the presence of adrenaline). Sensitivity is about 1 part in 30. An amount of vitamin C represented by 0.03 cc of orange juice suffices for an accurate assay, and the determination requires only a few minutes to carry out." The figures thus obtained showed close agreement with the vitamin C value expressed as minimal protective day doses for guinea pigs.

As determined by curative, tooth structure, and preventive methods, 1 cc of orange juice was found to be equivalent to 0.5 ± 0.15 mg of hexuronic acid. The authors recommend the adoption of hexuronic acid as an international standard for vitamin C.

Vitamin C [trans. title], F. MICHEEL (*Naturwissenschaften*, 21 (1933), No. 4, p. 63).—Certain chemical reactions of vitamin C are summarized, leading to the conclusion that the vitamin is either a furan or a cyclopentane derivative.

Constitution of vitamin C, F. MICHEEL and K. KRAFT (*Nature* [London], 131 (1933), No. 3304, pp. 274, 275).—In this note further evidence is summarized, leading to the conclusion that of the two molecular arrangements proposed for vitamin C, as noted above, the furan type conforms most closely to established properties. Structural formulas are given for the vitamin, its enol form, and certain derivatives.

Diffusible serum calcium by high pressure ultrafiltration, H. O. NICHOLAS (*Jour. Biol. Chem.*, 97 (1932), No. 2, pp. 457-464, fig. 1).—A small form of a high pressure ultrafilter with a specified commercial type of cellophane as a membrane and its application to the determination of diffusible serum calcium is described: "With this apparatus the concentration of normal diffusible calcium is somewhat higher than those values obtained by low-pressure methods, but more constant. The normal values obtained by this method show 64 percent of the serum calcium to be diffusible, with the remaining 34 percent firmly and strongly held by the proteins." The author believes his cellophane membranes better than collodion sacs.

The rate of autoxidation of oxidation-reduction systems and its relation to their free energy, E. S. G. BARRON (*Jour. Biol. Chem.*, 97 (1932), No. 1 pp. 287-302, figs. 7).—When the autoxidation by molecular oxygen of a number of reversible oxidation-reduction dyes was examined electrometrically, it was found that at a constant pH value and in the absence of catalysts there is a linear relation between the E' of the dye and the logarithm of the time necessary to oxidize the dye from 2 percent to 50 percent oxidation. This, however, "is not a general rule, as 1-naphthol-2-sulfonate-indo-2,6-dichlorophenol is oxidized at greater speed. On the other hand, hydroquinone is oxidized at lower speed than predicted if the rule was general."

Further conclusions are that "when the E' of the system is changed by changing the pH of the solvent, the same relation between E' and speed of oxidation has been found. When the rate of oxidation of single oxidation-reduction systems is studied, the identical relation exists between the oxidation potential of the system and the rate of oxidation. In such a case even those systems which did not oxidize at the predicted time show this relationship. The rate of oxidation of some of the dyes can be expressed by the equation of reactions of the first order."

The significance of these findings, with their "supposed contradiction to well-known thermodynamic assumptions" is discussed.

Quantitative organic microanalysis, F. PREGL, trans. by E. FYLEMAN (*London: J. & A. Churchill*, 1930, 2 ed., pp. XIV+237, figs. 51).—This second translation (from the third German edition) differs little in plan from the second German and first English editions (E.S.R., 53, p. 714), but many of the chapters have been enlarged and many references to the voluminous recent contributions on microanalytical procedures have been added as footnotes.

A method for the micro gravimetric determination of silica in tissue, J. C. MORGAN and E. J. KING (*Jour. Biol. Chem.*, 95 (1932), No. 2, pp. 613-620, figs. 2).—The authors describe in detail a micro method capable of determining silicon dioxide to 0.01 mg, the procedure being dependent in part on the micro-

chemical procedures developed by Pregl, as noted on page 170, and involving the ashing of the material and volatilization of the silicon dioxide with hydrofluoric acid.

Manometric analysis of gas mixtures, I-VI (*Jour. Biol. Chem.*, 95 (1932), No. 2, pp. 509-611, figs. 5).—These six papers report upon various applications and modifications of the manometric apparatus and method of Van Slyke and Neill, noted on page 172.

I. *The determination, by simple absorption, of carbon dioxide, oxygen, and nitrogen in mixtures of these gases*, D. D. Van Slyke and J. Sendroy, Jr. (pp. 509-529).—Using this manometric apparatus, the gas sample and the nitrogen are measured by the pressures they exert at defined volumes. The carbon dioxide and oxygen are absorbed in alkali and in hyposulfite solution, respectively, in the chamber of the apparatus, the resultant decreases in pressure being noted.

II. *Carbon dioxide by the isolation method*, D. D. Van Slyke, J. Sendroy, Jr., and S. H. Liu (pp. 531-546).—Carbon dioxide was isolated from other gases by shaking the gas mixtures in any desired volume with alkali solution in the chamber of the apparatus. The other gases having been ejected, the carbon dioxide absorbed was set free with acid and determined as in estimations of plasma carbon dioxide content.

"The method is especially adapted to accurate determination of CO₂ when the latter is present in minimal proportions, as in atmospheric air, in which the carbon dioxide content can be estimated easily within 0.0003 volume percent. In respired air the method gives results exact to within ± 0.05 volume percent."

III. *Manometric determination of carbon dioxide tension and pH of blood*, D. D. Van Slyke, J. Sendroy, Jr., and S. H. Liu (pp. 547-568).—"The CO₂ tension is obtained by equilibrating blood with $\frac{1}{3}$ its volume of a gas mixture which contains CO₂ and O₂ in tensions approximating those of average venous or arterial blood. The gas bubble attains the CO₂ tension of the blood, which is then determined by micro gas analysis of the bubble with the method described in the preceding paper. The pH of the plasma is calculated by the Henderson-Hasselbalch equation from the CO₂ tension found in the blood and the CO₂ content determined by analysis of subsequently separated plasma. The maximum errors are ± 2.5 mm of CO₂ tension and ± 0.04 pH; the usual errors are less."

With one sample of blood and an entirely gasometric technic, these determinations give the acid-base balance of the plasma in terms of pH, carbon dioxide or bicarbonate content, and carbon dioxide tension.

IV. *Hydrogen and oxygen by combustion*, D. D. Van Slyke and M. E. Hanke (pp. 569-585).—Report is made upon methods for the determination of hydrogen and oxygen in gas mixtures by the combustion procedure, the gases before and after ignition being measured by pressure. The apparatus was found applicable for micro determinations with 1.5-cc samples of gas, or for macro analyses with samples of 30 to 35 cc. By reducing the pressure in the combustion chamber even the most explosive mixtures could be burned smoothly. Dilution with inert gas as in the usual methods was not necessary.

The maximum error in micro determinations was about ± 0.2 percent of the total gas. In macro determinations of hydrogen the maximum error was ± 0.05 percent, and in oxygen determinations ± 0.03 percent of the total gas.

V. *Hydrogen by absorption with Paal's picrate-palladium solution*, D. D. Van Slyke and M. E. Hanke (pp. 587-597).—The quantitative estimation of hydrogen in gas mixtures by absorption with a colloidal palladium-sodium picrate solu-

tion is described. A complete analysis could be performed in 20 minutes, and with samples of 1.5 cc the maximum error was shown to be 0.2 percent of the total gas.

VI. Carbon monoxide by absorption with blood, J. SENDROY, JR. (pp. 599-611).—A method for the analysis of air containing carbon monoxide in concentration from 0.05 to 0.3 percent is described. The carbon monoxide was first combined, in the chamber of the apparatus, with the hemoglobin of completely reduced blood, and the carbon monoxide content of the blood was then determined by the method of Sendroy and Liu, noted below.

The determination of gases in blood and other solutions by vacuum extraction and manometric measurement, I, II (*Jour. Biol. Chem.*, 61 (1924), No. 2, pp. 523-584, figs. 10).—Of these two papers the first, by D. D. Van Slyke and J. M. Neill, deals with principles of construction and use of the manometric apparatus, the details of apparatus, the details of general technic, calculation, the determination of carbon dioxide in blood or plasma, the determination of plasma carbon dioxide capacity, the determination of oxygen in blood, the combined determination of oxygen and carbon dioxide in blood, the determination of carbon monoxide in blood, the combined determination of carbon dioxide, oxygen, and carbon monoxide, micro analyses, the determination of gases in liquids saturated at high tensions, the determination of dissolved gases in water, and the use of the apparatus for air and general gas analysis. The second, by C. R. Harington and Van Slyke, takes up a modified form of the extraction chamber used with the manometric apparatus to permit the removal of successively added reagents before each gas measurement, together with a technic for determining with the apparatus CO_2 , O_2 , CO , and N_2 , either separately or all in one sample of blood. The reabsorption corrections for CO_2 and CO are eliminated. The accuracy of the oxygen determination was demonstrated by simultaneous gasometric and titrimetric analyses of solutions of hydrogen peroxide.

Gasometric determination of oxygen and carbon monoxide in blood, J. SENDROY, JR., and S. H. LIU (*Jour. Biol. Chem.*, 89 (1930), No. 1, pp. 153-152, fig. 1).—An improved technic for the determination of oxygen and carbon monoxide in a single blood sample by the use of the Van Slyke-Neill manometric apparatus noted above is detailed. It is noted that "apparently, for the mixtures here used, 1-cc and 2-cc samples give results agreeing within the limit of error of the method."

The determination of blood glutathione, G. E. WOODWARD and E. G. FRY (*Jour. Biol. Chem.*, 97 (1932), No. 2, pp. 465-482).—Experiments are reported showing that slightly acid tungstic acid blood filtrates are unsuitable for blood glutathione determinations because of the rapid loss of sulphydryl by autoxidation.

The method for the determination of blood glutathione here described depends upon the preparation of a sulfosalicylic acid blood filtrate and the estimation of the glutathione in this filtrate by titration with 0.001 N potassium iodate. Reduced glutathione values, in a series of 30 normal individuals, were found to cover the range 25 to 41 mg per 100 cc of blood, with an average at 34 mg; in 5 cancer cases, values of 26 to 36 mg were found.

"Zinc reduction of the filtrate gives an increase in this value of 3 to 11 mg, which is assumed to be oxidized glutathione. The only known blood constituent found to interfere in the method was thioneline. This is estimated to produce an error of about 3 mg in the glutathione values."

The determination of ammonia in blood and other biological fluids, O. FOLIN (*Jour. Biol. Chem.*, 97 (1932), No. 1, pp. 141-154, fig. 1).—Various

improvements in details of the aeration method are described, also a new form of absorption tube, so designed as to insure the absorption of the ammonia content of the aeration current. Aeration by passing the air current over a thin layer of the blood sample, rather than through a relatively deep column of the sample, is recommended as a means of avoiding foaming. The question of which alkali should be used to liberate the ammonia content of the blood sample is discussed, borates in any concentration being held to be inferior to carbonates. The value of very small quantities of gum ghatti in preventing cloudiness or turbidity in the use of the Nessler determination of ammonia is emphasized. The preparation of reagents and the working detail of the author's present procedure are given, and the "accuracy and validity of many of the blood ammonia values reported" is brought into question, 30-minute periods of aeration having been shown to be of doubtful effectiveness. The author aerates for from 40 to 45 minutes.

A micro method for the determination of very small quantities of magnesium in biological material [trans. title], K. LANG (*Biochem. Ztschr.*, 253 (1932), No. 1-3, pp. 215-217).—Noting the very low concentrations in which magnesium occurs in many biological materials, together with the fact that magnesium ammonium phosphate has a solubility of about 1:60,000, the hydroxyquinoline derivative of about 1:300,000, the author gives as the basis of his new micro method the solubility of about 1:10,000,000 of the magnesium salt of the ditropaeolin 00. Proteins were found to interfere with the determination, and calcium had also to be removed since it was found to form a very slightly soluble tropaeolin 00 salt. The calcium compound was found more soluble than the magnesium tropaeolate, however.

To carry out the determination of magnesium by tropaeolin 00 precipitation in the case of blood serum, 2 cc of the serum were diluted with 1 cc of the water and 1 cc of saturated ammonium oxalate solution was added. The precipitated calcium oxalate was centrifuged off after 1 hour, 3 cc of the supernatant solution were pipetted into a 10-cc volumetric flask, 2 cc each of 10 percent sodium tungstate and of $\frac{3}{8}$ N sulfuric acid were added, and the volume was completed with water. After filtering or centrifuging, 4 cc of the solution were pipetted into a centrifuged tube of about 10-cc capacity, which was placed in a boiling water bath. To the hot solution were now added 2 cc of a freshly filtered, saturated solution of tropaeolin 00, and the tube was cooled in ice water, thereby precipitating the magnesium tropaeolin compound in crystalline form. The precipitate, after standing 1 hour, was washed at the centrifuge with 4-cc portions of water until the washed water was only straw-colored.

The precipitate was then dissolved in the centrifuge tube in 4 cc of concentrated sulfuric acid, washed quantitatively into a 50-cc volumetric flask, made up to the mark, and colorimetrically or photometrically compared with a similarly prepared standard.

It is noted that a precipitation of magnesium by tropaeolin 00 constitutes a suitable basis also for a larger scale, gravimetric determination. In this case the precipitate is washed, dried at 105° C., and weighed, each 30 mg of the precipitate having been found to contain 1 mg of magnesium.

Determination of iron in cow's milk and human milk, F. REIS and H. H. CHAKMAKJIAN (*Jour. Biol. Chem.*, 98 (1932), No. 1, pp. 237-240).—This method is an adaptation of the authors' procedure involving the colorimetric estimation of ferric ferrocyanide held in dispersion by the use of gum ghatti as a protective colloid, already described (*E.S.R.*, 67, p. 105). The adaptation includes a specific procedure for the complete oxidation of the organic con-

stituents of the milk samples by sulfuric acid digestion with the aid of additions of potassium chlorate solution. The adapted colorimetric procedure is also detailed, and a change in the type of digestion tube is prescribed. Five-cc samples are shown to have permitted accurate results.

Having obtained a sample of milk from four cows milked directly into a bottle, the authors found that its analysis seemed to justify the suspicion that a small part of the iron in milk owes its presence to rusty cans. The results of titration with titanium chloride are shown by the data submitted to have paralleled closely those of the more rapid and more convenient colorimetry.

An iodometric method for the determination of certain of the purines and their derivatives [trans. title], M. Z. GRYNBERG (*Biochem. Ztschr.*, 253 (1932), No. 1-3, pp. 143-145).—By adding 0.1 N iodine in a quantity 2 or 3 times that expected to be reduced, followed by an equal quantity of 0.1 N sodium hydroxide, allowing the reaction from 10 to 15 minutes for completion, acidifying with 5 percent sulfuric acid, and titrating the excess iodine with 0.1 N thiosulfate, the author obtained accurate determinations of guanine, xanthine, and uric acid. Neither adenine nor hypoxanthine gave this reaction. In the cases of guanine and xanthine, two molecules of iodine were found to react with one of the purine. In the case of uric acid, one molecule of iodine reacted with one of the purine compound.

The determination of sugars in plant extracts, T. G. PHILLIPS (*Jour. Biol. Chem.*, 95 (1932), No. 2, pp. 735-742).—In a contribution from the New Hampshire Experiment Station the author presents the results of a critical comparison of the Fehling, Shaffer-Hartmann, and Tompsett reagents with an improved form of alkaline copper solution containing bicarbonate and made less strongly alkaline than the three reagents previously named.

"No one of the four oxidizing reagents is best for all the plant extracts used. As far as the materials studied are indicative, it appears that a choice may be made by comparing Fehling's solution and the bicarbonate reagent. Comparison with the Shaffer-Hartmann reagent is suggested, as because of its convenience it is preferred for use with extracts to which it can be applied. As used in this study, Fehling's solution is not reliable for the determination of amounts of glucose less than 5 mg. It may be used to determine as little as 2 mg of sucrose in the presence of 5 mg or more of glucose. The calculations of sucrose determined in the presence of reducing sugars must be made in a manner suited to the peculiarities of the oxidizing reagent used."

The copper reduction values of mannose under certain fixed conditions, P. H. MOORE, R. W. LLOYD, and G. E. BURGET (*Jour. Biol. Chem.*, 97 (1932), No. 2, pp. 345-350).—Finding that, in attempts to determine mannose in intestinal contents, the low specific rotation of the sugar made optical methods unreliable while a number of the standard copper reduction methods were subject to interference by protein precipitated with the cuprous oxide, the authors developed a method of which the working detail is given. It is based on the reduction of Benedict's solution under specifically prescribed conditions, the reduction being followed by an electrolytic determination of the reduced copper precipitated. The paper includes a table of cuprous oxide and copper equivalents of mannose in single milligrams of mannose from 10 to 30 mg.

For mannose in pure solution the method was shown to be accurate to within 0.1 percent. The conditions for the accurate use of the method for the physiological work for which it was designed are specified in detail.

The colorimetric determination of phosphorus in citric acid extracts of soils, R. R. WARD (*Soil Sci.*, 35 (1933), No. 2, pp. 85-97, figs. 4).—The author treated 100-ml aliquots of his citric acid extracts each with 50 ml of concen-

trated nitric acid, 15 ml of concentrated hydrochloric acid, and 10 ml of 20 percent phosphorus- and arsenic-free sulfuric acid, finding these reagents adequate, on evaporation to fuming under specified conditions, to destroy all citric acid, as well as organic matter from the soil, in extracts of Hawaiian soils; but it is noted that soils carrying more organic matter may require further additions. Iron was found to be most readily eliminated by electrolysis in a cell provided with a mercury cathode. It was found that separation of most of the silica by dehydration with hot fuming sulfuric acid was a great deal more satisfactory than evaporation to dryness with hydrochloric acid and baking; enough of the silica being eliminated to prevent interference. "In the latter method the large amount of titanium present in Hawaiian soils precipitates a considerable amount of phosphorus which will not redissolve in hydrochloric acid, and for accurate work the residue must be fused with sodium carbonate in order to recover the phosphorus." At the close of the evaporation the sulfuric acid could not be allowed to fume vigorously or at a high temperature by reason of the danger of a loss of phosphoric acid. The mercury required to be drained from the cells during electrolysis, or immediately thereafter, to prevent resolution of iron. The color was best developed at the same time in the standard and in the unknown solutions. It was observed also that "blanks should be run frequently, preferably with the addition of a known amount of standard phosphate solution just before developing the color, in order to reduce errors due to deviations from Beer's law at the low concentration of the blank."

AGRICULTURAL METEOROLOGY

The weather: Is it caused or does it happen? M. R. ENSIGN (*Ga.-Fla. Pecan Growers Assoc. Proc.*, 1932, pp. 36, 37).—A periodogram analysis of temperature and barometric pressure over periods of 80 to 120 years in the United States, Italy, and South Africa indicated periodicities of 3, 4, 8, 12, 16, 18, and 29½ years. It is stated that "long range weather forecasts based upon the [periodicity relationships] made from 30 to 60 days in advance for Florida and the Southeastern States, in the past 4 years, have been realized to a high degree."

Sunspots, planets, and weather (*Nature [London]*, 130 (1932), No. 3270, pp. 31, 32).—This is an advance review of the presidential address by I. Jones, director of the Bureau of Seasonal Forecasting in Queensland, to the Queensland Astronomical Society, in which "he seeks for the explanation of abnormal weather not only in the sun spots themselves but also in the conjunctions of the planets [Jupiter, Saturn, Uranus, and Neptune]. Especially important is the conjunction of all four, which occurs at intervals of 164 years and is often associated with world-wide climatic disturbance and severe famines." Although many other factors must be taken into account, a number of examples are given to support the view that in Australia at least the major control of weather is exerted by the sun.

Sunspots and the weather, H. H. CLAYTON (*Bul. Amer. Met. Soc.*, 14 (1933), No. 3, pp. 65-69, figs. 3).—This is an abstract of papers by W. B. Schostakowitsch and H. Mémery. These observers found temperature changes in the same sense as the sun spots. Both investigators found an increase of temperature with an increase of sun spots. Mémery also found a relation between rainfall and sun spots for southern France.

Long-range forecasting, C. G. ABBOT (*Science*, 77 (1933), No. 2002 p. 455).—This is an abstract of a paper presented at the annual meeting of the

National Academy of Sciences held in Washington, D.C., April 24 and 25, 1933. The paper refers to verification of past forecasts of solar variations and presents a detailed forecast of solar variation to December 1934.

Monthly Weather Review, [November–December 1932] (*U.S. Mo. Weather Rev.*, 60 (1932), Nos. 11, pp. 207–235, pls. 11, figs. 7; 12, pp. 237–270, pls. 18, figs. 8).—In addition to the usual detailed summaries of climatological data, solar and aerological observations, observations on weather on the Atlantic and Pacific Oceans and on rivers and floods, and bibliographical and other information, these numbers contain the following contributions:

No. 11.—The Climate of the Lower Rio Grande Valley of Texas, by E. J. Foscue (pp. 207–214) (see p. 177); Aeronautical Meteorology in Germany, by E. R. Miller (pp. 214–216); Meteorological Conditions during the Formation of Ice on Aircraft, by L. T. Samuels (pp. 216, 217); The Section Director and the Cooperative Observer, by M. E. Blystone (pp. 217–219); Convenient Meteorological Records, by G. B. Wurtz (pp. 219, 220); Tree Rings and Wheat Yields in Southern Saskatchewan, by L. B. Powell (pp. 220, 221) (see p. 178); A Review of "The Structure of the Wind Over Level Country," by M. A. Giblett et al., rev. by G. Grimminger (pp. 221, 222); and The Tropical Storm of October 30–November 13, 1932, by C. L. Mitchell (p. 222).

No. 12.—Twenty-nine Months of Solar Radiation of Tucson, Ariz., by G. E. Davis and J. L. McCarthy (pp. 237–242) (see p. 177); Changes in the Solar Constant of Radiation, by F. Baur (pp. 242–246); The Change of Humidity Incident to a Thunderstorm, by W. J. Humphreys (p. 246); Weather Types of the Northeast Pacific Ocean as Related to the Weather of the North Pacific Coast, by T. R. Reed (pp. 246–252); The Remarkably Heavy Precipitation at Henderson Lake, Vancouver Island, British Columbia, by F. N. Denison (p. 252); Snow Rollers, by C. D. Reed (p. 252); West Indian Hurricanes and Other Tropical Cyclones of the North Atlantic Ocean by C. L. Mitchell (p. 253); Preliminary Statement of Tornadoes in the United States during 1932, by R. J. Martin (p. 253); and The Weather of 1932 in the United States, by R. J. Martin (pp. 254, 255) (see below).

The weather of 1932 in the United States, R. J. MARTIN (*U.S. Mo. Weather Rev.*, 60 (1932), No. 12, pp. 254, 255, pls. 2).—The monthly and annual departures of temperature and rainfall for 1932 are shown in tables and charts, and the general weather conditions of the year are summarized as follows:

"The year 1932 averaged slightly above normal in temperature, although it was considerably cooler than 1931. . . . March, October, and December were the months of 1932 averaging below normal. Of these, March had the greatest negative departure and was below normal in nearly every district east of the 110th meridian. January was the month with the greatest temperature variation, the departures ranging from +12.6° in the Middle Atlantic and lower Lake districts to -5.2° in the middle Plateau. Only May and August were warmer than the corresponding months of the preceding year, and in these instances the departures were less than 1°. The northern Plateau district averaged nearest the normal in temperature, the south Atlantic the warmest, and the southern Slope and middle Plateau were the only districts below the annual average.

"Precipitation was abundant in the east Gulf, Florida Peninsula, and southern Slope in 1932. The east Gulf excess was nearly 10 in., the wettest months, compared with normal, being January, September, October, and December. In contrast, the central part of the country, notably the upper Lakes, Plains States, upper Mississippi and Missouri Valleys, was dry. The greatest deficiency for the year, however, occurred in the middle Pacific district, where the total was 10 in. below the average annual fall.

"For the United States as a whole, January, June, August, October, and December were the months wetter than normal, but in no instance did the excess average more than 0.7 in. The driest months, compared with normal, were April and July. In April nearly all districts were below normal and the departures were small; in July the Atlantic coast, south of New England, and the east and west Gulf coasts had rather large negative departures, while other sections were near or somewhat above the monthly average. October was the month of greatest relative change, from -0.4 in. in 1931 to $+0.7$ in 1932. . . . The south Atlantic district was 13.5 in. wetter in 1932 than in 1931 and the east Gulf 19.5 in. The upper Mississippi and Missouri Valleys, the northern and middle Slopes, southern Plateau, and the middle and southern Pacific districts were far drier than in the preceding year; the difference in the middle Pacific region amounting to 7 in."

Climatological data for the United States by sections, [November–December 1932] (*U.S. Dept. Agr., Weather Bur. Climat. Data, 19 (1932), Nos. 11, pp. [198], pls. 3, figs. 3; 12, pp. [202], pls. 2, figs. 3*).—These numbers contain the usual brief summaries and detailed tabular statements of climatological data for each State.

Twenty-nine months of solar radiation at Tucson, Ariz., G. E. DAVIS and J. L. MCCARTHY (*U.S. Mo. Weather Rev., 60 (1932), No. 12, pp. 237–242, figs. 4*).—From a study of intensities of direct solar radiation at Tucson, Ariz., over a period of 29 months, from February 1930 to June 1932, inclusive, the author found variations which showed "very little correspondence with either sun-spot numbers, absolute humidity, air temperature, or barometric pressure, considered separately."

Meteorological observations, [January–February 1933], C. I. GUNNESS and H. JENKINS (*Massachusetts Sta. Met. Ser. Buls. 529–530 (1933), pp. 4 each*).—The usual summaries of observations at Amherst, Mass., with brief notes on the more significant features of the weather of each month.

Our climate: Maryland and Delaware, J. R. WEEKS (*Baltimore: Md. State Weather Serv., 1932, 4. ed., rev., pp. 62, figs. 33*).—This is a fourth edition of the publication previously noted (*E.S.R., 57, p. 612*).

The climate of the Lower Rio Grande Valley of Texas, E. J. FOSCOE (*U.S. Mo. Weather Rev., 60 (1932), No. 11, pp. 207–214, figs. 7*).—From a review of climatic conditions in the Lower Rio Grande Valley of Texas, more particularly in the region of Brownsville, it is shown that "the rainfall varies from more than 30 in. on the coast to about 15 in. at the upper end of the area. Most of the rain comes during the period from April to October, and the remaining part of the year is relatively dry. There is a great fluctuation in the annual rainfall, which is characteristic of the Great Plains type. A period of wet years is followed frequently by a period of very dry years. The drought hazard is so great that irrigation is necessary, particularly with the high rate of evaporation. The winds are dominantly from the Gulf of Mexico, and modify the summer temperature. The winters are quite mild, although occasional cold spells cause great damage to crops. Killing frosts may occur any year, but do not every year. Destructive storms are rare and snow seldom falls."

It is also shown that while the great range in rainfall of the region "has an effect on the natural vegetation to some extent, its significance to agriculture is not as great as might be expected, since the evaporation rate is high enough to make even 30 in. of rainfall insufficient for successful agriculture, and irrigation is practiced throughout the region where topography and soils are favorable. The average annual rainfall, while varying in distribution throughout the

region, is possibly not as significant as the variation in the annual total rainfall."

The rainfall of Malta, with a remark on long-period forecasting, R. C. SUTCLIFFE (*Met. Mag. [London]*, 67 (1932), No. 801, pp. 203-206, figs. 2).—It is shown in this article that the total annual rainfall of Malta is determined by a relatively few days (about 15 per year) of heavy rainfalls. The bearing of this fact on seasonal forecasting is indicated, the conclusion being that "seasonal forecasting is, in some cases (of which the rainfall of Malta is one definite example), not only difficult but quite impracticable."

Climate and corn yield in Indiana, 1887-1930, J. K. ROSE (*Ind. Acad. Sci. Proc.*, 47 (1931), pp. 317-321, figs. 16).—A series of diagrams is given which were prepared by a method of plotting one factor, July rainfall for example, on the abscissas and the temperature or other factor on the ordinates, locating at the meeting point of the two factors for a given year the yield of corn for that year, and placing the doubly smoothed yields on the diagram, shaded progressively lighter to represent progressively lower yields. The method is thought to have some advantages over correlation coefficients, but has the disadvantage that only two climatic factors can be considered on one diagram.

Tree rings and wheat yields in southern Saskatchewan, L. B. POWELL (*U.S. Mo. Weather Rev.*, 60 (1932), No. 11, pp. 220, 221).—From a study of radial tree growth at two points in southern Saskatchewan, by the Douglass method (*E.S.R.*, 60, p. 417) the author concludes that a relation exists between tree growth and wheat yield in that region. The only important cycle found was one of over 50 years, and he concludes that lack of short cycles makes prediction of wheat yields from tree growth impossible.

The influence of climate on German grains [trans. title], **OPITZ** (*Landw. Jahrb.*, 76 (1932), No. 5, pp. 697-731).—Data are reported which show the importance of taking account of climatic and regional factors in the production of grains, especially wheat, rye, and barley, in Germany.

SOILS—FERTILIZERS

[Soil investigations of the Connecticut State Experiment Station] (*Connecticut State Sta. Bul.* 347 (1933), p. 280).—A very brief statement summarizes greenhouse and laboratory work demonstrating the elimination of phosphorus as a limiting factor by the residual effect of previous heavy fertilizer treatments; rate of application experiments for the three principal nutrients; fertilizer experiments on the Windsor field; and lysimeter investigations at Windsor.

[Soil and fertilizer work of the Florida Station] (*Florida Sta. Rpt.* 1932, pp. 63-68, 187-191, 195, 196, 203).—The report discusses, in some instances in more or less detail, work by R. W. Ruprecht on concentrated fertilizers and the effect of fertilizers and soils on the composition of truck crops; the determination by R. M. Barnette of the effect of *Crotalaria* and other green manures on the composition of the soil, and the decomposition of forest, range, and pasture growths to form soil organic matter; and soil reaction studies, and the role of fertilizers and special elements in plant development on the peat and muck soils of the Everglades, by R. V. Allison.

[Soil research at the Rhode Island Experiment Station] (*Rhode Island Sta. Rpt.* [1932], pp. 44-47, 49, 50, 54, 55).—The present report concisely summarizes the work on substitution of green manures for stable manure, fertilizer requirements of crops, effect of manganese and magnesium, soil acidity and liming, crop effects on succeeding crops, soil nitrates and vegetable crops, soil nitrate levels and certain fractions of nitrogen in plant juices, the readily

available phosphate in the soil, and on availability of certain phosphatic fertilizers.

Soil survey of Franklin County, Massachusetts, W. J. LATIMER ET AL. (*U.S. Dept. Agr., Bur. Chem. and Soils [Soil Survey Rpt.], Ser. 1929, No. 9, pp. 45, fig. 1, map 1*).—Franklin County, with an area of 442,240 acres in north-western Massachusetts, includes parts of the southern New England upland plateau and of the Connecticut River Valley lowland. Practically the entire county is well drained, principally by the Connecticut River and its tributaries.

The most extensive of the soils, here mapped and described in cooperation with the Massachusetts Department of Agriculture, as 26 series of 67 types, is Gloucester stony fine sandy loam, which occupies 12.5 percent of the soil area of the county. The remaining groups and types, with the exception of 28 percent of rough stony soils most valuable as forest land, are not individually extensive.

Soil survey of the Basin area, Wyoming, J. T. THORP ET AL. (*U.S. Dept. Agr., Bur. Chem. and Soils [Soil Survey Rpt.], Ser. 1928, No. 27, pp. 48, pl. 1, maps 2*).—The Basin area, forming part of the Big Horn Basin desert region, includes irrigated and irrigable lands bordering the Big Horn River and certain of its principal tributaries, the total acreage being 426,240. The drainage is good under natural conditions, but the under drainage must be supplemented artificially under the conditions imposed by irrigation to prevent surface alkali accumulations.

Ralston fine sandy loam leads in areal extent among the 26 types of 9 series here mapped and described, occupying 16.8 percent of the total area examined. Billings loam follows with 13.2 percent, while 20.5 percent is rough broken stony land. The survey was in cooperation with the Wyoming Experiment Station.

Evaluation of soil types of North Carolina for different crops (*North Carolina Sta. Agron. Inform. Circ. 77 (1933), pp. [1]+26*).—The soils of the State are rated by groups on a productivity scale of 10 for each of the crops most grown in the State.

Soil conservation (*Kansas Sta. Bien. Rpt. 1931-32, pp. 25-30*).—Data are reported on soil fertility as influenced by fertilizers, soil moisture, and rotations; the effect of degree of slope on run-off and erosion; the relation of calcium, phosphorus, and nitrogen in Kansas soils and second-cutting alfalfa hay; soybeans and sweetclover as soil improvement crops; the effect of various soil treatments on the growth and inoculation of alfalfa; the influence of the absolute reaction of the soil solution upon the growth and activity of *Azotobacter*; the soil solution as governed by ion concentration; and replaceable cations and anions in Kansas soils.

Lysimeter studies.—II, The movement and translocation of soil constituents in the soil profile, J. S. JOFFE (*Soil Sci., 35 (1933), No. 3, pp. 239-257, figs. 2*).—Data on the conductivity and reaction of leachings from the new type of lysimeters (*E.S.R., 68, p. 160*) at the New Jersey Experiment Stations for a period of two years showed that during the fall there is an increase in concentration of basic salts in the A_1 horizon. This influenced the conductivity, a rise occurring during October and November. A similar rise in the pH was noted. There was also a definite parallelism between the rise in conductivity and the increase in pH. There was an increase in the total quantity of total solids in the leaching of the second year in A_1 . This was accompanied by a rise in concentration of the solids. The increase in total solid appeared to be primarily of an organic nature.

The alkaline earth bases—Ca and Mg in A_1 —showed a tendency to increase in concentration toward the end of the summer and fall, attaining a maximum in

October and November. The chlorine content of the leachings showed no consistent behavior. The direction of the winds and the Cl content of the rains appeared to govern the quantity of this ion. The S content was fairly high, and it was suggested that the rapid oxidation of the organic sulfur compounds was responsible for augmentation of sulfates in the leachings. The R_2O_3 also increased in concentration during the second year, but not so much as the other mineral constituents. The SiO_2 movement followed the R_2O_3 and the $\frac{SiO_2}{R_2O_3}$ ratio varied from 1.04 to 1.92. The low ratio corresponded to an increase in pH which is in line with the findings of Mattson (E.S.R., 64, p. 418). Of the total solids which reached A_2 from A_1 only 17 percent percolated through A_2 during the first year and 8.3 percent during the second year. There was lower loss on ignition in the total solids from A_2 than from A_1 , indicating a retention of organic matter in A_2 . The concentration of the mineral constituents—Ca, Mg, Cl, S, and R_2O_3 —increased as a rule in the leachings of A_2 as compared with A_1 .

"A comparison of the constituents removed in the leachings through A_2 with those removed from the Cornell lysimeters shows that from 20 to 40 times as much, depending on the constituent, was removed from the Cornell lysimeters. Calculations made on the assets and outgo of Ca from the soil of the Cornell lysimeters show the improbability of such losses under natural conditions. The abnormal condition of the soil material in the lysimeter tanks is responsible for such striking losses. It is inferred that the old type of lysimeters is not suitable for full orientation as to what is actually going on in the soil."

Permeability of soils (*New Mexico Sta. Rpt. 1932, pp. 49-51*).—Attempts to improve the permeability and tilth of a hard impermeable clay loam by the application of acidifying materials and irrigation are briefly noted.

The relation of caliche to desert plants, F. SHREVE and T. D. MALLERY (*Soil Sci.*, 35 (1933), No. 2, pp. 99-113, pl. 1, fig. 1).—Noting the abundance in extensive areas of the southwestern United States of the "caliche" type of calcareous hardpan, of which the formation is attributed primarily to the interrupted penetration of rain water under arid conditions, with the involvement of various modifying factors in different situations, the authors of this contribution from the Desert Laboratory of the Carnegie Institute present data with regard to the moisture content both of the hard layers and of the amorphous masses in which caliche was found to occur in the area examined; with reference to the effect of the caliche layers upon moisture movement in soils; and with respect to the effect of such deposits upon root growth, especially that of the "creosote bush", *Larrea tridentata* (= *Covillea tridentata*), to which the vegetation is chiefly restricted in certain areas of caliche soils.

"The maximum water content is very low for the hard layers of caliche (3.2 to 6.5 percent) but higher for the softer masses (12.9 to 17.3 percent). Even the thinnest layers of caliche greatly retard the upward or downward movement of water in the soil. Evaporation from caliche which is underlaid by water is less than from an equal surface of a porous cup atmometer. Considerable differences of moisture content may exist in bodies of soil separated by a layer of caliche. Caliche will convey water more rapidly from soil beneath it to soil above it than it will from soil to the atmosphere."

Roots were found unable to penetrate the silicified hard layers of caliche, a condition which seriously interfered with their distribution. In cultures of *Larrea* grown in 18 types of soil, varying in texture and in percentage of soft caliche, the poorest growth was made in pure caliche; the best growth in soils containing equal amounts of caliche and sand, loam, or clay respectively,

or in these soils with lower percentage of caliche. The dry weight of the plants decreased with increasing percentages of caliche.

"The percentages of CaO in the ash of the cultured plants varied from 20.24 to 39.19 and those of MgO from 2.06 to 6.02. The varying amounts of caliche in the soils were without influence on the amounts of CaO and MgO in the ash. This result has been confirmed by data from field material taken on soils with and without surface caliche. The fact that the Ca/Mg ratio of the young cultured plants is consistently higher than that of mature plants growing in their natural habitats is due to the higher CaO, and may indicate greater drought resistance on the part of the young plants."

The chemical properties of highly calcareous soils appeared, therefore, to be of less importance than the physical in relation to the growth of *Larrea*.

On the identification of phosphate compounds in soil. S. OSUGI, S. YOSHIE, and N. NISHIGAKI (*Bul. Agr. Chem. Soc. Japan*, 7 (1931), No. 9-12, pp. 84, 85, fig. 1).—The authors found tricalcium phosphate least soluble at pH 7.68, the solubility increasing rapidly on the acid side, slightly on the alkaline. Aluminum phosphate maintained a minimum solubility between pH 4.07 and 6.93, increasing slowly in solubility with increase or decrease of pH value from the limits of this range. The minimum solubility for ferric phosphate was observed between the pH values 3 and 6, its solubility increasing markedly with increase in pH value above this range. The authors estimated the ratios between the various phosphates found in 11 soils by comparing the phosphate solubility curves with those of the pure phosphates. The experiments were considered also to indicate that such a method can be used for following the changes undergone by calcium monophosphate in a soil. A graph shows the solubility curves of the three pure phosphates determined as described.

The distribution, availability, and nature of the phosphates in certain Kentucky soils. M. C. FORD (*Jour. Amer. Soc. Agron.*, 24 (1932), No. 5, pp. 395-410).—The author examined "the distribution or localization of the native and applied phosphates in the fractions of soil separates [of] a representative soil for the purpose of ascertaining in what fraction or fractions of the soil separates the fixation of the applied phosphate occurs." He used the soils of six Kentucky experiment fields for this purpose and for that of tests of the effect of liming on the availability of phosphates, the "relatively available phosphorus" having been determined with the use of carbonated water and of 0.002 N sulfuric acid buffered at pH 3 as solvents.

"Very small amounts of relatively available phosphorus were extracted from the soils of the check plots." These quantities were roughly proportional to the total phosphorus, "which indicates that the native phosphates are essentially of one kind in these soils." Prolonged extraction of the soils gave a solubility of the native phosphates approximately equivalent to that of dufrenite. The use of lime did not seem to influence the availability of the native phosphates.

"The availability of superphosphates varies with the capacity of soils to fix phosphates in relatively insoluble and unavailable forms. On this basis, the soils studied may be divided into two groups. The first group of low capacity in this respect includes the DeKalb silt loam at Berea, the Decatur silt loam at Russellville, and the Memphis silt loam at Mayfield. The second group of high capacity in this respect includes the Tipton silt loam at Greenville, the silt loam at Campbellsville derived from Waverly shale, and the silt loam at Fariston derived from Eastern Coal Basin shale. The use of lime reduces the rate of fixation into relatively insoluble phosphates in all of the soils, but equal applications of lime are much more effective in this respect on soils of the first group than of the second group."

The use of lime reduced the rate of solution of rock phosphate in all of the soils, more in the first than in the second of the groups above named, however. "Lime exercises a positive influence on crop response to rock phosphate on soils of the first group and a negative or neutral influence on soils of the second group. In the soils of the second group, where a high capacity exists for fixing phosphates in relatively insoluble forms, the rate of solution of rock phosphate is also high but a deficiency in readily available phosphorus exists, due to its rapid fixation as relatively insoluble and unavailable phosphates."

Some observations on base exchange in organic materials, J. F. MULLER (*Soil Sci.*, 35 (1933), No. 3, pp. 229-237).—In the work recorded in this contribution from the New Jersey Experiment Stations samples of from 1 to 5 g. of various peat materials, of leaf mold, of rotted wood, of oak leaves, of bagasse, etc., were treated with 400 cc each of 0.2 N barium acetate solution, were twice leached with normal barium chloride solution, were washed chloride-free with distilled water, and were finally leached with 400 cc of normal ammonium chloride in the filtrate of which the displaced barium was determined. The base exchange properties of various similar materials after hydrolysis either with sulfuric acid 80 percent or concentrated, or with 10 percent sodium hydroxide solution, and after oxidation either with chlorine in a postassium chlorate-hydrochloric acid solution or with an alkaline solution of potassium permanganate were determined. Several of these natural organic materials were shown to have considerable base exchange capacities. Decomposition by natural processes increased the base exchange in straw and manure. The base exchange of several organic materials was markedly altered by chemical treatments.

"It is concluded that under the present methods of drastic chemical treatments required for the isolation of the various fractions of organic materials, the property of base exchange should be assigned to certain groups, such as hydroxyl or carboxyl, rather than to specific chemical substances."

Influence of organic matter on crop yield and on carbon-nitrogen ratio and nitrate formation in the soil, A. W. BLAIR and A. L. PRINCE (*Soil Sci.*, 35 (1933), No. 3, pp. 209-219, pl. 1).—At the New Jersey Experiment Stations legume and nonlegume crops were grown in Sassafras loam in cylinders without added organic matter and with rye straw, cut fine, varying in quantity from 1 to 8 tons an acre. Complete fertilizers were used for most of the work, though in certain series nitrogen was entirely omitted and in others extra quantities of nitrogen in the form of nitrate of soda were used.

With the larger applications of rye straw the yields of nonlegume crops were frequently less than the yields on check cylinders. This depressed yield with heavy applications of straw did not occur when legume crops were grown. Likewise there was little or no depression when extra applications of nitrate of soda were made. When no rye straw was used, however, larger yields were obtained in certain cases from those cylinders which had received the heavy application of straw the previous year than from the check cylinders, thus showing that the injurious effect of the straw was temporary rather than permanent.

The rye straw had little influence on the percentage of nitrogen in the crop; determinations made on samples of soil showed a gradual increase in total nitrogen, organic carbon, and organic matter as the amount of organic matter applied was increased.

"With certain exceptions the carbon-nitrogen ratio was not greatly influenced by the 1- and 2-ton applications of straw, but with 4 and 8 tons to the acre a wider carbon-nitrogen ratio was found. The heavy applications of nitrate of

soda have tended to keep the soil reaction near the neutral point. Where no nitrate was used the soil is gradually becoming more acid. Nitrate determinations made at intervals during the period indicate that an abundance of organic matter may depress nitrate formation."

Influence of rye and oat straws upon the growth and yield of certain vegetables, B. E. GILBERT and F. R. PEMBER (*Soil Sci.*, 35 (1933), No. 2, pp. 115-122).—This contribution from the Rhode Island Experiment Station presents new evidence showing the inhibitory effect of large quantities of poorly decayed organic matter upon plant growth. By the use of rye and oat straws of different composition and stage of decomposition and at various rates of application, the effects of these sources of organic matter in connection with the growth of lettuce, celery, beets, carrots, onions, and spinach were evaluated. The pot tests indicated that such resistant organic matter sources have doubtful value as substitutes for stable manure, this being true especially when the nitrogen content of the straws is very low; and that, although it may be possible to balance the inhibitory effect which accompanies the decomposition of low nitrogen straws by very large applications of nitrogen, these are of necessity so large as to be out of reason for field practice.

Relation between carbon dioxide and elemental nitrogen assimilation in leguminous plants, P. W. WILSON, E. B. FRED, and M. R. SALMON (*Soil Sci.*, 35 (1933), No. 2, pp. 145-165).—The authors of this contribution from the Wisconsin Experiment Station report experiments on inoculated clover plants grown on agar and in sand in a closed system and provided with atmospheres which contained 0.03, 0.1, 0.2, 0.4, and 0.8 percent carbon dioxide. In general, as the carbon dioxide concentration in the atmosphere was increased the leaf area, length of tops, stockiness of plant, excess of carbohydrate, and number of nodules formed were increased. Raising the carbon dioxide content of the atmosphere from 0.03 (air) to 0.1 percent resulted in a pronounced improvement in the growth characteristics named, but further increments in the carbon dioxide concentration did not induce correspondingly greater development.

Clover plants grown in agar and supplied with atmospheres containing 0.1 percent or more carbon dioxide showed an increase both in the dry weight and in the quantity of nitrogen fixed, when compared with the controls supplied only with air. However, the gain in nitrogen was relatively less than that in dry weight, and this difference caused the plants receiving additional carbon dioxide to have a lower percentage of nitrogen than the controls. When the plants were grown in sand, the lag in nitrogen fixation as compared with carbon assimilation did not occur until the carbon dioxide content of the atmosphere had been raised to about 0.4 percent. "The difference between plants in agar and in sand, when furnished with small increments of CO₂, is believed to be related to the lower rate of gas exchange of the roots of plants in agar."

Changes in soil biochemical processes under the influence of clover culture [trans. title], N. N. SUSHKINOI (SUSHKINA) (*Izv. Akad. Nauk S.S.S.R. (Bul. Acad. Sci. U.R.S.S.)*, 7. ser., 1931, No. 9, pp. 1219-1253, figs. 4; *Eng. abs.*, pp. 1252, 1253).—The Nosovka chernozem soils on which were carried out the experiments reported in this paper are described as formerly saline, though now desalinized lands, showing a very low productivity which appears due to an accumulation of toxic, incompletely oxidized compounds; the soils being also impoverished with respect to bacterial microflora. By the introduction of clover into the rotation grown on such soils, productivity was much improved and the biochemical soil processes were apparently restored to their normal course. The physical properties of the soil were improved, microbiological

activity and plant growth were accelerated, and yields correspondingly increased.

The effect of lime on the growth and activity of soil micro-organisms [trans. title], J. C. BLES (*Landbouwk. Tijdschr. [Amsterdam]*, 44 (1932), No. 555, pp. 448-455).—A brief general introductory statement is followed by short sections summarizing and commenting upon the more important work thus far placed on record as to the effect of lime on the protozoa, the fungi, and the bacteria of the soil (including the formation of ammonia).

Fungi isolation from Manitoba soil by the plate method, G. R. BISBY, N. JAMES, and M. TIMONIN (*Canad. Jour. Res.*, 8 (1933), No. 3, pp. 253-275, figs. 2).—The authors examined the fungus flora of 75 surface soils sampled in various parts of Manitoba, finding, in part, that "the population of fungi in these soils is abundant and varied despite climatic conditions which might appear unfavorable. Forty-four genera and 100 species of fungi have been identified and the relative frequency of each determined. It has been found that the methods of soil microbiology give data regarding the parasitic as well as the saprophytic fungi in soils; that *Trichoderma lignorum* parasitizes certain other fungi, and thus may play a part in keeping in check the pathogenic fungi within a soil; and that the addition of chemical fertilizer to a soil results in a prompt and consistent increase in the fungus flora."

Movement of fertilizers in Carrington loam, O. E. OVERSETH (*Jour. Amer. Soc. Agron.*, 25 (1933), No. 3, pp. 202-216).—The author of this contribution from the Iowa Experiment Station determined the total loss of weight and the extent of the leaching out of individual constituents of samples of 16 percent superphosphate, of 3-12-3 complete fertilizer, and, in a part of the work, of fertilizers of various formulas, by weighing out the fertilizers in double cheese-cloth bags, placing these packages in soil under controlled temperature and moisture conditions in a greenhouse, reweighing and analyzing the contents of the packages at various intervals. The extent of the distribution through the soil and the concentration at various distances from the point of application were also considered.

Ammonium sulfate moved out of the complete fertilizer mixtures rapidly. The movement of phosphorus was rapid during the first two days in the soil and then was noticeably retarded. The movement of potassium was not quite as rapid as the movement of nitrogen. Ammonium sulfate apparently reduced the movement of phosphorus out of the phosphate, but did not show any effect on the movement of potassium. Neither did potassium chloride appear to influence the movement of phosphorus or nitrogen. The rate of movement of nitrogen in the soil was less and slower under fertilizers high in phosphorus content. The lateral movement was influenced to about the same extent. The movement of phosphorus in the soil was increased by the greater amount of nitrogen present in the complete fertilizer as sulfate of ammonia. The presence both of ammonium sulfate and potassium chloride apparently facilitated the movement of phosphorus in the soil.

"The change in the phosphate in the complete fertilizer placed in the soil appeared to be rather sudden. Indications from the data presented are that monocalcium phosphate did not remain long in the complete fertilizer in that form. The first reaction that took place was the solution and outward movement of the readily soluble monocalcium phosphate. The remaining monocalcium phosphate then formed dicalcium phosphate, a reversion taking place within the fertilizer sample immediately after moisture from the surrounding soil had diffused into the fertilizer. After a 21-day period, chemical analyses showed that about 80 percent of the phosphorus in the complete fertilizer was

in the dicalcium phosphate form. A large part of the remaining phosphorus was present as tricalcium phosphate. . . .

"The effect of the movement of soluble salts in the 4-16-4 fertilizer on the conductance of an electrical current was noticeable between the first pair of electrodes located 1 in. directly below the fertilizer. A significant decrease in resistance that continued throughout the experiment indicated constant salt movement in the soil between these electrodes. The diffusion of soluble salts in the immediate vicinity of the fertilizer zone was noted within the short time of 2 hours after the fertilizer was placed in the soil. At the 2- and 3-in. depth the soluble salt diffusion due to the movement of soil moisture was not significant even at the end of 150 hours."

The degree of humification in manures measured by the use of hydrogen peroxide, J. G. SHRIKHANDE (*Soil Sci.*, 35 (1933), No. 3, pp. 221-228).—At the Rothamsted Experimental Station little difference was found between 3 percent and 6 percent solutions of hydrogen peroxide with respect to their action upon artificial manures. Such solutions attack undecomposed straw to some extent.

In comparing the action of peroxide and water on straw and manures of different origin it was found that (1) the effect of peroxide is more than a solvent action such as is the case with water, (2) the water extract contains more organic matter than the peroxide extract, (3) water appears to extract more inorganic substance than peroxide, and (4) the amount of organic matter in the peroxide treatments is generally constant whereas that in the water shows greater variation.

Artificial manures could be arranged in order of rotting according to the figure for apparent degree of humification derived from loss in weight due to extraction with H_2O_2 . Higher initial moisture content in a series of artificial manures resulted in a greater degree of humification. In a series of artificial manures made from straw and various sources of nitrogen the degree of humification could be arranged in the order proceeding from the highest to the lowest: $\{\text{NaNO}_3$ and $(\text{NH}_4)_2\text{CO}_3\}$, casein, peptone, urea, $(\text{NH}_4)_2\text{SO}_4$.

A review of researches on nitrogen fertilization in relation to economic crop production, with special reference to future investigations, W. P. KELLEY (*Jour. Amer. Soc. Agron.*, 25 (1933), No. 1, pp. 51-64).—This contribution from the University of California reviews United States and foreign work on the effect of nitrogen on crop yields, effect of nitrogen on the quality of the crop, the relation of nitrogen to other elements, effect of different nitrogen fertilizers, effect of nitrogen on legumes, chemical and physical effects of nitrogen fertilizers, and nitrogen gains and losses from soils. A summary presents some general conclusions drawn from the conspectus.

Experiments on the use of aqueous solutions of ammonia as a nitrogenous fertilizer [trans. title], S. DOLDI (*Ann. Tec. Agr.*, 6 (1933), No. 2, I, pp. 146-161).—Aqueous ammonia solution was found a cheaper source of nitrogen in the conditions prevailing where the experiments here reported were carried out than the solid nitrogen compounds, and when applied to neutral soils in pot tests it gave dry matter yields superior to those obtained by treatment either with ammonium sulfate or with sodium nitrate. The yields were less in acid soils, however. The nitrogen content of the plants grown on neutral soils was the same in the case of each of the three sources of nitrogen. Of the plants grown on acid soils those given the ammonia solution contained twice as much nitrogen as those provided with nitrogen either from ammonium sulfate or from sodium nitrate. The ash content of the plants varied independently of the source of the nitrogen. The composition of the ash was variable, being most affected by the nature of the soil. The sulfur content

of the ash was greater in the case of the plants grown in soil treated with ammonium sulfate but was not otherwise affected by the nature of the source of nitrogen. Solutions either of ammonia or of sodium nitrate had no effect upon the reaction of a soil bearing vegetation, but ammonium sulfate solution decidedly lowered the pH of the soil.

The water solubility of Thomas slag phosphate [trans. title], H. OSVALD (*Svenska Mosskulturför. Tidskr.*, 46 (1932), No. 2, pp. 141-143).—Samples containing each 100 mg of total phosphoric acid [anhydride?] were treated in each extraction with 500 cc of distilled water. The first extraction dissolved out only a small quantity of phosphoric acid (average about 0.9 mg) but considerable quantities of lime, so that the reaction of the extract was strongly alkaline. After the first three extractions, however, the reaction became practically neutral and remained such through a series of 30 extractions. From one of the samples the first three extractions dissolved out a total of 5.7 mg, the twenty-eighth to the thirtieth, 5.4 mg. From another sample the first three extractions removed 3.1, the last three 5.5 mg of phosphoric acid. The total removed in the 30 extractions was from the first sample 68.2 mg, from the second sample 60.5 mg. The reactions after 30 extractions were, respectively, pH 6.6 and pH 6.5. The citric acid solubility was 93 percent of the total in the first and 89 percent in the second sample, the 30 water extractions thus removing 73.3 and 68 percent, respectively, of the citric acid soluble phosphate.

It is concluded that Thomas slag phosphate will be well utilized in acid soils, with an after-effect longer than that of superphosphate, whereas in slightly alkaline soils of relatively high lime content the Thomas phosphate will be of slight effect by reason of its low solubility at alkaline reactions in the presence of lime.

Assimilation of phosphorus and potassium by barley plants grown according to Neubauer procedure and in undiluted soil, J. W. AMES and K. KITSUTA (*Soil Sci.*, 35 (1933), No. 3, pp. 197-207).—In the Neubauer experiments (*E.S.R.*, 53, p. 319) here reported in a contribution from the Ohio Experiment Station, the seedlings grown respectively in small quantities and in larger samples of the undiluted soil gave different indications as to the phosphorus and potassium requirements of the soil. When 100 barley plants were grown, on the one hand, 18 days in 100 g of the soil diluted with 300 g of pure quartz sand, and on the other hand, in 9 lb. of the undiluted soil, there was found an inverse relation between the percentage content of phosphorus and potassium in plants and the amount of soil. The plants grown in 100 g of soil contained more phosphorus, whereas the potassium content was considerably greater in plants grown in the larger amount of soil. Application of the plant analysis method for determining the available phosphorus supply in soils of fertility experiment plats did not furnish significant indications of increased amounts of phosphorus residual from superphosphate, bone meal, and basic slag. Available phosphorus supplied by superphosphate when the barley was planted was more consistently indicated by the phosphorus content of plants and its removal from the larger amount of soil.

Both the Neubauer seedling procedure and the method of growing plants for the same length of time in undiluted soil as generally followed in vegetative tests showed there was a reserve supply of potassium in soil fertilized with muriate of potash. The plant analysis method proved to be satisfactory for furnishing information regarding the available potassium reserves from previous fertilizer treatment, but failed to indicate differences in the phosphorus supply of unfertilized and phosphated soils.

Barley grown in 100 g of soil in accordance with the Neubauer procedure appeared to have the capacity to assimilate a considerable quantity of potassium from sources other than the exchangeable potassium content of the soil.

Differential response of certain soil types to applications of calcium arsenate. W. R. PADEN (*Jour. Amer. Soc. Agron.*, 24 (1932), No. 5, pp. 363-366, figs. 4).—The tests here reported were made on Davidson clay loam and Durham coarse sandy loam. These soils are stated to "differ widely in their physical and chemical properties," and to have been subjected to the use only of very small quantities of calcium arsenate, cotton and cowpeas being used as test plants. On the basis of the trials described, "it is possible to arrange some of the more important soils of the Piedmont section into groups according to their expected response to the additions of arsenic. Dark-colored soils may be expected to be more tolerant than light-colored soils; likewise fine-textured soils may be more tolerant than coarse-textured soils. The data indicate that calcium hydroxide may reduce appreciably the arsenic injury on Durham soil."

Kinds and amounts of different fertilizers North Carolina farmers used during the fiscal year, 1931-32. C. B. WILLIAMS (*North Carolina Sta. Agron. Inform. Circ.* 79 (1933), pp. [1]+5).—The circular is essentially a tabulated tonnage report of complete fertilizers, of two-component fertilizers, and of raw materials.

Registration, labeling, inspection, and sale of commercial fertilizer, 1932. F. B. MUMFORD and L. D. HAIGH (*Missouri Sta. Bul.* 321 (1933), pp. 30).—This bulletin records the usual information on the 1932 fall collection of fertilizer samples (E.S.R., 68, p. 309).

AGRICULTURAL BOTANY

The dispersal of plants throughout the world. H. N. RIDLEY (*Ashford, Eng.: L. Reeve & Co., 1930, pp. XX+744, pls. 22*).—"This book is an attempt to collate and compare the observations and records on the subject. . . . The complete story of dispersal, however, is not yet finished, and there is still a large field of work for observers. . . . Throughout this work I have used the old-fashioned scientific names of plants and animals as popularly employed before the system of modern alterations in nomenclature came into use, as it is easier to understand what plant or animal is referred to by these names. . . . A large number of really unnecessary new words have been invented in ecological works for all kinds of conditions, states, and phenomena of dispersal and distribution. These I have excluded altogether, except where they actually convey a fact or theory which cannot be stated otherwise than by a long sentence."

Plant physiology (5. *Internatl. Bot. Cong., Cambridge, 1930, Rpt. Proc.*, pp. 420-460).—Papers on carbon metabolism of the higher plants included Physiology of the Organic Acids in Green Plants [trans. title], by W. Ruhland; Induction Periods in Photosynthesis Experiments, by G. E. Briggs; The Connection between the Oxybiotic and Anoxybiotic Respiration in Plants, by P. B. Jensen; Growth Curves of Pythium and Raphanus, by A. E. Navez; Respiration and Oxygen Concentration, by F. F. Blackman; The Activation of Amylase by Cyanide in vitro and in vivo, by C. S. Hanes and J. Barker; and Inter-relationships of Organic Acids and Carbohydrates in Succulent Plants, by T. A. Bennett-Clark; Papers on the permeability and osmotics of the plant cell included Permeability of Protoplasm [trans. title], by L. Jost; Plasmolysis and Swelling in Plant Cells (Moving Pictures), by S. Prát; The Course of Plasmolysis and Permeability to Water [trans. title], by K. Höfler; The "Multiple Partition Coefficient"

Theory of Penetration, by M. Irwin; Permeability of the Cell Wall for Inorganic Kations and Anions, by V. Úlehla; The Permeability of Plant Membranes to the Halogens, by C. A. Shull; and Permeability to Electrolytes of A Thick Natural Membrane [trans. title], by L. Brauner. Papers on the mineral nutrition and growth of higher plants included Spectroscopic Methods in the Study of Mineral Nutrition, by H. G. Lundegårdh; Phosphoric Acid Concentration and the Growth Rate in Maize, by M. Korczewski; The Mineral Nutrition of Barley, by F. G. Gregory; The Selective Absorption of Potassium by Plants, by E. Demoussy; and The Absorption of Mineral Constituents by Plants from Insoluble Compounds, by K. Bassalik. Papers on methods of investigation of protoplasmic organization included Bio-electric Potentials, by W. J. Osterhout; Electrical Resistance of Single Multinucleate Cells, by L. R. Blinks; The Mechanism of Electrical Response, by H. H. Dixon; The Connection between Growth-producing Substances and Plant Movements, by F. A. F. C. Went; Activities in the Plant Cell As Indicated by X-Ray Methods, by O. L. Sponsler; Treatment of Living Cells with Coloring Materials and Research Reagents [trans. title], by H. Pfeiffer; The Integration of Plant Behaviour, by F. Keeble; and On the Influence of Leaves and Buds on Regeneration Processes in Woody Cuttings, by H. A. A. van der Lek. Papers on the growth and development of higher plants included The Action of A High Tension Electric Discharge on the Growth of Barley, by V. H. Blackman; Nutrient Ions and Enzymic Activity of Plants, by G. Doby; The Range of Structural and Functional Variation of the "Traps" of Utricularia, by F. E. Lloyd; The Transport of Metabolites and Salts in Higher Plants, by T. G. Mason and E. J. Maskell; Some Observations on the Behaviour of Cotton Roots in Deep Soil, by J. Templeton; and The Root As An Indicator of Subsoil Variation, by W. L. Balls. Papers on nitrogen metabolism of higher plants included The Function of Xanthine Derivatives and Alkaloids in the Metabolism of the Higher Plants, by T. Weevers; Movement of Urea in Plants [trans. title], by G. Klem; and Moving Pictures of Plant Movements and Development, by V. Úlehla.

Physiological studies in plant nutrition (*Florida Sta. Rpt. 1932, p. 177*).—Data are reported as to chlorine assimilation in sugarcane and other plants.

A new method of germination and the influence of hydrogen ion concentration on the germination and growth of *Helianthus annuus* and *Lycopersicum esculentum*, R. C. MALHOTRA (*Jour. Indian Bot. Soc., 9 (1930), No. 4, pp. 218-239, pls. 2, figs. 3*).—A new method of germination is described in which renewal of solutions is possible without molesting or disturbing the seeds, and the influence of H-ion concentration has been studied by this method. It is found that pH 6 appears to be more favorable for the maximum germination of these seeds both in percentage of germination and in the weight gain per unit weight of seeds. The data presented suggest that acidity in the lower ranges is comparatively less harmful in the germination stage than in growth, although this tendency is not very significant. It was also found that pH 6 was favorable for the maximum growth of these plants.

Chemical and physiological studies of after-ripening of seeds of *Rhodytypos kerrioides*, F. FLEMION (*Amer. Jour. Bot., 19 (1932), No. 10, p. 837*).—When mixed with dampened peat moss better results were secured if seeds were stratified for 1 month at 25° or 30° C. before stratification at 5°. Seeds kept dry for several months at room temperature germinated more strongly than seeds submitted directly to low temperature. A study of excised embryos showed that both embryo and seed coat functioned in dormancy. Analyses during afterripening showed an increase in catalase, peroxidase, and lipase activity, water absorption power, nitrogen soluble in 80 percent alcohol, and

in titratable acid and sucrose. The ether-soluble fraction decreased as after-ripening proceeded.

Dormancy in seeds of *Symphoricarpos racemosus*, F. FLEMION (*Amer. Jour. Bot.*, 19 (1932), No. 10, pp. 836, 837).—Treatment of seeds with concentrated sulfuric acid from 45 to 60 minutes before stratification in moist peat moss held at 5° C. (41° F.) resulted in about 40 percent germination at the end of 7 months. Without acid treatment seeds stratified for 4 months at 25° or 30° before stratification at low temperature gave 75 to 80 percent germination. From the results it is concluded that both toughness of seed coat and embryo dormancy are involved in delayed germination.

The altered rate of growth of *freesia* corms, W. P. MORGAN and L. J. MICHAEL (*Ind. Acad. Sci. Proc.*, 46 (1930), pp. 103-105).—"Chemical treatment of *freesia* corms gives only a temporary stimulus to growth. Once growth is established the plant is controlled by other factors in its reaction with its environment."

Experiments on transpiration.—I, The daily water balance of plants in arid regions, R. S. INAMDAR and B. M. DABRAL (*Jour. Indian Bot. Sci.*, 9 (1930), No. 1, pp. 1-30, figs. 5).—In observations recorded as to the water balance of pot plants in the arid climate of Benares, it was noted that there was normally a daily rate of water loss per unit area of evaporating surface in spite of the fluctuations in the evaporating capacity of the atmosphere within certain limits. This maximum value was reached at a relatively low value of evaporating capacity of the atmosphere, about 37 percent of the maximum evaporating capacity obtained under normal conditions. The significance of these observations is indicated. A theoretical discussion of the internal conditions in the plant concerned in the daily water balance is also included, and the observations recorded show that in at least one plant (*Jasmine*) the water content does not vary appreciably in the transpiring leaf. It is concluded that the limit set to the daily maxima of water loss is due to the rate of water supply to the evaporating surface. A discussion is also included of the general use of relative transpiration as a measure of the physiological change in the transpiring capacity of the leaf.

Internal fissures of *Hevea* cortex, H. SUTCLIFFE (*Rubber Res. Inst. Malaya, Quart. Jour.*, 2 (1930), No. 1, pp. 12-15, pls. 8).—An account is given of the formation of internal fissures in *Hevea* cortex. These have been previously found in *Hevea* trees in West Java but not in Malaya. It is suggested that the formation is due to a differential growth rate between hard and soft bast.

Growth inhibition of potatoes by a volatile substance from apples (*Kansas Sta. Bien. Rpt. 1931-32*, p. 88).—The discovery of an inhibitory substance in apple, pear, and hawthorne fruits is noted.

The *Penicillia*, C. THOM (*Baltimore: Williams & Wilkins Co.*, 1930, pp. XIII+644, figs. 99).—"At best, it is possible to present only a very unsatisfactory scheme of classification of this difficult group. In his first scheme of study [*E.S.R.*, 22, p. 531] the author attempted to follow the lines set by bacteriology in proposing to separate species upon the presence, absence, or intensity of selected biochemical reactions." This scheme, while useful in helping to fix upon fairly broad groups, was not completely satisfactory for separation within related series. The further development of plan and method for the grouping of members of the *Aspergillus* group is indicated. "Some 600 names have been found applied to *Penicillia* and related organisms. . . . To lay a foundation for a permanent knowledge of this lot of molds, the whole range of morphology and physiology must be searched for marks of separation stable enough and sharply enough marked to convey to the reader a definite picture of the organisms studied. Then organism by organism they must be fitted into the scheme of classification to form a consistent and interpretable whole."

GENETICS

The mechanism of creative evolution, O. C. HURST (*New York: Macmillan Co.; Cambridge, Eng.; Univ. Press, 1932, pp. XXI+365, pl. 1, figs. 199*).—Genetic theories are outlined and described, followed by a discussion of creative evolution, in which organisms show a gradual growth in complexity resulting from an increased complexity of the gene make-up brought about by additional mutations and transmutations of genes and chromosomes.

The part played by recurrent mutation in evolution, J. B. S. HALDANE (*Amer. Nat.*, 67 (1933), No. 708, pp. 5-19).—The evolutionary effects of mutation are discussed with reference to evolution due to a mutation rate so large as to cause the spread of a disadvantageous character, primary effects of the spread of genes nearly neutral from the point of view of natural selection, and secondary effects of frequent disadvantageous mutations. It is concluded that mutations provide the material for selection to act upon, and may give rise to primary and secondary effects by accumulation of mutant genes and by protection against lethal genes. These may account for the disappearance of useless organs and the fact that the heterogametic sex is usually male.

Chromosomes in *Gossypium* and related genera, A. E. LONGLEY (*Jour. Agr. Res. [U.S.]*, 46 (1933), No. 3, pp. 217-227, figs. 5).—Cytological studies by the author and by other investigators (*E.S.R.*, 52, p. 823; 61, p. 629) show *Gossypium* species to be characterized by the haploid numbers 13 in the Asiatic group and 26 in the American group. Two wild species *G. davidsoni* and *G. harknessi*, indigenous to North America, *G. sturtii* of Australia, and *Thurberia thespesioides* and *Shantzia garckeana*, closely allied to *Gossypium*, also belong to the Asiatic group. The distribution of the 13-chromosome forms suggests that the ancestors of our American forms of cultivated cottons belonged to the low-chromosome group. The chromosome behavior during meiosis of pollen mother cells of species and most hybrids between forms with the same chromosome number is regular. Marked irregularities are prevalent in a few plants derived from crossing species with the same chromosome number and are universal in an F_1 hybrid between forms with different chromosome numbers.

Inheritance studies in barley [trans. title], A. P. LUNDEN (*Meld. Norges Landbr. Høiskole*, 11 (1931), No. 3, pp. 143-168; *Eng. abs.*, pp. 165-167).—The inheritance of rachilla hairs, awn, internode length, and straw length was studied in Asplund \times D.S. 295 and Holleby \times Smooth Awn. All were 6-rowed barleys, Asplund having short rachilla hairs, rough awns, short internodes, and D.S. 295 having long hairs, smooth awns, and long internodes. Holleby differed from Smooth Awn in the first characters, having short bearded rachilla and rough awns.

Long rachilla hairs were dominant to short and rough awns dominant to smooth, both pairs being inherited on a single factor basis. The factor for awning was identical with the *Rr* factor of other investigators. The *Ss* factor for awning could not be recognized in these crosses. The inheritance of internode length in Asplund \times D.S. 295 depended on two factors, *Aa* and *Ad*, which segregated independently. F_1 , F_2 , and F_3 were intermediate in internode length. In F_2 , constant plants of the parent types, as well as of two intermediate types, were recovered. These intermediates differed in internode length in the lowest part of the spike. No correlation was observed between internode length and straw length in Asplund and D.S. 295, or in their hybrids. Although *Aa* and *Ad*, factors for internode length, did not appear to be linked with *Ll* for long v. short rachilla hairs or *Rr* for rough v. smooth awn, *Ll* and *Rr* were linked with a crossover percentage of 29.4.

Inheritance of resistance to bunt, *Tilletia tritici* (Bjerk.) Winter, and other characters in certain crosses of "Florence" wheat, J. G. CHURCHWARD (*Linn. Soc. N.S. Wales, Proc.*, 57 (1932), pt. 3-4, pp. 133-147, figs. 4).—Studies into F_2 indicated a single factor difference with dominance of susceptibility to bunt in crosses between Florence, a resistant wheat, and each of the susceptible varieties Fribank, Gullen, Yandilla King, and Marshall No. 3. The ratios of 13 normal : 3 dwarfs in 3 of the crosses indicated the action of an inhibiting factor, while in Florence \times Yandilla King the F_2 ratio approximated 55:9, and F_3 results confirmed the assumption of a dominant inhibiting factor and 2 dominant factors for dwarfness. In Gullen \times Florence, and Hard Federation \times Florence, a single factor determined the inheritance of chaff color, which was independent of bunt resistance.

Inheritance in *Nicotiana tabacum*.—VIII, Cytological features of *purpurea* haploid, R. H. CHIPMAN and T. H. GOODSPEED (*Calif. Univ. Pubs. Bot.*, 11 (1927), No. 8, pp. 141-158, figs. 3).—The eighth number of this series (E.S.R., 56, p. 631) gives a detailed description of the cytological behavior of a *N. tabacum purpurea* haploid (E.S.R., 51, p. 827).

Inheritance in *Nicotiana tabacum*.—IX, Mutations following treatment with X-rays and radium, T. H. GOODSPEED (*Calif. Univ. Pubs. Bot.*, 11 (1930), No. 16, pp. 285-298, figs. 4).—Three recessive monogenic mutations induced by treatment of *N. tabacum purpurea* with X-rays and radium, described as to genetic and cytological characteristics, involve pink flower color, pistillody of the androecium, and albino seedlings.

Inheritance in *Nicotiana tabacum*.—X, Carmine-coral variegation, R. E. CLAUSEN (*Cytologia*, 1 (1930), No. 4, pp. 358-368, figs. 9).—The recessive type coral, a derivative of fluted, is shown to have arisen by a modification of the F chromosome (F-co). The origin of a carmine-coral variegated type from fluted \times coral is described. It is shown to depend upon the presence of a fragment of the F chromosome (f-co) containing the factor or factor complex for carmine as opposed to the coral.

Inheritance in *Nicotiana tabacum*.—XI, The fluted assemblage, R. E. CLAUSEN (*Amer. Nat.*, 65 (1931), No. 699, pp. 316-331).—When selfed, fluted (E.S.R., 56, p. 631) produced as further variants the distinctive recessive types coral and mammoth, both established in pure lines and due to secondary modification of the F chromosome. Coral and mammoth crossed with normal or with each other produced hybrids of the normal type which, however, exhibit frequent nonconjunction of the F chromosomes. By reason of this nonconjunction, F_2 and other derivative populations from these crosses contain some haplo-F and triplo-F individuals besides the expected classes of offspring. Hybrids of coral with mammoth apparently exhibit no crossing over between the two modified F chromosomes. Other forms observed in the course of the investigation were pale sterile, carmine-coral variegation, and reversionary self-carmine. It appeared that coral must represent some modification of the F chromosome more extensive than simple factor mutation. The F chromosome in the univalent condition seemed subject to some forms of genetic modification which occur rarely, if at all, in normal material.

Studies in Indian pulses: A note on the cytology of "Kabuli" and "Desi" gram types, P. D. DIXIT (*Indian Jour. Agr. Sci.*, 2 (1932), No. 4, pp. 385-390, pls. 3).—The white large-seeded gram (*Cicer kabulum*) was observed to have 16 as its diploid chromosome number instead of the 14 observed in ordinary cultivated forms of *C. arctinum*. A mutational origin of Kabuli gram from white small-seeded varieties was indicated.

Studies in Indian pulses: A case of gigantism in gram (*Cicer arietinum*), P. D. DIXIT (*Indian Jour. Agr. Sci.*, 2 (1932), No. 4, pp. 391-408, pls. 5).—A giant mutant appearing in gram type 22 at Pusa was characterized by enormous increase in size of plants and all organs compared with the parent, and its diploid chromosome number was 16 v. 14 in the parent.

Genetics of the soybean, C. M. WOODWORTH (*Jour. Amer. Soc. Agron.*, 25 (1933), No. 1, pp. 36-51, figs. 7).—Progress to date in the genetic analysis of the soybean is shown by a list of genes in soybeans, and a chromosome map. Another and more detailed discussion of soybean genetics (E.S.R., 68, p. 463) also described attempts to analyze seed yield into simpler components and genetic correlations among the several components and yields.

The inheritance of several new characters is described from recent studies at the Illinois Experiment Station. Bloom on the seed coat appeared due to three complementary genes, B_1 , B_2 , and B_3 , all of which must be present for its expression. Variegated leaf (v_1) was found to be a simple recessive to normal (V_1) and determinate pod-bearing habit (dt) a simple recessive to indeterminate habit (Dt). Softness of seed coat, i.e., ability to imbibe water readily, appeared to be partly dominant in the F_1 to hardness, and wide variation occurred in F_2 , a few segregates even transcending parental limits. A relation of seed color was indicated with the color genes, R_2T appearing to be involved. In three crosses showing hybrid vigor, one variety was a common parent in two.

Hybridization in *Trifolium pratense* [trans. title], F. E. NIJDAM (*Genetica* [s. Gravenhage], 14 (1932), No. 3-4, pp. 161-278, figs. 29).—Systematic crossing was carried on with 3 F_2 generations of a pair of unrelated P_1 red clover plants, 8 sister plants of each generation being crossed in all possible combinations. Two of the F_2 groups consisted of 2 intra-incompatible but inter-compatible groups, and the third F_2 comprised 4 groups. Systematic crosses between 15 sister plants of an F_2 generation from unrelated ancestors showed again 2 intra-incompatible and inter-compatible groups.

Plants were produced with pure yellow and with pure violet seeds. Crosses between similar plants gave a constant offspring. An F_1 generation uniform in seed color could not be obtained by crossing yellow and violet. The F_2 generation of these crosses segregated into all transitions from yellow to violet in seed color. Back-crossing an F_1 plant with one having pure violet seeds produced only plants with very dark violet seeds, while back-crossing with a plant having pure yellow seeds produced a segregating offspring largely with light colored seed. The number of plants with pure yellow seeds in these groups led in one case to the suggestion of 5 factors for violet tingeing in F_1 . A certain amplitude of variation in color seemed to exist in plants having seeds of more than one color, the distribution being controlled practically by the genetic constitution. The effect of a single factor V , for violet, and possibly of X , for intensifying color, was evident in certain groups selected for yellow seed. Variation in the shade of yellow seemed to be controlled by C . The shade of violet changed from red to violet and purple blue due to R .

Plants with white flowers seemed to lack the factor G for anthocyanin production. In the flowers, series of purple and flesh-pink tints could be distinguished. Purple was dominant, but plants heterozygous for the purple factor B might often be distinguished easily from the homozygotes. Purple modifying factors did not affect pink color. In a few segregations 3 factors seemed to affect the intensity of purple. Normal green leaf color became yellowish green in the absence of N . Examples of albinism were also noted.

Sterile stamens were found due to a factor P . A factor D appeared necessary for normal development, whereas dd plants showed a typical dwarf habit

and were only a few centimeters in height. This dwarf variety also had many morphological and anatomical differences from normal. Constant specimens of a type with little growth, short branches, often abnormal leaves, and poor flowering were recessive to normal. The F₂ showed irregular monohybrid segregation.

The bibliography lists 72 titles.

Studies in animal reproduction and inheritance (Kansas Sta. Bien. Rpt. 1931-32, pp. 82-84).—Modifiers for red color, long hair, a nervous character called "trembling", and sex in guinea pigs are reported. Findings are also given on the inheritance of eye defects, bad temper, and wry neck in rabbits and the inheritance of color in cattle, all by H. L. Ibsen, and the location of a lethal factor in *Apotettix eurycephalus* and the influence of X-rays and violet and white light on chromosome behavior and the reproductive cycle in the grouse locust, by R. K. Nabours.

Dominant vs. non-dominant genes in the multiple factor hypothesis of size inheritance, H. D. GOODALE (*Jour. Heredity*, 23 (1932), No. 12, pp. 487-498, fig. 1).—The author discusses the consequences of the multiple factor hypothesis, and points out the conditions that must be complied with in cases of nondominant genes and the failure in a number of cases cited from the literature of the F₂s to be halfway between the parent races in size. Genotypic and phenotypic ratios expected under different conditions are tabulated. From various tests it is suggested that the current explanation of size inheritance by means of nondominant genes is not adequate to explain the observations, but that many may be explained by the existence of dominant genes in various degrees of heterozygosity.

Genetical evidence for a cytological abnormality in man, J. B. S. HALLDANE (*Jour. Genetics*, 26 (1932), No. 3, pp. 341-344).—Six human pedigrees showing abnormal inheritance have been selected from the literature, which the author explains on the basis of nondisjunction of the sex chromosomes, suggesting that the women were XXY.

Milk goat improvement (*New Mexico Sta. Rpt. 1932*, p. 55).—An account is given of inbreeding and the inheritance of a character described as double teat.

A report on the progeny of a tortoise-shell male cat, together with a discussion of his gametic constitution, R. C. BAMBER (BISBEE) and E. C. HERDMAN (*Jour. Genetics*, 26 (1932), No. 1, pp. 115-128).—In breeding studies a male tortoise-shell cat was found to give the progeny expected of a yellow male with one exception. In matings with black females there were produced 13 black males, 14 tortoise-shell females, and 1 black female. When mated with yellow females the offspring were 9 yellow males, 8 yellow females, and 1 anomalous yellow male. In matings with tortoise-shell females there were produced 1 black male, 1 yellow male, 5 yellow females, 2 tortoise-shell females, and 1 anomalous yellow female. The expected results were approximately obtained in matings of the tortoise-shell and yellow daughters with black and yellow males.

Various theories advanced to explain the occurrence of tortoise-shell males are discussed, and it is concluded that nondisjunction of the yellow part of the black-bearing sex chromosome in the mother of the male best explains the results.

On the morphogenetic relation of body weight in the newborn to organ and bone weight in the mature mouse [trans. title], S. KOPÉĆ and M. LATYSZEWSKI (*Ztschr. Induktive Abstam. u. Vererbungslehre*, 63 (1932), No. 3, pp. 185-194).—Determinations were made at 253 days of age in the 81 male

and 78 female mice referred to in the preceding abstract. Comparison of the size of the organs and bones in the mice born in litters of from 5 to 9 and those born in litters of from 10 to 13 revealed practically no significance in the differences observed. In contrast, significant differences were observed in the bones and the weights of certain organs from the mice grouped as to those which were above and below the average weight for the individuals in the litters at birth.

Investigation of the morphogenetic relation of birth weight to body weight in the mouse [trans. title], S. KOPEĆ (*Ztschr. Induktive Abstam. u. Vererbungslehre*, 63 (1932), No. 1-2, pp. 94-111, figs. 4).—Comparison is made of the mature weights and birth weights of 81 male and 78 female mice born in two litter sizes, i.e., 5-9 and 10-13. These results indicate that the differences in birth weights are reliable indicators of mature weight differences.

Hydrocephalus, a hereditary character in the house mouse, F. H. CLARK (*Natl. Acad. Sci. Proc.*, 18 (1932), No. 11, pp. 654-656, fig. 1).—An account is given of the occurrence of hydrocephalic offspring in the F_2 and back-cross generations of mice involving the flexed-tail character. Hydrocephalus was evidently inherited as a single Mendelian factor, the recessive being lethal. Its frequent association with flexed tail suggests the possibility of linkage, or that the two characters are manifestations of the same gene.

A hairless mutation in the rat, W. WILDER, R. M. BETHKE, C. H. KICK, and W. P. SPENCER (*Jour. Heredity*, 23 (1932), No. 12, pp. 480-484, figs. 3).—An account is given of the occurrence of a hairless mutation in the rat colony of the Ohio Experiment Station. In breeding tests it appeared to be recessive to the normal. Matings of heterozygotes produced 140 normal and 45 hairless offspring, and in back-cross matings there were produced 21 normals and 17 hairless young. Hairless females were usually sterile. Hairless males tended to regenerate more hair than females during the wave of hair regeneration about the third or fourth month. The hairless character was not linked to albinism.

Cytogenetic studies on the rat. Somatic chromosome complex, meiosis, and chiasma frequency, W. BRYDEN (*Jour. Genetics*, 26 (1932), No. 3, pp. 395-415, figs. 17).—The behavior of the 42 chromosomes in the cell division in male and female rats from 3 weeks to 9 months of age is described from the University of Edinburgh. Special attention is given to chiasma frequency and its relation to crossing over. The number of chiasmata per bivalent observed in the male was found to decrease with advancing stages of mitosis from 1.91 in the early diplotene to 1.56 in the metaphase. The mean number of chiasmata in females is 1.98, and in males 1.56. The greater frequency of chiasmata in females corresponds with the findings of larger amounts of crossing over in females. The observations suggest that crossing over takes place in the early prophase stages and that the chiasmata are the result of crossing over.

Differences in bactericidal power of the blood within an inbred strain of rats, M. R. IRWIN and T. P. HUGHES (*Soc. Expt. Biol. and Med. Proc.*, 29 (1931), No. 3, pp. 295-297).—The ability of the blood of inbred rats to destroy *Streptococcus enteritidis* organisms was tested by the incubation of cultures with samples of blood and determination of the number of living organisms at the end of four hours. Individual rats showed marked differences in the bactericidal power of the blood. Matings of animals in which the blood showed low bactericidal power produced 11 young also classed as low, whereas matings of individuals classed as high with others classed as low produced 18 offspring in which the power of the blood to destroy *S. enteritidis* organisms was classed as low in 12 and high in 6.

Blood group inheritance in the rabbit, W. E. CASTLE and C. E. KEELER (*Natl. Acad. Sci. Proc.*, 19 (1933), No. 1, pp. 92-98).—The occurrence of two agglutinogens in the blood of rabbits is noted, together with inheritance studies of them. The genes for both were dominant to their absence. In matings involving these characteristics, it was found that they were either due to different allelomorphs of the same gene or closely linked. The occurrence of four h_1h_2 and two H_1H_2 individuals in 308 offspring from a mating of h_1h_2 and H_1H_2 parents and two h_1h_2 young among 154 from a mating of h_1H_1 and H_1H_2 parents are attributed to imperfect technic.

Tests for linkage between the blood-group genes and other known genes of the rabbit, W. E. CASTLE and C. E. KEELER (*Natl. Acad. Sci. Proc.*, 19 (1933), No. 1, pp. 98-100).—The results of tests of the linkage relations between the genes for the hemagglutinogens described in the above paper, and the genes for agouti, intense pigmentation, extended black pigmentation, English spotting, and rex coat are reported, with negative results as far as linkage is concerned. The deviations from independent inheritance were in all cases less than twice their probable errors.

[**Breeding experiments with poultry at the Kansas Station**], D. C. WARREN (*Kansas Sta. Bien. Rpt.* 1931-32, pp. 72-74, 81, 82).—Findings are reported as to the inheritance of crookedness of the keel bone, distinguishing the sex at hatching of Single Comb Rhode Island Red chicks on the basis of rate of feather development, linkage relationships between breed characteristics, inheritance of egg production in Single Comb Rhode Island Red chickens, and influence of hybridization upon vigor in poultry.

Inheritance of spangling in the domestic fowl, L. W. TAYLOR (*Jour. Genetics*, 26 (1932), No. 3, pp. 385-394, pls. 3).—From studies at the University of California of crosses between Silver Spangled Hamburg, Rhode Island Red, and Black Minorca fowls, it is concluded that spangling is due to a dominant autosomal gene which is incompletely dominant in the absence of extension factors for black. The expression of spangling is complicated by limitations in the expression of black and the sex-linked gold factors. The action of the female sex hormone is used to explain the greater development of black pigment in females than in males.

The suggested composition of the three breeds for spangling and extended black is Rhode Island Reds, $ReRe E^mE^m spsp$; Black Minorca, $rerc E^mE^m spsp$; and Silver Spangled Hamburg, $rere e^me^m SpSp$; in which Re is the dominant gene for nonextension of black, E^m is dominant for extension of black, and Sp is dominant for spangling.

The chromosomes of the domestic chicken, M. J. D. WHITE (*Jour. Genetics*, 26 (1932), No. 3, pp. 345-350, pls. 4).—Studies of the chromosomes in somatic tissue of fowl embryos, conducted at the University College, London, showed that the diploid number is approximately 66 in males and 65 in females. There is great variation in the size of the chromosomes, but the sex chromosomes are the largest. The W chromosome was not found in females.

Studies on the creeper fowl.—II, Morphology and histology of the skeleton, especially the long bones [trans. title], W. LANDAUER (*Ztschr. Mikros. Anat. Forsch.*, 25 (1931), pp. 115-180, figs. 36; *Eng. abs.*, pp. 175-178).—Continuing this series (*E.S.R.*, 65, p. 425), the morphology and histology of the skeleton of embryonic, growing, and adult creeper fowls are described as compared with the conditions found in chondrodystrophy in humans.

Studies on the creeper fowl.—IV, The abnormal development of homozygous creeper embryos in the later stages of development (phoko-

melia and chondrodystrophy) [trans. title], W. LANDAUER (*Ztschr. Mikros. Anat. Forsch.*, 32 (1933), No. 3, pp. 359-412, figs. 27; *Eng. abs.*, pp. 408-411).—In this continuation of the series (E.S.R., 68, p. 606) detailed descriptions are given of homozygous creeper embryos which survived the normal lethal date, from the third to the fourth day of incubation, but died between the tenth and twenty-second day of incubation.

Descriptions are included of the anatomical and histological studies, particularly of the skeletal parts and the eye. The weights of the creeper fowls were materially reduced as compared with normals, and the shortening of the long bones and the malformation of the skull were pronounced.

It is suggested that the creeper gene is probably a sectional deficiency of the chromosome.

Studies on the creeper fowl.—V, The linkage of the genes for creeper and single-comb, W. LANDAUER (*Jour. Genetics*, 26 (1932), No. 2, pp. 285-290).—Continuing this series of studies (see above), F₁ rose-comb creeper fowls were produced by mating the four lines of creeper fowls from Scotland, Germany, America, and the Marquesas Islands with normal rose-comb birds. These diheterozygous F₁s were back-crossed in reciprocal matings with Single Comb White Leghorns, and a very close linkage between the creeper and single-comb genes was found. Among the 6,627 back-cross individuals obtained there were only 25 crossovers. The crossover percentage in females was 0.57 percent, and in males 0.13 percent. All four creeper lines appeared to be due to an identical mutation.

Chondrodystrophy in fowl embryos, S. S. MUNRO (*Sci. Agr.*, 13 (1932), No. 2, pp. 97-109, figs. 6).—Chondrodystrophy was found to cause about 8 percent of the embryonic deaths occurring after the seventh day during the early part of the hatching season. The frequency of occurrence of this condition declined as the season advanced. Sunlight is suggested as an important etiological factor, but something other than vitamin D appears to be responsible. Although this condition seems to have some hereditary basis it is not a simple recessive.

In the rhesus monkey ovulation is spontaneous, G. W. CORNER (*Soc. Expt. Biol. and Med. Proc.*, 29 (1932), No. 5, pp. 598, 599).—Four female monkeys kept in separate cages showed recent corpora lutea in their ovaries, indicating the occurrence of spontaneous ovulation in this species without copulation.

Maturity in the female mouse, L. MIRSKAIA and F. A. E. CREW (*Roy. Soc. Edinb. Proc.*, 50 (1929-30), No. 2, pp. 179-186, fig. 1).—The attainment of sexual maturity was studied in 58 colored and 42 albino female mice. It was found that there were considerable individual differences between the stocks in this respect as well as in other breeding and reproduction characteristics, making it necessary for each worker to standardize his own stock and his own environment.

On the presence of a kyogenic substance in the mouse placenta, L. MIRSKAIA (*Roy. Soc. Edinb. Proc.*, 50 (1929-30), No. 1, pp. 104-112, pl. 1).—It was demonstrated by implantations of mouse placenta into immature female mice that the placenta contained an active kyogenic substance, since the following conditions were produced: Characteristics of pregnancy in the vaginal epithelium, growth of the follicles in the ovary, and enlargement of the interstitial tissue.

The effect on lactating mice of injecting an extract of the urine of pregnancy, E. V. ENZMANN and G. PINCUS (*Amer. Jour. Physiol.*, 103 (1933), No. 1, pp. 30-33, figs. 8).—Extracts of pregnancy urine had a deleterious effect on lactating mice, as measured by the rate of growth and mortality of the young.

Effects produced by intravenous and intraperitoneal injections of urine of pregnancy in immature female rabbits, J. M. WOLFE and E. T. ELLISON (*Soc. Expt. Biol. and Med. Proc.*, 29 (1932), No. 5, pp. 600, 601).—A comparison of the effects produced by intraperitoneal and intravenous administration of pregnancy urine to immature female rabbits showed very different results. Intravenous injections stimulated follicles having well-developed cavities, but did not act on the smaller and more primitive follicles. On autopsy the ovaries of animals which had received intraperitoneal injections contained a large number of small blood follicles with marked luteinization of most of them.

Specificity in action of anterior pituitary of different mammals and urine of pregnant women on ovary and thyroid, L. LOEB (*Soc. Expt. Biol. and Med. Proc.*, 29 (1932), No. 5, pp. 642-644).—A summary is given of the effects of the administration of the anterior pituitary from cattle, male guinea pigs, rabbits, and cats, and the urine of pregnant women on the ovaries and thyroid glands of immature guinea pigs. Differences in the action of the pituitary substances from different sources are noted. The tendency to cause hypertrophy in the thyroid glands was related to the ability of these substances to produce interstitial glands and pseudolutein tissue in the ovary, but seemed independent of their ability to accelerate follicle maturation and to produce ovulation. The urine of pregnant women caused a marked production of interstitial gland and pseudolutein tissue without causing thyroid gland hypertrophy, suggesting that the active substance in urine differs from the active substance in the anterior lobe of the pituitary.

The gonadotrope actions of the anterior lobe of the pituitary, B. P. WIESNER and F. A. E. CREW (*Roy. Soc. Edinb. Proc.*, 50 (1929-30), No. 1, pp. 79-103, pls. 2).—From studies of the effects of administering the oestrogenic hormone and the implantation of pituitary substance on sexual maturity, it is suggested that there are two gonadotrope factors as well as a growth factor produced by the anterior lobe of the hypophysis.

Volume of the various lobes of the hypophysis during pregnancy in the rat, S. STEIN (*Soc. Expt. Biol. and Med. Proc.*, 29 (1931), No. 3, pp. 282, 283).—Hypophyses removed from pregnant and nonpregnant female rats at approximately 185 g live weight were found to show no significant differences in weight. The relative volume of the lobes was also similar. Other groups from which the hypophyses were compared included animals which had received vitamin E-deficient rations.

The induction of precocious sexual maturity by cortico-adrenal extract, E. L. COREY and S. W. BRITTON (*Amer. Jour. Physiol.*, 99 (1931), No. 1, pp. 33-43, figs. 16).—Injections of cortico-adrenal extract into 63 immature experimental rats caused enlargement of the pituitary gland, premature maturation of the sex glands particularly in the females, and uterine hypertrophy. The development of the pituitary gland was the only change observed in the rats at 20 days of age, but at 28 days the ovaries exhibited corpora lutea and uterine hypertrophy was noted. Histological changes in the testes were first observed at 35 days of age. No significant differences were observed between the thyroid glands of the experimental animals and those of controls injected with adrenalin.

Precocious development of sexual characters in the fowl by homeoplastic hypophyseal implants, I, II, L. V. DOMM (*Soc. Expt. Biol. and Med. Proc.*, 29 (1931), No. 3, pp. 308-312).—Two papers in this series are presented.

I. The male (pp. 308, 309).—The daily subcutaneous implantation over a period of from 19 to 28 days of homeoplastic whole or anterior lobe hypophyseal grafts into Brown Leghorn cockerels from 22 to 86 days of age induced a

marked increase in the development of the comb, precocious sexual behavior, hypertrophy of the testes, and advanced spermatogenesis. No significant modifications were observed in the plumage, spurs, or other organs. Hypophyses obtained from capons were most effective, from cocks next, and from hens least, when employed as the material for the grafts.

II. *The female* (pp. 310-312).—Daily subcutaneous homeoplastic implants of the anterior lobe of the hypophysis were administered for from 19 to 28 days to female Brown Leghorns ranging from 28 to 59 days of age. The grafts stimulated the growth of the head furnishings, especially the comb, and increased the size of the ovaries and other sex glands, and advanced development was shown in histological study of a number of the sex glands. There was no noticeable change in the plumage, spurs, behavior, or histological picture of the ovary. It was believed that the gonad-stimulating hormone of the hypophyseal implants produced a precocious endocrine rather than gametogenetic functioning, which was responsible for the precocious development of other sex characters. The growth of the head furnishings and rudimentary Wolffian ducts in the male resulted from liberation of the male hormone by the stimulated medullary tissue. The female hormone was liberated by the stimulated cortical tissue, and was responsible for the development of the oviduct.

Injection of avian anterior pituitary substance into the Leghorn fowl, J. B. MITCHELL, JR. (*Soc. Expt. Biol. and Med. Proc.*, 29 (1932), No. 5, pp. 645, 646).—In three experiments daily intramuscular injections of anterior lobes of chicken hypophyses were administered to White Leghorn pullets in doses up to 10 lobes for 56 days. There was no response of the female genital system to the pituitary substance.

Purification of corporin, H. L. FEVOLD and F. L. HISAW (*Soc. Expt. Biol. and Med. Proc.*, 29 (1932), No. 5, pp. 620, 621).—The preparation of a crystalline substance with a high corporin potency is described. The uteri of rabbits showing pronounced progestational changes from treatment with the crystalline preparation continued to give a strong response to pituitrin in direct contrast with those which had received crude corporin preparations.

Administration of theelol to the immature Brown Leghorn female, J. B. MITCHELL, JR. (*Soc. Expt. Biol. and Med. Proc.*, 29 (1932), No. 5, p. 644).—The administration of varying doses of theelol to three lots of 5-months-old Brown Leghorn pullets for 96 days caused no inhibition nor stimulation of ovulation.

Does castration in guinea fowls produce sexual differentiation in plumage and changes in head furnishings? J. KRÍŽENECKÝ and L. F. KAMENÍČEK (*Soc. Expt. Biol. and Med. Proc.*, 29 (1932), No. 5, pp. 653, 655).—This is another account of the studies previously noted (E.S.R., 68, p. 318).

FIELD CROPS

Variation of yields obtained in small artificially constructed field plats, R. J. GARRER and W. H. PIERRE (*Jour. Amer. Soc. Agron.*, 25 (1933), No. 2, pp. 98-105).—Study of the variation of the yields of wheat, soybean hay, and Sudan hay, obtained at the West Virginia Experiment Station during three years from 30 concrete soil bins, each 0.001 acre in area, indicated that soil heterogeneity, insofar as it influences yield over a period of years, may largely be removed by mixing the soil thoroughly. However, the uniformity crops of wheat and soybean hay showed that the variance between plats in any one year is still too high to obviate replication. The probable error of a single determination in percentage of the mean for the yield of soybean hay per plat was 3.4, and for the yield of wheat grain plus straw (also for grain alone)

per plat was 6.2, whereas the probable error of a single determination in percentage for the total yield of soybeans and wheat (grain plus straw) per plat was only 2.5 percent.

Examination of the variation of yields of alfalfa obtained from 42 soil bins made with 24-in. sewer tile showed that the height to which soil is filled in the tile may influence markedly the first yields of alfalfa. The correlation coefficient measuring this relation was found to be 0.668. Later yields of alfalfa did not seem to be affected. The probable error of a single determination expressed as a percentage of the mean of total yields of alfalfa grown during one year in triplicated tile plats was found to be 6.74.

[Experiments with field crops in Florida] (*Florida Sta. Rpt. 1932, pp. 28-49, 50, 63, 112-118, 152-156, 180-184, 205-207, 208-212, 217, 218, figs. 6*).—Agronomic investigations (E.S.R., 67, p. 516), by W. E. Stokes, J. P. Camp, J. D. Warner, F. H. Hull, G. E. Ritchey, W. A. Leukel, A. Daane, R. W. Kidder, R. W. Ruprecht, M. R. Ensign, W. A. Carver, L. O. Gratz, R. R. Kincaid, R. M. Crown, B. A. Bourne, and F. D. Stevens, again reported on from the station and substations, comprised breeding work with corn, sweet corn, cotton, peanuts, and sugarcane; induction of mutations by heating seed corn; variety trials with corn, sweet corn, cotton, sorgo, grain sorghum, sugarcane, millet, peanuts, *Crotalaria* for hay, miscellaneous forage, pasture, and lawn grasses, legumes, and winter cover crops; variety-date-of-planting tests with cowpeas and soybeans; fertilizer tests with corn, oats, cotton, peanuts, sugarcane, potatoes, Austrian winter peas, vetch, and tobacco; date-of-planting and turning under winter legumes for corn and their phosphorus needs; soil amendment studies with peanuts; cultural (including planting) trials with corn, cotton, potatoes, and peanuts; a photoperiodism experiment, a comparison of mechanical pruning v. freezing, and a paper mulch test with potatoes; germination studies with tobacco seed; and crop rotations using winter legumes. Pasture investigations were concerned with competition, carrying capacity, effects of fertilizers and frequency of cutting on yield and composition of grasses; fertilizer, lysimeter, and growth behavior studies with pasture grasses; the growth behavior of and influence of different fertilizer formulas on yields of Bahia grass; and pasture studies on peat and muck soils. Several phases of the work were in cooperation with the U.S. Department of Agriculture.

[Field crops work in Georgia, 1932] (*Georgia Sta. Rpt. 1932, pp. 12-25, 37, 49, figs. 3*).—Agronomic activities (E.S.R., 66, p. 729) again reviewed briefly comprised breeding work with oats, wheat, and soybeans; studies of wheat-rye hybrids (E.S.R., 67, p. 513); variety trials of soybeans for seed and hay; variety-time-of-planting tests with cotton; development of one-variety cotton centers; effects of time and method of planting on germination of cottonseed, and of low temperature and early planting on the germination of seed of cotton varieties; fertilizer studies with cotton dealing with placement, addition of dolomitic limestone where acid-forming nitrogen carriers are used, supplements for concentrated fertilizer, nitrogen carriers, and comparisons of ammoniated superphosphate and other phosphorus carriers, with and without gypsum and limestone supplements; comparison of ammonium and nitrate nitrogen for cotton plants in water cultures; fertilizer tests with cowpeas, vetch, and Austrian winter peas; and fertilizer trials with sweetpotatoes and corn and spacing tests with sweetpotatoes at the Mountain Substation. Certain phases of the work were in cooperation with the U.S. Department of Agriculture.

[Field crops research in Kansas, 1930-32] (*Kansas Sta. Bien. Rpt. 1931-32, pp. 30-32, 33-45, 47-50, 117-119, 121-123, 124, 125, 126*).—Agronomic experiments (E.S.R., 64, pp. 826, 835) reported on again from the station and

substations included variety tests with winter and spring wheat, corn, pop corn, oats, barley, grain sorghum, sorgo, flax, potatoes, soybeans, red clover, alfalfa for yield, winter hardiness, and wilt resistance, sweetclover, bentgrass for lawns, and miscellaneous grasses and legumes; breeding work with corn, pop corn, wheat, oats, barley, grain sorghum, soybeans, alfalfa, and sweetclover; cultural (including planting) experiments with corn, wheat, barley, grain sorghum, sorgo, soybeans, alfalfa, and buffalo grass; comparison of seed bed preparations for wheat, flax, Sudan grass, and sweetclover; harvesting tests with soybeans; effect of moisture content on keeping quality of grain sorghum; cold resistance studies with wheat and alfalfa varieties; seed treatments for corn; fertilizer trials with wheat and alfalfa; liming tests with sweetclover; studies of wheat quality as influenced by seed bed preparation, variety, and heritable factors; chemical and tempering factors affecting the quality of flour; a study of gluten proteins, crude fiber, and other factors thought to influence gluten quality; fertilized, irrigated, and ordinary crop rotations; irrigation requirements of alfalfa, sugar beets, grain sorghum, and sorgo; pasture improvement work including management of livestock and effect of burning on bluestem pastures, eradication of undesirable plants, effects of various clippings (simulating grazing), and of fertilizers on yield, vigor, and quality of pastures, and determination of nutritive content and organic food reserves of pasture plants; clipping, watering, and fertilizer tests and weed control on lawns; and control of blindweed, Johnson grass, and narrowleaf plantain by chlorate sprays. Certain lines of work were in cooperation with the U.S. Department of Agriculture.

[Field crops experiments in New Mexico] (*New Mexico Sta. Rpt. 1932*, pp. 15-22, 23, 24, 25-27, 33-37, 52-54, 66-68, 70, 71).—Agronomic investigations (E.S.R., 67, p. 29), reported on from the station and from outlying fields near Clayton, Capulin, and Mosquero, embraced variety tests with winter- and spring-sown wheat, oats, barley, corn, grain, sorghum, sorgo, cotton, alfalfa, soybeans, cowpeas, field beans, millet, and miscellaneous hay crops; breeding work and biometrical (E.S.R., 67, p. 519) and genetic studies with cotton; response of winter wheat to different dates of planting and methods of soil preparation; fertilizer trials with cotton (E.S.R., 67, p. 380) and alfalfa; irrigation and spraying tests with potato varieties; studies of the annual production of sugar beet seed, involving method, rate, and date of planting, and rate of irrigation; breeding for resistance to the curly top disease of sugar beets; investigation of factors affecting growth and germination of chamiza (*Atriplex canescens*), winter fat (*Eurotia lanata*), and *Valota saccharata*; trials of range-plants; adaptation of various grasses and Ladak alfalfa for range improvement; germination tests of seed of range forage plants; determination of the protein and moisture content of samples of New Mexico wheat grown on dry land and under irrigation; and control of Johnson grass by chlorate spray. Several lines of work were in cooperation with the U.S. Department of Agriculture.

[Crops experiments in Rhode Island] (*Rhode Island Sta. Rpt. [1932]*, pp. 47, 48, 49, 51, 55).—Progress is reported on agronomic research including variety tests with bentgrasses for permanence and seed production, silage corn, and peppers; seed source trials with potatoes; breeding work with alfalfa; comparison of sodium nitrate and ammonium sulfate on lawns; effect of fertilizers on seed production of Rhode Island bentgrass; the fertilizer needs of grasses and red clover; a study of methods for measuring growing plants in situ; and methods of eradicating brush in pasture improvement.

[Agronomic studies in England] (*Jour. Natl. Inst. Agr. Bot.*, 3 (1932), No. 2, pp. 142-201).—Research with field crops reported on included variety trials

with spring oats (1931), and mangels and swedes (1929-31), all by W. H. Parker. and with sugar beets (1931), by S. F. Armstrong; tests of the bread-making quality of wheats harvested in 1931, by A. and S. Humphries and L. H. Read; and the Lord Derby Gold Medal potato trials (1931), by W. H. Parker and H. Bryan. The reports of the Potato Synonym Committee for 1931 and 1932, by R. N. Salaman et al., and decisions of the Cereal Synonym Committee on varieties of wheat, oats, and burley are also included.

Crop investigations on peat lands, H. K. HAYES, A. C. ARNY, H. K. WILSON, and L. POWERS (*Minnesota Sta. Bul.* 292 (1932), pp. 32, figs. 3).—Continued experiments on peat lands (E.S.R., 55, p. 527) showed the productive varieties of cereal and seed crops to include Minrus, Iowar, and North Dakota Station selections from Green Russian oats; Pentland and Manchuria barley for grain and Trebi for feed; Rosen, Swedish, and Dakold rye; Redwing flax; Rustler and Minnesota No. 13 corn; Minsoy soybeans; Robust and Brown Swedish field beans; and Golden Vine field peas. Wheat did not appear to be suitable for peat soils. In general, the same varieties are recommended for peat as for mineral soils.

The comparative acre yields and production of digestible nutrients by the several crops are discussed in some detail. Estimated acre values, based on average prices for 1921-30 in the three months of intensive marketing and on oat yields, are for corn, \$22.64; winter rye, \$20.17; flax, \$19.02; winter wheat, \$15.42; barley, \$12.69; oats, \$12.16; durum wheat, \$10.50; and spring wheat, \$8.11.

Crop investigations on sandy lands, H. K. HAYES, A. C. ARNY, H. K. WILSON, and L. POWERS (*Minnesota Sta. Bul.* 291 (1932), pp. 30, figs. 2).—Leading varieties in tests conducted on the Coon Creek Sand Experimental Fields from 1919-32, included Minota oats, Ceres spring wheat, Minturki winter wheat, Swedish rye, Pentland and Trebi (for feed) barleys, Rustler and Minnesota No. 13 corn, Minsoy and Chestnut soybeans, and Robust beans. Field peas for seed and flax appeared undesirable for sandy lands.

The acre yields and production of digestible nutrients by the several crops are compared and discussed. The estimated average acre values were for rye, \$13.14; spring wheat, \$11.45; winter wheat, \$11.01; corn, \$10.92; durum wheat, \$10.59; flax, \$8.95; oats, \$8.32; and barley, \$6.82.

Tillage practices for southwestern Kansas, R. L. VON TREBBA and F. A. WAGNER (*Kansas Sta. Bul.* 262 (1932), pp. 17, figs. 2).—Results of experiments on seed bed preparation for row crops and winter wheat, planting sorghums, and the merits of fallow for row crops, carried on dry land for various periods at Garden City, in cooperation with the U.S. Department of Agriculture, are interpreted for farmers in southwestern Kansas. Methods for the control of soil blowing are indicated briefly. The information has largely been noted earlier (E.S.R., 58, p. 129; 64, p. 826).

The most important method of conserving soil moisture is timely and proper cultivation to suppress weeds. Fall or early spring breaking of the soil for row crops was found preferable to late spring breaking. Planting in furrows of medium depth appeared best for listed row crops. The sorghums produced higher average annual yields when planted with furrow openers on a surface planter than when listed. The data showed that kafir and milo should be planted as near June 1 to 10, and feterita as near June 15 to July 1 as soil and weather conditions will permit, whereas forage sorghums may be planted up to June 15 or 20 and maximum yields obtained. The optimum date for seeding wheat over a period of years was found to be between September 20 and October 10. Compared to the best method of continuous cropping, fallow

increased the average yield of kafir 77 to 92 percent, milo 75 percent, sorgo forage 77 percent, and wheat 87 percent. The authors point out that fallow stabilizes farm incomes by making possible the production of a crop in dry years when crops fail on continuously cropped land.

Corn and soybeans for silage, R. G. WIGGANS (*New York Cornell Sta. Bul.* 548 (1932), pp. 36, figs. 3).—Experiments covering the period 1922–31 included comparisons of corn and soybeans grown alone for silage, of corn v. various combinations of corn and soybeans grown in alternate rows and in the same row, and tests of varieties of soybeans for combination and of the effect of corn on the growth of soybeans. Conclusions based on the results and held applicable to similar conditions may be summarized as follows:

Good soybean varieties, grown alone in cultivated rows at the same spacing as corn, will produce from one half to three fourths as much green weight and from 65 to 80 percent as much dry weight as corn. The fact that soybeans and corn grown alternately in 2-row blocks give from 15 to 20 percent less green weight and from 7 to 15 percent less dry weight than corn grown alone makes this practice of questionable value. About one half this loss occurred with one row of soybeans and 2 rows of corn grown alternately, and the latter method of culture gives a ratio of corn to soybeans approaching very closely that recommended for silage, 3:1. A combination of corn at the optimum rate for silage, one stalk every 9 in. with three times as many soybean plants in the same row, will average significantly more total dry weight than corn alone, and the ratio of corn to soybeans in the silage will approximate the recommended proportion. Any combination of the two crops will reduce the corn yield and the proportion of grain in the corn. The loss of grain in the corn will not be made up by the grain in the soybeans. The effect of soybeans on corn in the combination is somewhat in proportion to the size of the corn, i.e., the smaller the corn the greater is the percentage reduction in corn and the greater the proportion of soybeans. Indications were that any of several varieties of soybeans growing in the same row with a good silage corn will increase the total dry-weight production. The total digestible nutrients produced on a unit area are increased, while the nutritive ratio is materially narrowed by the combination of the crops.

Inoculation of legumes, W. A. ALBRECHT (*Missouri Sta. Bul.* 322 (1933), pp. 8, figs. 4).—Essentially a revision of Bulletin 282 (E.S.R., 63, p. 225).

Some factors affecting the palatability of pasture plants, A. B. BEAUMONT, R. E. STITT, and R. S. SNELL (*Jour. Amer. Soc. Agron.*, 25 (1933), No. 2, pp. 123–128).—When milk cows were allowed to graze selectively over plats of four species of plants grown under differential fertilizer treatments at the Massachusetts Experiment Station, they selected the species in the order of white clover, timothy, redtop, and Kentucky bluegrass. Where eight grasses were grown under uniform fertilizer conditions the order of selection was timothy, redtop, Italian ryegrass, English ryegrass, yellow oatgrass, meadow fescue, red fescue, and reed canary grass, the last two being hardly touched. This order of choice prevailed when the grass was 4 to 6 in. high, while little discrimination was shown when it was 2 to 4 in. high, suggesting that stage of growth is a factor affecting palatability.

In the first year after seeding practically no difference in palatability could be attributed to difference in fertilizer application, but second-year grass which had received nitrogen and minerals was grazed more than that receiving only minerals or no fertilizer. Grass which received high nitrogen appeared to be slightly more palatable than that which received medium or low quantities. When toughness of grasses was determined by breaking or cutting the individual

blades of grass, red fescue and Kentucky bluegrass proved significantly tougher and also less palatable than timothy and reedtop. However, reed canary grass, one of the least palatable, was the least tough.

Barley production in North Dakota. T. E. STOA (*North Dakota Sta. Bul.* 264 (1933), pp. 39, figs. 5).—General information is given on the production of barley in the State, the climatic and cultural requirements of the crop, and on its utilization commercially as food and feed for livestock, its feeding value, and on seed treatment for control of smut. The results of variety tests (E.S.R., 53, p. 232) in the State, in some places in cooperation with the U.S. Department of Agriculture, are reported in some detail, and the results of feeding trials at the station with steers and pigs are summarized. The origins, agronomic characteristics, and behavior are given for 18 of the varieties studied.

Manchuria (N.D. 2121) barley was used as the standard of comparisons. The Manchuria-Oderbrucker type, the oldest and perhaps the most widely grown 6-row barley, is preferred by maltsters. Trebi, since its introduction, has been outstanding in yields, equaling or outyielding Manchuria in numerous field trials. It is not desirable for malting, however, either alone or in mixtures. Velvet, a satisfactory malting barley, and Glabron, less desirable for the purpose, averaged about the same in yield as Manchuria. Two-row barleys, generally later maturing than the 6-row sorts, are not grown to any extent in North Dakota, although giving substantial yields. Hull-less and hooded barleys usually yield so much less than standard hulled awned varieties that they are not recommended unless particularly desired.

Anatomy and microchemistry of the cotton seed. R. G. REEVES and C. C. VALLE (*Bot. Gaz.*, 93 (1932), No. 3, pp. 259-277, figs. 21).—Observations made in the course of studies at the Texas A. and M. College on seed of varieties of American upland cotton, principally Mebane, and on seed of Pima and Sea Island cotton may be summarized as follows:

The seed of cotton is composed of the embryo, endosperm, and perisperm, the inner pigment, palisade (Malpighian), colorless, and outer pigment layers, and the epidermis, including lint hairs. Traces of starch, in addition to oil and protein, occasionally occur in the cells of both young and mature embryos. Substances commonly recognized as pentosans in the hulled seeds are located in the resin glands. Starch, oil, and protein occur within the cells of the endosperm. The cell walls of this tissue and of the embryo are composed chiefly of cellulose. Large quantities of starch found in the two integuments of the developing ovule disappear before maturity. Pigmentation, occurring in the cells of the two pigment layers and to a lesser extent in the palisade layer and epidermis, is associated with a hardening of the protoplast. The palisade layer is part of the inner rather than of the outer integument. The cell walls of the epidermis are composed chiefly of cellulose. Those of the perisperm and colorless layer become lignified before maturity. In the two pigment layers the walls appear to be composed of lignocellulose. The palisade layer of the seed coat contains cellulose and lignocellulose.

Results of cotton variety experiments, 1930-32. P. H. KIME (*North Carolina Sta. Agron. Inform. Circ.* 78 (1933), pp. [2]+4).—Recommendations based on further varietal trials (E.S.R., 64, p. 832) include certain strains of Mexican and Cleveland cotton for the Piedmont; of Cleveland, Mexican, and Farm Relief for the upper Coastal Plain; of Foster and Farm Relief for heavy and poorly drained soils in the lower Coastal Plain; and of Dixie-Triumph, Dixie, and Clevevilt cotton for wilt-infested soils. A table of percentages of different lengths grown in North Carolina showed that the

percentage of $\frac{1}{4}$ in. and longer cotton grown in 1932 was more than three times as large as in 1928.

Outlines of cotton culture in the San Joaquin Valley of California, J. W. HUBBARD (*U.S. Dept. Agr. Circ. 256 (1933), pp. 8, figs. 4*).—Practical information is given on selection of land and seed, time of planting, stands, chopping, cultivation, root development in relation to irrigation, effects of irrigation, and on ripening in early crops.

The effects of topping Egyptian cotton plants, J. TEMPLETON (*Egypt Min. Agr., Tech. and Sci. Serv. Bul. 103 (1931), pp. [1]+9, pls. 2*).—Topping Zagora Egyptian cotton plants in the seedling stage resulted in the production of a monopodium in the axil of each cotyledon, the larger appearing in the axil of the larger cotyledon, and the cotyledons grew larger and persisted much longer than normally. Topping before sympodia had started resulted in several monopodia, usually 1 in each of the 3 or 4 leaves carried at this time. In both cases flowering started later than in controls. When plants with sympodia were topped they were marked by vigorous growth and branching, a more erect position, and abnormally large and dark green leaves. When plants were topped at 3-week intervals from April 7 (seedling stage) to July 18, starting with the earliest toppings the yield fell off rapidly and then rose gradually with the later toppings, but in no case did topped plants yield as much as the controls.

Effect of rate of seeding upon comparison of varieties of oats, J. W. HOPKINS (*Canad. Jour. Res., 7 (1932), No. 1, pp. 1-50, figs. 6*).—The Abundance, Banner, and Daubeney oats varieties were sown at various rates in 1924, 1925, and 1926 at institutions in four Canadian provinces, with the object of obtaining a series of differences in yield between adjacent check and rate plats to be tested by Student's method. Each of 33 plats of a variety at each center consisted of nine drills 18.5 ft. long and usually 7 in. apart; the plat harvested was 1 rod long, with the two outside rows discarded. The number of plants and tillers in the central one of the remaining seven rows was determined, but the row was not used otherwise. The other six rows were harvested separately as two 3-row plats, so that each rate of seeding (four for each variety) occupied eight such 6-row plats, or sixteen 3-row plats.

The method of experimentation adopted was considered in the light of the principles of randomization and local control developed by R. A. Fisher. The plats sown at each rate were adequately replicated, but their systematic arrangement precluded a valid estimate of the errors in yield comparisons. The arrangement of the plats sown at different rates was shown to coincide to some extent with variations in soil fertility.

Differences in yield between plats of the same variety planted at different rates usually were small. The small-seeded Daubeney showed the greatest variations; the expected stabilizing effect of its greater tendency to tiller did not appear. The combined results indicated that the optimum seeding rate may not be the same for different varieties at the same station, and certainly not the same for the same variety at different stations. Near the optimum the effect of variations in seed rate upon yield were slight, and at three stations, all three varieties might be sown at a specified uniform rate without increasing significantly the ordinary experimental error. Large fluctuations found in the percentage stand of plants recorded, due partly to unavoidable errors in counting, indicated significant differences between the stations. At three stations the optimum stand of Daubeney may have exceeded that of the other oats, although the difference was significant at only one place.

Navarro oats, T. R. STANTON (*Jour. Amer. Soc. Agron.*, 25 (1933), No. 2, pp. 108-112, fig. 1).—Navarro oats, found in cultivation in Navarro County, Texas, in 1919, and also known as Three Grain Mesh and Ferguson Navarro oats, is differentiated from other oats varieties by a distinct purplish bloom which covers the entire plant during heading and ripening, and an exceedingly short second floret rachilla segment. It is highly resistant to the smut of oats, including the physiologic races that attack red oats, but is susceptible to the oat rusts. The fact that certain plant characters of Navarro oats are more or less intermediate between varieties of *Avena sativa* and *A. byzantina* suggest a hybrid origin, although it apparently belongs to *A. byzantina*. Navarro has produced rather low yields of grain from both fall and spring seeding, and cannot be recommended for growing on farms. Nor is it especially resistant to cold, although it survived most winters at Arlington, Va. Indications are that it will be most useful in breeding for smut resistance in red oats.

The relative response of potatoes to different fertilizer elements, T. E. ODLAND (*Amer. Potato Jour.*, 10 (1933), No. 2, pp. 27-31).—Rotation and fertilizer experiments (E.S.R., 64, p. 132) at the Rhode Island Experiment Station showed that potatoes can be grown satisfactorily in such rotations without using stable manure. A fertilizer relatively high in potassium without excessive nitrogen seemed desirable. Variations in the quantity of phosphorus did not influence potato yields as much as did variations in nitrogen or potassium. Different potassium sources were about equally effective. Superphosphate and basic slag were better sources of phosphorus than rock phosphate and bone meal. Response to magnesium was observed on plats where little or no lime had been used, especially if liberal quantities of potassium and nitrogen had been applied.

Results of five years' fertilizer experiments with Irish potatoes in eastern North Carolina, C. B. WILLIAMS, H. B. MANN, and J. J. SKINNER (*North Carolina Sta. Bul.* 283 (1933), pp. 21, figs. 6).—Fertilizer experiments with potatoes made on Bladen fine sandy loam near Aurora, N.C., in cooperation with the U.S. Department of Agriculture during the period 1928-32, comprised studies of formulas, time of application, sources and quantities of potash and nitrogen, and ratios of inorganic to organic nitrogen.

On this soil 1 ton per acre of a well-balanced fertilizer applied at planting resulted in greater yields of potatoes than did smaller or larger quantities of fertilizer. Mixtures containing 6 to 7 percent phosphoric acid, 6 to 8 percent ammonia, and 5 to 6 percent potash proved most effective. Better returns were had from potassium chloride than other potash sources. Ammonium sulfate and sodium nitrate as nitrogen sources gave yields approximately the same, but generally lower than from mixtures of these salts with organic nitrogen carriers. Synthetic nitrogen salts compared favorably with sodium nitrate and ammonium sulfate, but likewise were not generally as effective as mixtures of inorganic and organic nitrogen.

With varying ratios of sodium nitrate or ammonium sulfate (inorganic) and cottonseed meal (organic nitrogen), best results were generally secured when the nitrogen was derived 65 percent from sodium nitrate and 35 percent from cottonseed meal or 80 percent from ammonium sulfate and 20 percent from cottonseed meal.

Sorghums for grain and forage, B. F. KILTZ, J. B. SIEGLINGER, W. M. OSBORN, B. F. BARNES, and H. H. FINNELL (*Oklahoma Sta. Bul.* [210] (1933), pp. 47, figs. 6).—Varieties of grain sorghum and of sorgo, and for certain areas specific production practices, are recommended for seven defined regions of

Oklahoma on the basis of extensive experiments conducted by the station at Stillwater and on outlying fields, by the Panhandle Station at Goodwell, and by the U.S. Department of Agriculture at Woodward and Lawton, Okla., and at Dalhart, Tex. Varieties of both types are described, and their comparative yields in the various tests are tabulated. General cultural methods and field and harvesting practices employed in growing the crop are outlined, and adaptations as to use, climatic conditions, soils, and insect pests are discussed.

[**Sugarcane research in Hawaii**] (*Assoc. Hawaii. Sugar Technol. Rpts.*, 8 (1929), pp. 111-170, 185-255, figs. 30; 9 (1930), pp. 65-147, 161-203, figs. 41; 10 (1931), pp. 3-97, figs. 20; 11 (1932), pp. 3-35, 51-140, figs. 59).—The reports of the eighth, ninth, tenth, and eleventh annual meetings of the Association of Hawaiian Sugar Technologists, held at Honolulu in October 1929, 1930, 1931, and 1932, respectively, contain a number of papers of interest to agronomists.

The 1929 report comprises **Increasing Yields and Maintaining Juice Qualities**, by R. Conant (pp. 111-117); **Variety Problems of Arid and Unirrigated Plantations**, by E. E. Naquin (pp. 119-123); **Seedlings**, by J. L. Nicoll (pp. 125-139); **The Effect of Fertilizer on Root Distribution**, by W. Wolters (pp. 141-159); **Chemical Weed Control on Irrigated Plantations**, by K. B. Tester (pp. 161-170); **A Java Sugar Plantation**, by W. W. G. Moir (pp. 185-195); **Distribution of Factory Mud over Irrigated Fields**, by F. W. Broadbent (pp. 197, 198); and **Fertilizers**, by G. R. Stewart et al. (pp. 199-255).

Papers presented at the 1930 meeting included **The Reduction of the Trash Content of Harvested Cane**, by W. Wolters (pp. 65-81); **Soil Preparation—Plowing, etc.**, by J. L. Nicoll (pp. 83-102); **Report of the Committee on Experimental Technique**, by R. J. Borden (pp. 103-114); **Pre-harvest Sampling of Cane**, by F. W. Broadbent (pp. 115-117); **Points on Cane Ripening**, by O. H. Lyman (pp. 119-126); **Studies on the Response of Cane Growth to Moisture**, by H. R. Shaw (pp. 127-147); **Seedlings**, by A. J. Mangelsdorf (pp. 161-174); and **The Plant Food Problem**, by W. W. G. Moir (pp. 175-203).

The following papers are included in the 1931 report: **Cane Disease Control through Adjustment of Plantation Practices**, by J. P. Martin (pp. 3-11); **Cane Cultivation on the Unirrigated Districts of Hawaii**, by G. Ross (pp. 13-18); **Five Studies of Experimental Technique**, by R. J. Borden (pp. 19-30); **Whys and Wherefores of Plowing and Planting**, by S. L. Austin (pp. 31-33); **Weed Control**, by J. D. Bond (pp. 35-43); **Progress Report on Mitscherlich Pot Method of Testing Soil Fertility**, by D. A. Cooke (pp. 45-55); **Response to Forms and Time of Fertilization**, by W. W. G. Moir (pp. 57-70); **Benefits Derived from Field Experiments on Unirrigated Plantations**, by E. E. Naquin (pp. 71-83); **Root Pressure of the Sugar Cane Plant in Relation to Soil Moisture**, by D. M. Weller (pp. 85-91); and **Fertilizer Practices and Problems on Unirrigated Plantations**, by W. C. Jennings (pp. 93-97).

The 1932 report embraces articles on **Cultivation of Ratoons under Unirrigated Conditions on Kauai**, by W. P. Alexander (pp. 3-30); **Cultivation on Unirrigated Plantations on the Island of Hawaii**, by R. Bryan (pp. 31-35); **A Discussion of Some Problems in Variety Work and a Summary of the Newer Varieties of Promise**, by C. G. Lennox (pp. 51-57); **The Puerto Rican Sugar Industry and the Fourth Congress of the International Society of Sugar Cane Technologists**, by W. W. G. Moir (pp. 59-70); **Determining the Irrigation Requirements of Sugar Cane and Adjusting Field Practice to Meet These Requirements at Honolulu Plantation**, by R. Penhallow (pp. 71-98); **Progress in Plant Nutrition Studies**, by F. E. Hance (pp. 99-109); **Methods of Applying Fertilizers**, by G. W. Fisher (pp. 111-116); and **Short Cropping on Unirrigated Plantations**, by W. C. Jennings (pp. 117-140).

The composition of the spring growth of sweet clover as influenced by previous fall treatment, C. J. BADGER and H. J. SNIDER (*Jour. Amer. Soc. Agron.*, 25 (1933), No. 2, pp. 105-108).—The influence of removing a fall hay crop upon the composition of sweetclover the following spring at about the stage of growth when it is usually plowed under as green manure was studied by the Illinois Experiment Station. Analysis of the tops and roots showed that removal of the fall growth reduced the total dry matter, total nitrogen, phosphorus, and potassium in the following spring growth. Cutting for fall hay appeared to reduce the vitality or winter resistance of the sweetclover plants, which was reflected in a thinner stand and a less vigorous spring growth.

Sweet clover as a soil improvement crop for orchards, O. W. DAVIDSON (*New Jersey Stat. Circ.* 269 (1933), pp. 4).—Brief statements on the value of sweetclover for soil improvement and green manure in orchards, on its cultural needs, and on the production of green material and total nitrogen and the availability of its nitrogen, are based largely on results of experiments made at New Brunswick.

[Tobacco research in Connecticut] (*Connecticut State Sta. Bul.* 347 (1933), pp. 280, 281).—Experiments with tobacco (E.S.R., 67, p. 383), continued at the Tobacco Substation at Windsor and reviewed briefly, comprised tests of sources of potash (E.S.R., 67, p. 381), use of stable manure on shade tobacco, curing shade tobacco under controlled temperature and humidity and shed conditions, study of nitrification of nitrogen carriers, and control of potato flea beetle on tobacco with barium fluosilicate.

The distribution of nitrogen in tobacco when the supplies of nitrogen and of light are varied during the growing period, W. S. EISENMENGER (*Jour. Agr. Res. [U.S.]*, 46 (1933), No. 3, pp. 255-265).—Havana seed tobacco plants were grown for one month in water cultures in a greenhouse at the Massachusetts Experiment Station. Half of the plants were then removed to a dark room and half were continued in the light. Sodium nitrate was supplied continuously to half of each group and withheld from the other half for 11 days before harvest.

Analyses for various nitrogen fractions showed the stems to be relatively richer in total nitrogen and ammonia than were the other plant parts, while the leaves were characterized by a relatively high content of dry matter and protein. Plants without a nitrogen supply for 11 days maintained an ample supply of nitrate nitrogen in the tissue. Those grown in the dark contained a higher percentage of nitrate nitrogen than corresponding plants grown in the light. Plants liberally supplied with nitrate nitrogen with a disproportionately low supply of other nutrients contained a low percentage of dry matter and a high percentage of nitrate nitrogen, indicating a low metabolic rate. The nitrate and alpha-amino acid nitrogen content of the plants seemed to be influenced most by light, darkness usually increasing the percentage of nitrogen. The maximum percentage of nitrate nitrogen in all cases was found in the midvein of the leaf, suggesting that considerable reduction of nitrogen occurred in or near the veins of the leaf.

Spring wheat varieties for North Dakota, T. E. STOA (*North Dakota Sta. Circ.* 46 (1932), pp. 20, figs. 4).—Varieties of spring wheat are recommended for different sections of the State on the basis of extensive tests by the station and the U.S. Department of Agriculture, working in cooperation and independently. The history and agronomic characteristics of important varieties, the milling and baking values of common wheats and the macaroni value of durums, and the suitability of different varieties for combine harvesting

are described with remarks on standardization of varieties and on diseases of wheat and their control.

Marquis, the standard hard red winter wheat, currently most commonly grown and preferred by buyers of bread wheat, is susceptible to stem rust, and should be produced in sections where possibilities of rust injury are small. Ceres, the outstanding and most promising wheat of this class, which generally outyielded Marquis in extensive tests, is moderately resistant to stem rust, more susceptible than Marquis to bunt and loose smut, is more drought resistant, and resembles Marquis in milling and baking characters, is indicated particularly for eastern North Dakota when a hard red spring variety is wanted and to replace Marquis where it is unsatisfactory. Marquillo and Hope were more resistant to stem rust, leaf rust, and bunt than Marquis, but were not so satisfactory in yield and certain other characters. Reward, the most promising early wheat, averaged below Marquis in yield. Of the leading high quality durums, Kubanka is more resistant to rust and drought, although Mindum yields higher under normal conditions. Monad and Pentad are very rust resistant but unsatisfactory for macaroni.

Wheat varieties for the Columbia River Basin of Oregon. D. E. STEPHENS, R. B. WEBB, and J. F. MARTIN (*Oregon Sta. Bul.* 308 (1932), pp. 37, fig. 1).—The yields of winter and spring wheat varieties are reported from field-plot and nursery trials at the Moro and Pendleton Substations and nursery trials at six other points in the Columbia River Basin, conducted in cooperation with the U.S. Department of Agriculture.

Hybrid 128 and Turkey, C.I. No. 1571, made the highest average yields of the winter wheats in plat trials for long periods at Moro, while Hybrid 128 × Fortyfold (C.I. No. 10066) and North Powder, a Turkey selection, averaged highest during recent years. Federation, Hard Federation, Onas, and White Federation led the spring wheats in field plats. In the Moro nursery trials, White Odessa and Federation from fall seeding yielded highest over a long period. Selections from Fortyfold × Federation and Arcadian × Hard Federation averaged highest since 1926, and Federation, Currawa, Onas, and White Federation led the spring wheats.

At Pendleton, Federation averaged highest on the winter wheat field plats, and was followed by Fortyfold × Federation (C.I. No. 8247), which yielded highest in nursery trials. Their high yield and smut resistance made promising two other newer hybrid selections, Hard Federation × Martin and White Odessa × Hard Federation. Federation, the leading wheat variety in eastern Oregon, and Onas yielded highest in the spring wheat nursery and plats.

Selections from Fortyfold × Federation, Fortyfold × Hard Federation, and Arcadian × Hard Federation usually produced the highest yields in all winter wheat nurseries during the last four years. It is held that these early maturing high-yielding wheats, when further improved for hardiness and smut resistance, should replace other varieties in the Columbia River Basin. The wheats of the Turkey type tested higher in weight per bushel than did the hybrid selections. Oro and Rio, highly smut-resistant, pure-line selections from Turkey, distributed to farmers, seemed likely to replace other hard red winter wheats in areas where they are now grown. Onas, Federation, White Federation, and Hard Federation produced the highest yields as spring wheats.

Report of seed analyses, 1932 (*Penn. Dept. Agr. Bul.* 515 (1933), pp. 61).—The germination, purity, and weed seed content are tabulated for about 1,540 samples of agricultural seed collected in Pennsylvania during 1932.

Official Seed Testing Station for England and Wales: Thirteenth annual report, 1929–1930. A. EASTHAM (*Jour. Natl. Inst. Agr. Bot.*, 3 (1932),

No. 2, pp. 202-217, figs. 2).—The average germination and purity of 23,477 samples of agricultural seed, received from different sources in these countries during the year ended July 1930, are tabulated and discussed, and examination questions on the principles and practice of seed testing are appended.

HORTICULTURE

[**Horticulture at the Connecticut State Station**] (*Connecticut State Sta. Bul.* 347 (1933), pp. 273, 278, 279).—A brief report is given upon the results of the examinations of samples of vegetables, including celery, lettuce, cabbage, and string beans, and of apples for arsenical residues. The results of breeding work with sweet corn, beets, and strawberries are briefly discussed, together with the results of strain tests of New York lettuce.

[**Horticulture at the Florida Station**], R. W. RUPRECHT, G. H. BLACKMON, H. MOWRY, M. R. ENSIGN, A. F. CAMP, A. L. STAHL, L. W. GADDUM, J. H. JEFFERIES, W. E. STOKES, and R. V. ALLISON (*Florida Sta. Rpt.* 1932, pp. 59-63, 64, 96-112, 118-127, 158-163, 174-176, 184-187, 213-217, figs. 10).—Among studies upon which reports are made are the effect of potash on the composition and yield of citrus trees; the fertilizer and rootstock requirements of the Satsuma orange; the effect of the source of potash on the citrus crop; the fertilizer requirements of citrus trees grown on muck soil; the composition of pecan nuts as influenced by fertilization and soil types; the effect of various fertilizer formulas on citrus production; the use of concentrated fertilizers for citrus; the response of pecans to soil type and locality; the use of fertilizers and cover crops in pecan orchards; variety and stock trials with pecans and walnuts; cracking and cold storage trials with pecans; variety tests of grapes; cultural and fertilizer trials with tung-oil trees; varietal trials with plums, apples, and other fruits and various ornamentals; the grading and packing of Florida produce; strain and variety tests with vegetables at Sanford; the fundamental physiology of citrus fruit production; avocado maturity studies; the relation of nitrogen absorption to food storage and growth in the pecan; the preservation of citrus juices and pulps; and the cold storage of citrus fruits.

Miscellaneous propagation, varietal, fertilizer, and cultural trials with citrus are reported on from the Citrus Substation.

Among investigations reported from the Everglades Substation are tests of landscape and windbreak plants, peach, plum, avocado, and citrus, and various forest trees.

At the Subtropical Substation data are reported on fertilization of avocados and of truck crops and variety trials with vegetables.

[**Horticulture at the Georgia Station**] (*Georgia Sta. Rpt.* 1932, pp. 37, 38, 39-47, 48, 49, figs. 6).—Brief reports are presented on various activities, including studies on the preservation of fruits by freezing; factors limiting the longevity of peach trees; shipping containers for Georgia fruits; the effect of fertilizers on the germination of vegetable seeds; the value of the Austrian winter pea as a cover crop for vegetables; pecan propagation; the resistance of the tung-oil tree to winter injury; the effect of the March freeze of 1932 on various fruit crops; and the pruning of Muscadine grapevines.

In addition varietal and fertilizer trials with fruits and vegetables at the Mountain Substation are reviewed briefly.

[**Horticulture at the Kansas Station**] (*Kansas Sta. Rien. Rpt.* 1931-32, pp. 50-54, 120, 121).—Among studies herein reported are orchard investigations, including spraying, methods of pruning, soil management experiments, and varietal tests, by R. J. Barnett, G. A. Flinger, and W. F. Pickett; small fruit

investigations, by Barnett; flower and vegetable investigations, by W. B. Balch; forest tree investigations, by E. W. Johnson; and variety tests at the Fort Hays Substation with grapes and iris.

[**Horticulture at the New Mexico Station**] (*New Mexico Sta. Rpt. 1932*, pp. 59-66, 68-70, 72, 73, figs. 3).—In this progress report (E.S.R., 67, p. 35) there are set forth the results of the effect of spring freezes on the set of fruits; of variety tests with pecans; of the effect of soil type and of plant protectors on the yield of several varieties of tomatoes; of fertilizer trials with cabbage; of fertilizer, irrigation, and general cultural and breeding trials with onions; and of irrigation trials with beans.

[**Horticulture at the Rhode Island Station**] (*Rhode Island Sta. Rpt. [1932]*, pp. 47, 48, 53, 54, 55, 56).—Results are briefly presented of variety studies with sweet corn; sulfate of ammonia v. nitrate of soda trials with ornamental shrubs; breeding lettuce and eggplant; fertilization of greenhouse crops of tomatoes (E.S.R., 68, p. 476); winter gladiolus culture; fertilizer experiments with grapes; the grafting of vinifera grapes; and blackberry breeding.

The High Plains farm garden, F. P. ESHBAUGH ([Oklahoma] *Panhandle Sta., Panhandle Bul. 48* (1933), pp. 14).—Information is presented on the planning, planting, and care of the vegetable garden, with notes on various crop plants and varieties thereof. In a test of cucumber varieties the Arlington White Spine was most productive in 1929 and 1930. Mulching with straw made possible the production of a partial crop of Irish potatoes.

The quality of vegetable seeds on sale in New York in 1932, M. T. MUNN (*New York State Sta. Bul. 618* (1933), pp. 46, figs. 2).—In confirmation of earlier reports (E.S.R., 67, p. 130) herein is presented, largely in tabular form, the results of the examination, purity analysis, germination test, and field performance of 1,004 samples of packet and bulk vegetable seeds purchased in the open markets of New York State during the planting season of 1932. Seed of the same kind and variety varied widely as to freedom from weed seed and inert matter and germinating capacity. The field tests made from 622 of the packets showed wide differences in quality, from a capacity to yield excellent crops to others showing little if any care in breeding, harvesting, and packaging.

The results of spray residue studies on vegetables in 1932, H. C. McLEAN and A. L. WEBER (*N.J. State Hort. Soc. News, 14* (1933), No. 3, pp. 490, 491).—In this report on spray residue activity in New Jersey, the authors state that severe trimming of the outer leaves reduced the arsenical residue of cabbage and cauliflower below the prescribed tolerance, although originally carrying an excess. In cauliflower the residues were found to be largely located at the junction of the leaves with the main stem, and no residues were found on the flower parts. The later the plants were sprayed or dusted the more leaves and stalk that had to be removed to meet requirements.

Study of the life history of Brassica oleracea, O. H. PEARSON (*Bot. Gaz., 94* (1933), No. 3, pp. 534-550, figs. 16).—At the California Experiment Station it was found in studies with cauliflower, broccoli, and cabbage that the inflorescence is typically racemose, although sometimes paniculate. Anthesis was brought about by the rapid growth of petal and filament, which forced apart the sepals, exposing the anthers and stigma. Pollination was accomplished by insects.

The haploid number of chromosomes in the pollen mother cell was 9. Pollen grew readily in 20 percent sucrose solution at 15° to 20° C. Viability was maintained satisfactorily for 7 days at 11°, while at 4° and 30° viability was lost on the third and second days, respectively.

The embryo did not develop noticeably for at least 4 days after fertilization, grew slowly at first, and did not fill the ovule until about the thirty-second day. However, seeds planted within 33 days after pollination germinated and grew.

Materials for temporary home storage of celery, C. E. STEINBAUER (*Minn. Hort.*, 59 (1931), No. 9, p. 216; *abs. in Minnesota Sta. Rpt. 1932*, p. 34).—Of six substances, namely, peat, shavings, loam soil over concrete blocks, sand, loam soil, and half sand and half peat, used for packing about the roots of stored celery, peat was the most successful, with shavings giving fairly good results.

A comparative test of some pepper varieties, A. E. HUTCHINS (*Minn. Hort.*, 60 (1932), No. 5, pp. 104, 121; *abs. in Minnesota Sta. Rpt. 1932*, p. 31).—The results are presented of a test of 13 varieties of garden peppers with relation to yield, average number and weight of fruits per plant, and the weight and average thickness of flesh per fruit. Harris Earliest and Harris Early Giant were earlier and more productive than any of the other varieties.

The most important varieties of spinach [trans. title], N. NICOLAISEN (*Züchter*, 5 (1933), No. 1, pp. 1–8, figs. 16).—Technical descriptions are presented of 28 varieties of spinach studied in an attempt to establish standard types.

Effects of fertilizers and rotation on earliness and total yields of tomatoes, C. B. SAYRE (*New York State Sta. Bul.* 619 (1933), pp. 50, figs. 5).—The results of experiments continued over a period of six successive seasons led to the conclusion that phosphorus was the most important nutrient in increasing the early and the total yields of tomatoes. Nitrogen was second and potash third in importance, the latter substance returning a profit when used in connection with adequate quantities of nitrogen and phosphorus. The best form in which fertilizers were applied was a complete mixture high in phosphorus. With respect to effect on yield, moderately high analysis fertilizers compared favorably with strongly concentrated materials when judged from the standpoint of equivalent amounts of actual plant food. Manure was found to be an excellent fertilizer but was improved by the addition of a complete fertilizer high in phosphorus or available phosphorus alone.

Yields with any given variety and treatment varied greatly from year to year, due apparently to variations in temperature, rainfall, and the frost-free period. The following 4-year rotation proved very satisfactory for the tomato crop: First year, tomatoes followed by rye; second year, snap beans followed by rye; third year, beets; and fourth year, cannery peas followed by sweetclover.

Decoloration, ripening, and coloration of tomatoes with ethylene gas, R. B. HARVEY (*Minn. Hort.*, 59 (1931), No. 8–9, p. 189).—Green tomatoes are said to contain two green pigments known as chlorophylls and two yellow pigments, carotene and xanthophyll. In yellow varieties, with ripening the green pigments are lost, leaving the characteristic yellow color. In red varieties, coincident with the loss of green there develops a red pigment called lycopin, of the same empirical chemical formula as carotene. Upon exposure of immature tomatoes to ethylene, chlorophyll decomposition is hastened and ripening speeded. At temperatures above 32° C. (89.6° F.) red coloration fails to occur, but if such fruits are removed to a lower temperature, 20° to 30°, they form red pigment and within 5 days take on a normal color. Evidently the mechanism for the production of lycopin is not effective at temperatures above 32° but is not destroyed.

Artificial refrigeration as a means of studying winterhardiness, R. B. HARVEY (*Jour. Amer. Soc. Agron.*, 23 (1931), No. 12, p. 1064; *abs. in Minnesota Sta. Rpt. 1932*, p. 28).—Long experience with the artificial winter test indicated that it was the most reliable method of estimating the rate of hardening and the hardening capacity of plants.

Hardiness of tree fruits and the artificial winter test, R. B. HARVEY (*Minn. Hort.*, 60 (1932), No. 1, p. 18).—Discussing hardiness in plants, the author states that hardiness of plant tissues can be determined quickly by exposing the tree or branches thereof in a refrigerated space. Two hours at the freezing point daily for 5 days sufficed to harden plants, even though the remaining hours were warm. The limit necessary to maintain hardiness was about 1 hour at the freezing point in each 48 hours at 65° F. Only the progeny of hardy plants possessed the ability to acquire hardiness.

Methods used to breed new varieties, R. WELLINGTON (*Minn. Hort.*, 61 (1933), No. 5, pp. 83-85, figs. 8).—Illustrating the various steps employed at the New York State Experiment Station in the development of new fruits, the author describes certain of the resulting apple, raspberry, and strawberry seedlings and discusses the organization used for disseminating promising seedlings to the growers.

Fruitfulness in pomological plants, J. V. NATIVIDADE (*A Improdutividade em Pomologia. Alcobaca, Portugal: José de Oliveira, Jr., 1932, pp. 229, pls. 50, figs. 98*).—Supplemented by an extensive survey of pollination studies in various parts of the world, the author presents results of histological and cytological studies with various Portugal-grown fruits. Differentiation of flower buds was first observed in the Bismarck apple at the end of June and in the Casa Nova de Alcobaca the first days of July, with the first indication of anther differentiation on January 15 and February 10, respectively. The haploid number of chromosomes in the pollen mother cells of the Molar Fina almond, Comum apricot, Branco-rosa peach, and Galega, Vidrada, and Saco cherries was 8, with 24 in the Reine Claude plum and 12 in the Garrfal cherry, *Prunus avium* × *P. cerasus*. In the Reine Claude plum (hexaploid) meiosis proceeded with great irregularity due to polyploidy. In the apple there were distinguished two important groups (1) varieties with 17 haploid chromosomes, and (2) a group with a diploid number of 51 and marked irregularity in the reduction divisions.

Pollination of fruit trees in West Virginia, H. E. KNOWLTON (*West Virginia Sta. Circ. 62* (1933), pp. 12, figs. 9).—Information is presented on the processes and need of pollination in fruits, on sterility and its causes, and on the problem as related to apples, peaches, cherries, plums, and pears. Suggestions are made for the provision of adequate pollination by the interplanting of compatible varieties, introduction of bouquets of compatible bloom, and the use of bees. The relation of nutrition to the set of fruit is pointed out.

Spraying fruit plants, W. F. PICKETT and G. A. FILINGER (*Kansas Sta. Circ. 169* (1932), pp. 34, figs. 21).—In this revision of an earlier circular (E.S.R., 61, p. 141), there is presented information on diseases and insects, their nature and importance, supplemented with spray schedules and other suggestions for control. In the case of crown gall and orange rust of brambles, diseases not susceptible to control by spraying, the authors suggest that care should be exercised to secure disease-free plants.

Success and failure in spraying for scab and codling moth, G. L. RICKS and W. TOENJES (*Michigan Sta. Spec. Bul. 230* (1933), pp. 32, figs. 22).—Studies in representative commercial orchards in Allegan and Van Buren Counties showed that certain growers are much more successful than their neighbors in controlling apple scab and codling moth. An analysis of the situation indicated that thoroughness of coverage rather than differences in spraying schedules or in materials used was the principal factor concerned. In the average orchard more scabby and wormy fruits were found in the upper than lower halves of the trees, due obviously to the fact that the lower portion was

covered more thoroughly. Unless trees in heavy foliage were sprayed so that the material passed beyond the center of the tree, fruits were often coated on one side only and subject to codling-moth invasion. Where trees were thoroughly covered with spray the codling moth population was greatly reduced in one season, especially if the applications were timed with bait trap records. Concluding, the authors assert that successful spraying depends more on the individual operating the spray gun than on any other single factor.

Rapidly growing, succulent branches on young apple trees tend to form narrow crotch angles with the trunk, M. A. BLAKE (*New Jersey Stat. Circ.* 270 (1933), pp. 4, figs. 2).—Stating that branches which join the trunk at angles of less than 40° are likely to be weak at the junction, the author presents some data taken on 1-year-old Stayman Winesap trees which showed that spurs and branches 6 in. or less in length formed angles with the trunk averaging 83.8° , whereas 1-year-old branches 31 to 36 in. in length formed crotch angles averaging 47.1° . The disbudding of 1-year-old apple trees at planting to a few selected buds tended toward the formation of acute angles. Furthermore, in the case of disbudded 1-year-old Delicious trees the treated trees made much less growth the season of disbudding than did the control trees.

Assimilation of carbon dioxide by apple leaves under natural conditions, A. J. HEINICKE (*Amer. Jour. Bot.*, 19 (1932), No. 10, p. 845).—Studies at Cornell University showed a marked fluctuation in the hourly and daily rate of photosynthesis of apple leaves. The highest rate in over 1,000 determinations during 1- to 5-hour periods was 35 mg of carbon dioxide per hour per 100 cm^2 of leaf surface, with the most common rate between 5 and 10 mg. As a rule more carbon dioxide was absorbed in the morning than in the afternoon, but high values sometimes occurred a few hours before sunset. Under certain conditions spraying and ringing, although not visibly affecting the leaf surface, greatly reduced photosynthesis. The apparatus used was previously described (E.S.R., 68, p. 744).

A study of the ash constituents of apple fruits during the growing season, E. F. HOPKINS and J. H. GOUBLEY (*Ohio Sta. Bul.* 519 (1933), pp. 30).—Having reported in an earlier paper (E.S.R., 65, p. 833) that applications of quickly available nitrogen increased both the percentage of total nitrogen and also the actual amount of nitrogen in apples but had no apparent direct effect on keeping quality, the authors herein discuss the results of ash analyses of the flesh of apples and the possible correlation of the percentages of various constituents with the amount of breakdown in such fruit when placed in common or cold storage.

Evidence was secured that with increasing size or maturity of apples the percentages of total solids and of ash decrease and also the percentages of calcium, phosphorus, potash, and iron based on both dry and moist weights. Mineral constituents actually continued to be absorbed by the fruit during development but at a rate that was slow in comparison with the rate of increase in size. As fruit increased in size the percentage of calcium was found to decrease rapidly, that of phosphorus less rapidly, and potash to increase. Fertilizers containing potassium, especially when deficient in phosphorus, caused an increase in the percentage of total ash and in the amount of potash in the ash. At the same time the percentages of calcium and phosphorus in the ash were low, indicating that the greater intake of potash resulted in a decreased intake of certain other elements. In general a high ash content was associated with a high percentage of potash in the ash. Of the six varieties studied, namely, Stayman Winesap, Winesap, Grimes Golden, Arkansas Black, Jonathan, and McIntosh, the last named was markedly dis-

tinct, being exceptionally low in ash and calcium and high in phosphorus. The soil in which the trees were growing apparently influenced the composition of apples to some extent.

Observations on stored fruit showed no close relationship between physiological breakdown and either the nitrogen content of the fruit or the mineral content of the ash, but it is pointed out that the results may have been influenced somewhat by soil type. As noted at the station, variety and season were factors in breakdown. In years of light crops Rhode Island Greening, Stayman Winesap, Grimes Golden, and Baldwin were likely to manifest breakdown, and the trouble was accentuated by overfertilizing with manure or nitrogen. In fact any treatment inducing oversize of fruit tended toward the same result. A delay in storing and high storage temperature also tended to increase the percentage of physiological breakdown.

Embryo abortion in early-ripening varieties of *Prunus avium*, H. B. TUKEY (*Bot. Gaz.*, 94 (1933), No. 3, pp. 433-468, figs. 41).—In this contribution from the Hull Botanical Laboratory upon work carried out in part at the New York State Experiment Station, the author discusses the embryogeny of the sweet cherry with particular reference to the nature of embryo abortion, found to occur almost universally in early-maturing varieties. Apparently abortion occurred as a sudden arrest in development, with no indication that the phenomenon was associated necessarily with poor pollination, sterility, incompatibility, or even nutrition. Among cherries normally producing fruits with abortive embryos, the earliest ripening fruits contained the smallest embryos, a condition just opposite from that obtaining in late cherries.

As a practical deduction, the author concludes that early-ripening cherries should not be used as ovule parents in the origination of new varieties but that the crosses should be made in the reciprocal direction.

Artificial culture of sweet cherry embryos, H. B. TUKEY (*Jour. Heredity*, 24 (1933), No. 1, pp. 7-12, figs. 3).—At the New York State Experiment Station embryos of the Early Purple Guigne sweet cherry removed from the pits of ripe fruit on June 10, 26 days after full bloom, placed on a nutrient agar containing neither nitrogen nor carbohydrates and kept in direct sunlight in a constant temperature case failed to grow, despite slight swelling. In another instance, however, where glucose was added to the nutrient solution, chlorophyll was observed in the cotyledons within 5 days, followed by leaf and root development. The addition of amino nitrogen as well as glucose to the nutrient agar resulted in large green leaves but no roots. Nitrate nitrogen on the other hand did not inhibit root development. Comparable results were obtained with Burbank, Coe, and Governor Wood cherries.

Successful growth was also obtained with Coe and Governor Wood pits cut to expose the cotyledons to sunlight and pressed into sterile quartz sand in pots under bell jars. Seed of late-ripening varieties harvested in the period 40 to 50 days after full bloom germinated immediately. However, when such seed was allowed to develop further it failed to germinate until a period of afterripening at low temperature and high moisture was provided. Apparently the balance of reserve materials essential to induce dormancy was never reached in the aborted seeds of early-ripening cherries.

The author points out the value of the findings in practical cherry breeding, and the need of distinguishing between fruits which do not produce viable seeds because of genetically lethal factors and those like the early-ripening cherries in question which fail because of some adverse somatic relationship.

Prune maturity and storage, L. R. TUCKER and L. VERNER (*Idaho Sta. Bul.* 196 (1932), pp. 20, figs. 4).—Studies conducted in orchards in different localities

in southern Idaho (E.S.R., 63, p. 239) showed that maturity changes in the Italian prune are characterized by softening of the flesh, development of color pigments in the skin, and an increase in sugar and a decrease in acid content. When measured at a definite firmness fruit varied according to the orchard in which it was grown with regard to sugar and acid contents. A similar seasonal variation was observed for any given orchard. Firmness was found to be an apparently accurate measure of the keeping quality of stored prunes, which kept about as well in storage as they did on the tree under favorable weather conditions. At room temperature and humidity prunes softened quickly and shriveled badly, suggesting the desirability of prompt storage after picking. Other storage troubles were mold and internal breakdown, the former occurring especially abundantly where the skin was broken.

Growing raspberries in West Virginia, H. E. KNOWLTON and C. R. ORTON (*West Virginia Sta. Circ.* 61 (1933), pp. 20, figs. 9).—A general discussion is presented, including information on the present status of the industry, the location of plantings, preparation of the soil, planting, pruning, culture, importance of organic matter, fertilization, harvesting, varieties, and control of diseases, such as crown gall, anthracnose, cane blight, orange rust, and mosaic.

Raspberry pruning studies, W. G. BRIERLEY (*Minn. Hort.*, 61 (1933), No. 4, pp. 65, 67).—In addition to reviewing earlier studies (E.S.R., 67, p. 39), the author includes observations on work carried on at the Fruit Breeding Farm of the Minnesota Experiment Station in 1932 wherein it was found that if old canes were removed from red raspberries immediately after fruiting the new canes grew a little faster and a little taller and matured a week later. It is deemed likely that the beneficial effect of the early removal of the old canes is largely a matter of water conservation and probably not related to the nutrient supply.

Observations and experiments with blueberries in western Washington, D. J. CROWLEY (*Washington Col. Sta. Bul.* 276 (1933), pp. 20, figs. 7).—This is a general discussion of blueberry culture, including varieties, soil requirements, planting, pollination needs, pruning, fertilizers, propagation, and harvesting and marketing, supplemented by certain experimental results. Of fertilizers tested at the Cranberry Substation at Long Beach, a mixture of 100 lb. of nitrate of soda, 200 lb. of rock phosphate, and 50 lb. of sulfate of potash was found desirable and increased the yield almost twice that of the untreated plots the first season and more than 2.5 times in 1932. Applications of commercial fertilizer to blueberries less than 3 years old with a view to stimulating vegetative growth gave negative results.

In propagating softwood cuttings, consistently high percentages of rooting were obtained from the heel type of softwood cutting set out on May 26, June 15, and July 10, 1932. The percentage of rooting after the middle of July declined rapidly. The maximum rooting (95 percent) was obtained with heel cuttings set June 15 in a mixture of sphagnum moss and sand. Comparable cuttings in sand rooted 80 percent. Cuttings placed under cheesecloth or lath rooted as freely as those under glass. Sand used alone was difficult to handle because of its tendency to dry out rapidly during drought periods. The author points out that seedlings do not come true to seed and that they may be of little value even though the seed is harvested from cultivated varieties.

The composition of and nutrient uptake by the banana plant, with special reference to the Canaries, A. F. BAILLON, E. HOLMES, and A. H. LEWIS (*Trop. Agr. [Trinidad]*, 10 (1933), No. 5, pp. 139-144).—Studying the composition of Cavendish banana plants at the time of setting and after growth for about 18 months in brick lined pits, the authors conclude that the plants

took up from the soil a moderate amount of nitrogen, relatively little phosphate, and a very large amount of potash. The fertilizer applied was of the proportion 10.59-2.97-13.34 (N-P-K). The weights of potash in both the head and the mature plant were high. The fruit stalk was particularly high in percentage of potash and also relatively high in percentage of phosphate. The fruit was markedly deficient in percentage of lime, magnesia, and iron, most of the lime being located in the roots, stems, and leaves and most of the magnesia and iron in the roots and stems. Analyses made of the soil before and after the growing period showed a very high loss of potassium oxide from the soil, only 10 percent of which could be accounted for by the uptake by the plant. A similar condition was observed in respect to phosphorus. Presumably the potassium oxide was very rapidly leached out of the soil by the carbonated water.

Vicinism in *Aquilegia vulgaris*, E. ANDERSON and B. SCHAFER (*Amer. Nat.*, 67 (1933), No. 709, pp. 190-192).—In an experiment designed to determine the amount of outcrossing in *A. vulgaris*, no evidence was found of effective outcrossing with other species, but within the species outcrossing occurred in at least 19 of 119 possible cases.

Delphiniums: Their history and cultivation, G. A. PHILLIPS (*London: Thornton Butterworth*, 1933, pp. 256, pls. 18, figs. 18).—This book treats of the history and development of the delphinium in Great Britain, the Netherlands, France, Germany, and other European countries, and gives information on varieties, species, planting and cultivation, propagation, crossbreeding and hybridization, enemies and diseases, etc.

The book of the delphinium, J. F. LEEMING (*London: Isaac Pitman & Sons*, 1932, pp. 1X+76, pls. 7, figs. 5).—A general treatise on the growing of the delphinium.

Water lilies and water plants, A. NIKLITSCHKE (*London: Chatto & Windus*, 1932, pp. VIII+136, pls. 12, figs. 5).—A general discussion of water gardens and aquatic plants.

Commercial bulb growing: Bulbs and blooms for market (*London: Nurseryman & Seedsman*, [1933], pp. [5]+75+[2]).—A general discussion.

Preliminary report on reducing transpiration of transplanted evergreens, J. L. EMERSON and A. C. HILDBRETH (*Science*, 77 (1933), No. 2001, pp. 433, 434).—At the U.S.D.A. Cheyenne Horticultural Field Station waxes, gums, resins, oils, and asphaltic compounds, alone and in various mixtures, were tested as coatings to reduce transpiration losses from young evergreens. It was found that safe temperatures were low; for example, Colorado blue spruce (*Picea pungens*) could not withstand materials heated above 65° C. (149° F.). Tests of nontoxic oils and emulsions showed castor and corn oils to be the only noninjurious materials when used in pure form. Emulsifying some of the injurious oils reduced or entirely eliminated their toxicity. On 5-year-old dormant *Pinus austriaca* trees the daily transpiration loss was reduced by corn oil spray from 20.7 to 2.4 g and by sulfonated linseed oil emulsion from 20.8 to 8.4 g, whereas in the control trees there was an actual increase in the same period, from 20.3 to 26.3 g. No detrimental effects of the sharply reduced transpiration were noted during the succeeding months.

Gardens of fragrance, T. G. W. HENSLOW (*London and New York: Frederick Warne & Co.*, 1932, pp. XVI+224, pls. 28).—A presentation of arguments in favor of the growing of scented flowers.

The rock garden (*Michigan Sta. Spec. Bul.* 228 (1933), pp. 84, figs. 70).—This bulletin is comprised of a discussion of the design and construction of rock gardens by C. P. Halligan and a discussion of the cultural requirements and characteristics of rock garden plants by C. E. Wildon.

Rock garden plants, C. E. WILDON (*Michigan Sta. Spec. Bul.* 228 Sup. (1933), pp. 41).—In tabulated form there are presented descriptive lists of hardy herbaceous rock plants, and of annuals, bulbs, and dwarf shrubs suitable for planting in a rock garden.

FORESTRY

[Forestry at the Connecticut State Station] (*Connecticut State Sta. Bul.* 347 (1933), pp. 277, 278).—In this brief report there is discussed the relation of soil characters to the growth of trees; the composition of forest litter; the value of certain species when treated with creosote as fence post material; the distribution of forest planting stock; and the control of blister rust by eradication of currants and gooseberries.

[Forestry at the Georgia Station] (*Georgia Sta. Rpt.* 1932, pp. 49-51).—A brief report is presented of studies upon seed harvesting, storing, and germination; seed bed management; soil adaptation; and spacing and cultural requirements of various forest tree species.

Ohio Forest News, [March 1933] (*Ohio Forest News* [Ohio Sta.], No. 21 (1933), pp. 8, figs. 3).—In addition to miscellaneous information on forests and forest activities, a list is presented of maples, buckeyes, ashes, and walnuts in the Wooster Arboretum.

Improving seedbed conditions in a Norway pine forest, H. L. SHIRLEY (*Jour. Forestry*, 31 (1933), No. 3, pp. 322-328, figs. 3).—Noting in stands of virgin Norway pine on the Chippewa National Forest, Minn., that due to the dense mat of needles and surface vegetation young pine seedlings could not establish themselves despite an ample supply of seed, certain areas in a 200- to 280-year-old stand of Norway pine were disked in early September 1930. Three practices were followed: (1) 5-ft. strips of disked soil with 10-ft. intervening untouched strips, (2) the entire area disked once, and (3) the entire area disked twice in opposite directions. Observations in 1931 showed Norway pine seedlings germinating wherever the mineral soil was exposed. Seedlings were especially numerous in the bottom of disked furrows where the seed apparently was protected to some degree from birds and rodents. At the end of the second growing season there was an average of 10,620 seedlings per acre on the disked area as compared with 860 on the undisked. The single complete diskings resulted in the establishment of more pine seedlings than did diskings in strips or diskings twice in opposite directions. Supplementary seeding was found of slight value on untreated areas and of doubtful value on cultivated areas where diskings was carried out in the presence of a good seed crop.

Sustained yield of Adirondack spruce and fir, A. B. RECKNAGEL (*Jour. Forestry*, 31 (1933), No. 3, pp. 343, 344).—A study of spruce and balsam fir growth suggested the possibility of continuous production of pulpwood if spruce were cut to a lower limit of 10 in. in diameter at breast height and fir to 6 in. Under the proposed system the cut 25 years hence would be practically the same as that secured at the present time.

Aspen competition in Norway pine plantations, F. H. EYRE (*Jour. Forestry*, 31 (1933), No. 3, pp. 318-321).—A study by the U.S.D.A. Lake States Forest Experiment Station of three adjacent plantations of Norway and white pines established in 1915 and 1917 on the Superior National Forest showed a striking aggressiveness of aspen. An examination of the areas in the two or three years following planting showed satisfactory establishment, but by 1931 large patches of aspen containing only a few stunted pines were noted. The number of planted pines was observed to be annually decreasing and the rate of height growth lessening, except where Norway pine was maintaining itself.

Release cuttings removing approximately 90 percent of the basal area of the aspen required an average of 6.25 man hours per acre.

A merchantable height table for beech in the Northeastern States, H. C. HEBB (*Jour. Forestry*, 31 (1933), No. 3, p. 343).—From data collected in the White Mountain National Forest, N.H., a table is presented showing the merchantable height and volume of beech. A tendency for height to decrease above 26 in. in diameter at breast height is ascribed to the defectiveness of the tops of older trees.

American cypress and its uses (U.S. Dept. Com., Bur. Foreign and Dom. Com., Trade Prom. Ser. 141 (1932), pp. IV+28, figs. 18).—This pamphlet, prepared jointly by the U.S. Department of Commerce Lumber Division and the National Committee on Wood Utilization, presents general practical information on properties and uses of American cypress as lumber.

The Sutelj deodar: Its ecology and timber production, R. M. GORRIE (*Indian Forest Rec.*, 17 (1933), No. 4, pp. [2]+140, pls. 10).—Tracing the plant associates of the deodar cedar growing under the moist monsoon conditions of the outer hills and in the arid regions behind the main ranges of the Himalaya Mountains, there was recorded a complete change of flora, except for blue pine (*Pinus exoclesa*), which accompanied the deodar cedar everywhere, even up to the snow beds of the inner ranges. The capacity of deodar cedar to produce timber varied markedly with climatic changes, and for practical purposes the deodar itself was the best indicator of quality class. The ground flora found to indicate optimum conditions for deodar cedar in its moist and arid zones are given in tabular form.

A fast growing Douglas fir, T. J. STARKER (*Jour. Forestry*, 31 (1933), No. 3, p. 346).—Records taken on a Douglas fir tree stump located on the Oregon State College campus showed the tree to have been 65 years old at cutting and 28 in. in diameter at 3 ft. height. Certain of the annual rings were $\frac{1}{8}$ in. in width and were composed of from one half to two thirds summer wood.

Comparative radial growth of various oaks, A. C. MCINTYRE (*Jour. Forestry*, 31 (1933), No. 3, pp. 341, 342).—In this contribution from the Pennsylvania Experiment Station there are presented data on the comparative diameter growth of five oaks, namely, black, red, scarlet, white, and chestnut. Based on the width of the last 10 annual rings, black oak led in growth rate, followed in order by red, scarlet, white, and chestnut. On lower quality sites red oak grew more rapidly than black oak until reaching a diameter at breast height of 10 in., when the black oak surpassed it. White and chestnut oaks ranked the same on both good and poor quality sites. The author points out that the red, black, and scarlet oaks belonging to the black oak group surpassed the white and chestnut oaks belonging to the white oak group.

Weight of fruit of Nuttall's oak, R. K. WINTERS (*Jour. Forestry*, 31 (1933), No. 3, p. 340).—Weights taken by the U.S.D.A. Southern Forest Experiment Station in the fall of 1931 and 1932 on fruits and nuts of *Quercus nuttalli* collected in northern Louisiana and Mississippi showed 100 acorns to average 437.60 g. One lb. of acorns minus the cups and 1 lb. of acorn cups contained 103.6 and 516.5 units, respectively.

Specific gravity and related properties of softwood lumber, E. C. PECK (*U.S. Dept. Agr., Tech. Bul. 348 (1933), pp. 24, figs. 9*).—Stating that lumber is frequently compared in terms of weight, the author presents specific gravity data based on tests of sections of boards collected at sawmills throughout the United States for 14 commercially important softwoods. Arranged in descending order of average specific gravity of the heartwood were longleaf pine, shortleaf pine, western larch, Douglas fir, western hemlock, Norway pine, southern cypress, ponderosa pine, western white pine, Sitka spruce, redwood, northern

white pine, white fir, and sugar pine. The order with respect to sapwood was not exactly similar but was in much the same order. Longleaf pine, southern cypress, redwood, shortleaf pine, Douglas fir, ponderosa pine, and western larch displayed a broad range in specific gravity. In Longleaf pine, shortleaf pine, western larch, Douglas fir, and Norway pine there was noted a sharp contrast between the specific gravity of the spring wood and the summer wood. Ponderosa pine also showed a pronounced contrast, but the width of the summer wood varied markedly. In western white, northern white, and sugar pines there was only a slight contrast between spring and summer woods. In conclusion the author points out the importance of knowing not only the average specific gravity but the range in specific gravity of a species as an index to usefulness or suitability of the lumber for definite purposes. It is also deemed important to consider the contrast between summer and spring woods.

Causes of brashness in wood, A. KOEHLER (*U.S. Dept. Agr., Tech. Bul. 342 (1933), pp. 40, figs. 22*).—Brashness of the wood of any given species may result from adverse conditions during growth, or after-cutting factors, such as decay, severe bending or end compression, and subjection to prolonged high temperatures. Wood low in density for its species was found almost invariably brash, especially when dry.

Studies of the cellular structure of low-density wood showed a smaller amount of wood substance and a greater slope with respect to the cell axes of the fibrils in the walls of the cells in the predominating tissues. Species of normally low density were not characteristically brash but were found relatively weak.

In some oak the wood fibers were comparatively few in number, being replaced by other tissues which did not contribute so much to strength but were often just as heavy. Another weak type, namely, compression wood, formed on the lower side of leaning softwood trees, was found wide ringed, with a relatively large percentage of summer wood. Compression wood is brittle, and when dry ranks low in toughness and certain other strength properties. Wood subjected to either severe bending or end compression was observed to develop failures in the fiber walls, which may cause early failure under stress and abrupt fractures on the compression side.

With respect to the effect of prolonged high temperature, the indications were that abrupt fractures are not produced unless a temperature high enough to darken the wood is employed. In decayed wood shock resistance may be decreased even before the decay has advanced far enough to be easily recognized; hence the author suggests that no wood showing the least decay should be used where a high degree of toughness is required.

DISEASES OF PLANTS

Fungous diseases of plants, J. ERICKSSON, trans. by W. GOODWIN (*London: Baillière, Tindall & Cox, 1930, 2 ed., pp. VII+526, figs. 399*).—"This volume presents a general review of the more important fungus diseases which occur in northern and mid-Europe on field and garden crops and on certain trees of economic or ornamental value. Alongside the description of the various diseases are given the methods to be adopted for their prevention and control. Some of the diseases described are, so far, only known in other countries, but . . . may at any time make their appearance in northern and mid-Europe. Some new material which was not available at the time of the publication of the German edition, 1927-28 [E.S.R., 60, pp. 828, 829], is included in this edition, more particularly in the chapter on cereal and grass

rusts and in connection with certain diseases on peach, chestnut, and elm trees. . . . References to some of the chief publications follow the descriptions of the chief groups of fungi and forms of disease."

Mosaic disease of *Brunella vulgaris* [trans. title] J. I. LIRO (*Ann. Soc. Zool. Bot. Fennicae Vanamo*, 11 (1930), pp. 143-149, fig. 1).—It is claimed to have been found that different species of leaf lice are able to spread a mosaic attacking *B. vulgaris* under natural conditions.

Studies on tracheomycoses, R. VAN DER VEEN (*Onderzoekingen over Tracheomycosen. Proc[schr., Rijks-Univ., Utrecht*, 1930, pp [6]+89, figs. 23).—This deals systematically in its several main sections with symptoms of tracheomycoses and a description of the causal agents (*Fusarium* sp. and *Verticillium* sp.), nutritional physiology of the fungus in pure culture, influence of nitrogen manuring on infection, the role of toxins in relation to the wilting, and the possibility of immunization.

The use of formaldehyde dust in growing seedlings, J. D. WILSON and P. E. TILFORD (*Ohio Sta. Bul.* 520 (1933), pp. 40, figs. 5).—Stating that there are two major methods of soil sterilization, (1) the use of high temperatures, and (2) of lethally toxic chemicals, the authors herein discuss the results of a number of experiments upon the influence of certain soil and other factors on the toxic effects of formaldehyde on various fungi and on vegetable and flower seeds and seedlings.

The mass treatment of soil at the rate of 8 oz. of a 6 percent formaldehyde dust per bushel of soil with few exceptions improved the stand of seedlings of many flowers and vegetables. Campanula, petunia, lettuce, and turnip seeds were often injured, and larkspur, gallardia, carrot, corn, endive, and parsnip were not usually benefitted. The authors advise that seeds of the susceptible group, old seed, and weak seed should not be planted until 24 hours after treatment of the soil. The optimum dosage for the control of damping-off was found to be from 8 to 12 oz. of a 6 percent dust per bushel of soil, varying somewhat with the type of soil.

Field experiments in which formaldehyde dust was applied in the row with the seed showed considerable difference in susceptibility of species to injury. For plants rather sensitive to formaldehyde a 4.5 percent dust applied at the rate of 1 oz. per 30 ft. of row is recommended. Watering thoroughly directly after planting largely eliminated formaldehyde injury to the seed. In general the toxicity of formaldehyde decreased as the organic content and fineness of the soil increased. Drenching with a formaldehyde solution proved more harmful than dust in the rows. Mass treatment proved too costly for field use.

When seedlings were being transplanted a delay period of 72 hours was necessary following treatment to avoid injury. However, formaldehyde escaped more readily from warm, dry soil than from cold, wet soil. Here again the fineness of the soil and the increased organic content decreased injury. Finely divided carriers, such as charcoal dust and infusorial earth, permitted a more rapid escape of formaldehyde than did kaolin or muck, and hence tended to reduce injury. The use of 6 percent formaldehyde dust at the rate of 8 oz. per bushel of soil killed *Pythium debaryanum*, *Sclerotium delphini*, *Fusarium lycopersici*, and the mycelium but not the sclerotia of *Rhizoctonia solani*. The nematode population of screened soil was reduced materially by formaldehyde dust treatment.

Carbon disulfide emulsion for the control of the root-knot nematode, E. F. GUBA (*Massachusetts Sta. Bul.* 292 (1932), pp. 16, figs. 3).—Stating that root knot caused by the nematode *Heterodera radicicola* is the most prevalent and destructive disease of greenhouse cucumbers and tomatoes in Massachusetts and the most costly to control, the author reports that in greenhouse experiments

with tomatoes carbon disulfide emulsion proved to be an effective nemacide and if used properly may be relied upon to eliminate nematodes as a serious factor in crop losses. A stock solution containing 68 percent carbon disulfide, 26 percent water, and 6 percent rosin fish oil soap was diluted in water to make a 1:50 concentration and applied at the rate of 1 gal. per square foot of soil. Where soil pathogenes are present the addition of formaldehyde is recommended.

Sanitation, which includes the removal of infested roots when the houses are cleaned out, decay of root material remaining, and thoroughness of application, contributed much to the effectiveness of the carbon disulfide treatment. Allowing the beds to lie idle for 2 or 3 weeks after the old crop was removed assisted materially in the decay of the old roots. A delay of one week after the carbon disulfide treatment was found necessary before planting. The exposure to carbon disulfide for more than 5 hours at one time may cause illness to the workman.

[Control of plant diseases in Connecticut] (*Connecticut State Sta. Bul.* 347 (1933), pp. 274, 275).—Brief notes on the value of a spray of lime, lead arsenate, and fish oil for sooty blotch and apple scab, the value of calcium cyanamide for controlling clubroot of cabbage and cauliflower, and spraying potatoes with 8-8-50 Bordeaux mixture are given.

[Plant disease studies by the Florida Station] (*Florida Sta. Rpt.* 1932, pp. 58, 59, 128-148, 151, 152, 199-202, 207, 208, fig. 1).—Data are given from studies of die-back of citrus, by B. R. Fudge (pp. 58, 59); the gumming of citrus, by A. S. Rhoads (p. 129); melanose and stem-end rot of citrus, by G. D. Ruehle and W. A. Kuntz (pp. 129, 130); citrus canker, by K. W. Loucks (pp. 130, 131); citrus scab and its control, by Ruehle (pp. 131, 132); nail head spot of tomatoes, by G. F. Weber (p. 132); a decay of strawberry roots caused by *Sclerotium rolfsii*, by A. N. Brooks and R. E. Nolen (pp. 132, 133); late blight, scab, rhizoctonosis, brown rot, and other potato diseases, by A. H. Eddins (pp. 133, 134); diseases of corn caused by *Physoderma zeae maydis*, *Diplodia* spp., and *Fusarium* spp., by R. K. Voorhees (pp. 134-137); control of diseases of Easter lily, gladiolus, and narcissus bulbs, by W. B. Shippy (pp. 137, 138); resistance to *Fusarium* wilt and mosaic of watermelons, by M. N. Walker (pp. 138-141); the so-called "rust" of *Asparagus plumosus*, by Shippy (p. 141); control of tomato wilt, by Weber and D. G. A. Kelbert (p. 142); *Clitocybe* mushroom root rot of citrus and other woody plants, by Rhoads (pp. 142, 143); control of black spot (*Phoma destructiva*) of tomatoes, by W. B. Tisdale and S. Hawkins (pp. 143, 144); strawberry wilt or crown rot, by Brooks (pp. 144, 145); stem-end rot of citrus caused by *Phomopsis citri*, by Kuntz (pp. 145, 146); decays of citrus fruits in storage, by Tisdale and E. West (pp. 146, 147); spraying requirements for control of grape diseases, by Loucks (pp. 147, 148); downy mildew or blue mold of tobacco, by L. O. Gratz (pp. 151, 152); the powdery mildew and the so-called yellowing disease of beans, early blight and bacterial spot of celery, early and late blight of potatoes, leaf blight of carrots, virus diseases of potatoes, and *Phytophthora* blight of peppers, by H. H. Wedgworth (pp. 199-202); and varietal resistance to sugarcane mosaic and control of damping-off of sugarcane seedlings, by B. A. Bourne (pp. 207, 208).

[Plant disease studies by the Georgia Station] (*Georgia Sta. Rpt.* 1932, pp. 34-36).—Data are reported on studies of tomato wilt, pepper fruit rots, peanut leaf spot, the advantages of planting shelled peanuts, breeding peanuts for disease resistance, winter injury to peaches, downy mildew of cantaloups, and the control of tomato diseases in the seed bed.

[Plant disease studies in Kansas] (*Kansas Sta. Bien. Rpt.* 1931-32, pp. 85-88, 89, 123, 124).—Data are reported as to oat smut; wheat bunt, flag smut,

and foot rot; *Helminthosporium* foot rot; resistance to corn diseases and seed treatment for their control; the finding of 5 physiologic forms of *Sphacelotheca sorghi* and 2 forms of *S. cruenta*; a new disease of milo; *Rhizoctonia solani* and the relative efficiency of various fungicides for its control; sweetpotato stem rot control; resistance of winter wheat to leaf rust; and bacterial wilt of alfalfa.

[Plant disease studies in Minnesota] (*Minnesota Sta. Rpt. 1932, pp. 13, 14, 15, 16, 17, 24, 25, 33*).—Data are reported on the finding of a bacterium antibiotic to *Ustilago zeae*, by R. H. Bamberg (pp. 13, 14); the antibiosis of certain bacteria to smuts and some other fungi, by D. E. Johnson (pp. 14, 15); hybridization and segregation in the oat smuts, by C. S. Holton (pp. 16, 17); the genetics of *U. zeae*, by J. J. Christensen (pp. 24, 25); and diseases of peonies, by L. Doadall (p. 33).

[Plant disease studies in New Mexico] (*New Mexico Sta. Rpt. 1932, pp. 38, 42, 43, 46, 47, 68, fig. 1*).—Data are reported on wilt of chili peppers, apple measles, chlorosis, root rot, and tomato diseases.

[Reports of the Dominion botanist for the years 1928, 1929, and 1930], H. T. GÜSSOW ET AL. (*Canada Expt. Farms, Div. Bot. Rpts. 1928, pp. 242, figs. 51; 1929, pp. 234, figs. 67; 1930, pp. 185, figs. 32*).—These reports preserve the general form outlined in the report for 1927 (E.S.R., 64, p. 144), adding data regarding plant disease studies for the respective years.

Control methods for diseases of cereal, forage, and fibre crops, H. T. GÜSSOW (*Canada Dept. Agr. Pam. 123, n. ser. (1930), pp. 15*).—This pamphlet is intended to summarize the present knowledge regarding plant disease control methods comprising exclusion, eradication, seed selection, seed treatment, dusting and spraying, cultural methods, sanitation, and use of disease-resistant varieties so far as applicable to wheat, oats, barley, rye, corn, millet, flax, sunflower, alfalfa, sweetclover, and common clover.

Report from the mycological department, E. S. SALMON and W. M. WARE (*Jour. Southeast. Agr. Col., Wye, Kent, No. 27 (1930), pp. 87-96*).—This report includes investigations relating to apple scab, and to hop powdery mildew, downy mildew, nettle head, chlorotic disease, and mosaic.

II. The inheritance of resistance to *Puccinia graminis tritici* in crosses between varieties of *Triticum vulgare*, K. W. NEATBY and C. H. GOULDEN (*Sci. Agr., 10 (1930), No. 6, pp. 389-404, figs. 5*).—In a continuation of the account previously noted (E.S.R., 66, p. 440), data are presented on the inheritance of resistance to stem rust in the field, 11 different crosses being included in the study.

The relation between stem rust infection and the yield of wheat, C. H. GOULDEN and F. J. GREANEY (*Sci. Agr., 10 (1930), No. 6, pp. 405-410, figs. 3*).—After experiments controlling the amounts of rust in Marquis wheat by varying the intervals and rates of applications using sulfur dust, the resulting yields were correlated with the rust percentages. The results from two such experiments are summarized in the form of correlation coefficients and regression equations.

In one experiment each 10 percent of rust reduced yield approximately 6.8 percent. In the other, 10 percent rust reduced yield 9.7 percent. In both experiments the regression of yield on percentage of rust was linear, indicating that uniform increases in rust result in uniform reductions in yield.

Field studies of take-all in Saskatchewan, R. C. RUSSELL (*Sci. Agr., 10 (1930), No. 10, pp. 654-668, figs. 6*).—Wheat take-all (*Ophiobolus graminis*) is said to have been first reported as in Canada from Saskatchewan in 1923, and to be now distributed in certain districts to an injurious but fluctuating

extent. A method is given of distinguishing this from other wheat rots which are present in Saskatchewan. Systematic field surveys from 1924 to 1929 have indicated that simple crop rotations satisfactorily control the disease.

Etiology of the bacterial diseases of beans in Bulgaria [trans. title], I. KHR. KOVACHEVSKI (I. KOVACHEVSKY) (*God. Sofisk. Univ., Agron. Fakult. (Ann. Univ. Sofia, Facult. Agron.)*, 7 (1928-29), pp. 429-444; *Eng. abs.*, p 444).—The common field bean, so widely grown in Bulgaria as to constitute one of the important crops, has become unprofitable despite favorable soil and climatic conditions, on account of severe annual losses due to the bacterial diseases blight and wilt caused by *Phytophthora phaseoli* and *P. flaccumfaciens*, both widely distributed. No native bean is immune to either disease organism. "Only the pea bean (oblets) show a relative resistance to *P. phaseoli*." Both organisms resist dry heat. The infection persists in seed dried at 52° C. for 20 hours, afterwards kept at 75° for 20 hours, and then at 85° for from 3 to 5 hours. This treatment materially impairs germinability.

Some diseases of cabbage and other crucifers in Florida, G. F. WEBER (*Florida Sta. Bul.* 256 (1932), pp. 62, figs. 47).—Various diseases which cause important losses in Florida to economic members of the crucifer family are described, particularly with reference to the plant most often and most severely attacked. Methods of control are outlined wherever such is possible. In addition there is presented a list of crucifer diseases not found in Florida and of certain physiological troubles found occasionally. Methods of seed treatment are discussed in detail.

Infection of corn plants by *Physoderma zeae-maydis* Shaw, A. H. EDDINS (*Jour. Agr. Res. [U.S.]*, 46 (1933), No. 3, pp. 241-253, figs. 4).—All the subspecies of *Zea mays* proved susceptible to brown spot caused by *P. zeae-maydis* (E.S.R., 40, p. 846) when artificially inoculated in experiments at the Florida Experiment Station, whereas a number of other grasses failed to show infection. Brown spot was most often located on the leaf blades and sheaths of corn plants at or below the fourth node from the ground. This disease was produced most effectively in the greenhouse by injecting a water suspension of sporangia into the stalks of plants 2 to 3 ft. high at or near their growing points, and in the field by filling the upper whorl of leaves with inoculum from a hand pressure sprayer when the plants were 45 to 52 days old and 35 to 51 in. high. The reaction of inbred lines to brown spot in the greenhouse was not a true indication of their reaction under field conditions.

Infection was produced by sporangia kept in soil in test tubes buried 1 ft. deep in the ground for 3 years, kept in a bottle in the laboratory for 3 years, remaining in leaf sheaths exposed to weather for 2 years, and by sporangia taken from diseased areas in green leaf sheaths. Eleven days from inoculation was the minimum time required for sporangia to develop in greenhouse plants, and 16 days in the field. Brown spot developed more in the wet season of 1930 than in the dry season of 1931. Varieties and inbred lines of corn were found to differ in susceptibility to brown spot.

The downy mildew of the hop in British Columbia, W. NEWTON and C. YARWOOD (*Sci. Agr.*, 10 (1930), No. 8, pp. 508-512).—Hop downy mildew (*Pseudoperonospora humuli*), first observed in British Columbia in the spring of 1928, became in that year epidemic in all the commercial hopyards of Sardis, Sumas, and Agassiz, and on the escaped hops at long distances. Losses due to infection of bines and cones ran as high as 50 percent. The disease is discussed as regards symptoms, mode of infection, artificial infection experiments, and resistance of species and varieties.

Young leaves proved more susceptible than old. Uninjured leaves were infected through the lower surface, injuring leaves through either. The common nettle of British Columbia, *Urtica lyallii*, is immune. All commercial hop varieties except Fuggles were susceptible.

It appeared advantageous to add potassium resin soap to the Bordeaux spray used, and to employ dust only when it could be directed against damp foliage with considerable force.

Studies on the downy mildew of onions and the causal organism, *Peronospora destructor* (Berk.) Caspary, H. T. Cook (*New York Cornell Sta. Mem.* 143 (1932), pp. 40, figs. 11).—Asserted to be one of the most serious diseases of the onion, downy mildew was found to attack with equal virulence all of 53 varieties of common onion included in the tests. *Allium schoenoprasum* (chives) was added to the seven species previously recorded as susceptible. Onion plants were observed to be attacked at any stage in their existence, and measurements showed that bulbs are considerably stunted by the disease, which is favored by abundant moisture and relatively low temperature. Onions became diseased as early and as frequently on fresh as on old soil. The first diseased plants were found scattered throughout the fields.

Of the four sources of primary inoculum, namely, systemically infected plants, infested soil, infested seed, and infected seed, evidence indicated that mycelium in the seed is an important agent. With respect to temperature, the fungus was found to fruit over a wide range. Water on the leaves was found essential to the formation of conidiophores and conidia. Of various media, lake water was most satisfactory for spore germination, which occurred from 3° to 27° C. with an optimum at 11° (51.8° F.). The incubation period was about 11 to 15 days.

The field application of fungicides was found unpractical and of dubious value. The necessity of continuous treatment from seedling stage to maturity rendered protection of prohibitive cost. The more practical means of control is believed to lie in the exclusion of the fungus, that is, the use of disease-free seed and sets and avoiding the introduction of soil from infested fields on tools or on transplants. The destruction of onion refuse and the rotation of crops are also deemed advisable.

Prevention of blight in seed potatoes, T. SMALL (*Nature [London]*, 130 (1932), No. 3279, p. 367).—It is stated that in Jersey, Channel Islands, where seed potatoes are usually dug while the haulms are still green, the presence of *Phytophthora infestans* on the foliage may occasion serious losses owing to the fall of spores on the tubers when so exposed. Losses of from 50 to 75 percent are not uncommon, but experimentation carried out at the States Experimental Station, Glenham, is said to have shown that such loss may be almost entirely annulled by twice dipping the seed tubers soon after digging in 1 percent formalin, or in a mixture of copper sulfate and caustic soda solution (4:1.25:40), which does not impair sprouting.

Potato canker and its control [trans. title], T. J. HINTIKKA (*Maataloustiet. Aikakausk. [Helsinki]*, 1 (1929), No. 1-2, pp. 49-59; *Ger. abst.*, p. 59).—The results obtained in this work led to the conclusion that soil disinfection measures employing poisons to destroy the resting spores of *Synchytrium endobioticum* causing potato canker cannot be relied upon to be effective, but that resort must be had to the aid of physical measures. International action is considered justifiable and necessary in view of the extension of the pest to many countries.

Psyllid yellows of the potato, B. L. RICHARDS and H. L. BLOOD (*Jour. Agr. Res. [U.S.]*, 46 (1933), No. 3, pp. 189-216, figs. 7).—The symptoms of psyllid

yellow (E.S.R., 65, p. 238) under ordinary summer light intensity, as studied at the Utah Experiment Station in cooperation with the U.S. Department of Agriculture, include yellowing, basal leaf rolling, and purpling of the younger leaves; yellowing and rolling of older leaves; nodal enlargement; increased leaf axillary angle; aerial tuberization and shoot proliferation; apical rosetting; excessive underground tuberization; and inhibition of the rest period. Under reduced light intensity, basal, marginal, and interveinal yellowing of the leaflets is pronounced. The purpling and leaf rolling are greatly reduced.

The disease was found to be caused by the feeding of nymphs of the tomato psyllid (*Paratrioza cockerelli* Sulc.) (E.S.R., 66, p. 555). Feeding adult psyllids failed to induce the disease in numbers up to 1,000 per plant, whereas as few as three to five nymphs frequently induced the disease, although uniformity of symptom expression required approximately 15-30 insects. Continuous feeding of the insects appears to be necessary to full expression of the disease. Recovery following the removal of the insects was observed in the greenhouse and in the field except where the disease development progressed to the point of initiating degeneracy. *P. cockerelli* appears to be the only insect capable of inducing the disease in the potato and related plants. Attempts to transmit psyllid yellows artificially failed. Under Utah conditions the disease does not appear to be transmitted from one generation to another through the tuber.

In preliminary tests, nymphs of *P. cockerelli* were not separated from the infective principle by hatching eggs on healthy potato leaves in petri dishes. The exact nature of the disease-inducing principle remained unknown. The virus theory of the etiology of the disease seemed questionable, and the possible existence of a toxic substance injected into the plant during feeding of the nymphs is suggested. The small size, ease of dissemination, prolific fecundity, apparent wide-spread distribution, and wide host range including common perennial *Solanums* are deemed vital factors in the epidemiology of the disease.

Important diseases of rice crop in Japan. S. L. KUWANA (*Proc. 4. Pacific Sci. Cong., Java, 1929, vol. 4, pp. 203-207*).—Rice disease organisms listed with indication as to forms, favoring conditions (including carriers), susceptibility, and prevention or treatment include *Piricularia oryzae*, *Helminthosporium oryzae*, *Pseudomonas oryzae*, *Hypochnus sasakii*, and *Sclerotium oryzae*. A rice virus disease called "ine no ishiku byo" occurs in the nursery beds and fields while the rice is young.

The "mentek" disease of rice. P. VAN DER ELST (*Proc. 4. Pacific Sci. Cong., Java, 1929, vol. 4, pp. 329-331*).—This disease, considered to be by far the most important of irrigated rice in Java, and supposed to be identical with imoci in Japan, ufra in India, brusone in Italy, and rust in the United States, is said to be nonparasitic, though it may be combined with attacks by fungi or pests. It is supposed to be a physiological trouble due to more or less abrupt shortage of available nutritive factors in the soil or inability of the root system to absorb properly, or to both of these causes.

Notes on gumming disease of sugar cane. J. L. ILLINGWORTH ([*Bridge-town*], Barbados: [Govt.], 1930, pp. [2]+12).—This report of special observations on gumming disease in the Leeward Islands, particularly Antigua, includes an account of work done jointly by F. H. S. Warneford and the author, and partly by Illingworth alone. It is said to cover the progress up to October, 1929, and in addition to present a general account of the disease.

Observations regarding the gumming disease in the cane Ba. 11569 as regards the 1929 crop suggest that the marked incidence might be due to the conditions resulting from the hurricane of September 12, 1928, considered as very favorable to the gumming causal organism, *Bacterium vascularum*. Observations on

young ratoon canes indicate that, while leaf symptoms are becoming general in well grown fields, stem gumming has by no means reached its maximum. The diminution of infection in second ratoons seems an important point still to be investigated.

Changes induced in cells of sugar cane by mosaic, J. DUFRENOY (*Proc. 4. Pacific Sci. Cong., Java, 1929, vol. 4, pp. 25-27, figs. 2*).—The mosaic-induced changes in sugarcane cells here briefly described extend to the mitochondria, which are said to be easily demonstrated. Many differentiate into amyloplasts, developing starch grains.

Effects of formaldehyde on *Ceratostomella fimbriata* and the sweetpotato, R. F. POOLE (*Jour. Agr. Res. [U.S.], 46 (1933), No. 3, pp. 281-290, figs. 4*).—According to a study of the effects of different strengths of formaldehyde used for various periods in treating the black-rot fungus (*C. fimbriata*) and the sweetpotato, made at the North Carolina Experiment Station, formaldehyde is neither practical nor satisfactory as a disinfectant for sweetpotatoes, and there appears to be no safe strength and length of formaldehyde treatment for the crop. Spores of *C. fimbriata* were controlled in formaldehyde containing 40 percent gas after 14 minutes in a strength of 1-25, 40 minutes in 1-50, 70 minutes in 1-75, 100 minutes in 1-100, 4 hours in 1-150, 6 hours in 1-200, and 9 hours in 1-250 strengths. However, the sweetpotato was injured severely by formaldehyde in 1-25, 1-50, 1-75, 1-100, and 1-150 strengths even at short exposures that did not kill the spores. Treatments for 4 hours in 1-200, 1-250, and 1-300 dilutions did not control the fungus, and caused a definite breaking down of the sweetpotato and greater susceptibility to decay from other fungi. Sweetpotatoes injured by both chemical and water were very susceptible to *Trichoderma*, *Rhizopus*, *Penicillium*, *Fusarium*, and other organisms.

Pathology of tobacco [trans. title], E. FOEX (*Mém. Manfr. État, Tabacs—Allumettes, 6 (1930), No. 2, pp. 275-297*).—The conditions affecting the value of tobacco are herein limited to those coming under the heads teratology, traumatism, and disorders here classed as physiological.

Tomato leaf mould, T. SMALL (*Expt. and Res. Sta., Cheshunt, Herts, Ann. Rpt., 16 (1930), pp. 40-56, figs. 8*).—In experimentation to control tomato leaf mold (*Cladosporium fulvum*) with fungicides and fumigants, most of the sprays gave better advantage with Agral 1 than when saponin was used as a spreader. Effective control on pot plants was obtained with ammonium copper carbonate, colloidal sulfur A, and salicylanilide. Ammonium copper carbonate was also useful to spray diseased crops. Control in laboratory experiments was secured by use of the fumigants ethylene dibromide, quinone, and thymol, and in a small glasshouse by quinone. Sulfur fumigation protected only the upper leaf surface, though infection occurred on either side.

Large, empty glasshouses may be practically freed from infection by use of formaldehyde or sulfur dioxide. The relation is shown of leaf mold to environmental conditions in case of commercial nurseries.

The minimum, optimum, and maximum temperatures for spore germination are respectively below 38° F., from 72° to 77°, and 89°. The germ tubes can withstand considerable dry periods. The thermal death point of the spores is 115°. Spores on diseased leaves are not killed by exposure to high temperatures on several successive days.

Mosaic disease of the tomato, W. F. BEWLEY and W. CORBETT (*Expt. and Res. Sta., Cheshunt, Herts, Ann. Rpt., 16 (1930), pp. 56-62*).—Of the two main types of mosaic herein recognized, so-called ordinary mosaic is described as typified by the mildness of its symptoms; so-called aucuba or yellow mosaic by its intense yellow color, the yellow, orange, or silver blotches on the fruits, and the frequent severe crippling of the plants.

Experiments since 1924 have shown that when aucuba mosaic of tomato is transmitted to tobacco by inoculation with the crushed tissue or filtered virus, a violent and progressive necrosis results. When juice of this tobacco necrotic tissue is inoculated back into tomato, aucuba symptoms develop, an occasional plant showing symptoms typical of stripe disease. Inoculation experiments are described in some detail.

Physiological investigations of mosaic disease in the tomato, B. D. BOLAS (*Egypt. and Res. Sta., Cheshunt, Herts, Ann. Rpt., 16 (1930), pp. 62-67*).—This is a progress report, in which the results are "to be regarded as indicating the relative importance of certain lines of work and not as completed researches."

The control of apple scab, I, II (*Jour. Southeast. Agr. Col., Wye, Kent, No. 27 (1930), pp. 186-194, figs. 4; 195-201, fig. 1*).—Two separate two-variety tests are recorded.

I. Bramley's Seedling and Newton Wonder, N. B. Bagenal, W. Goodwin, E. S. Salmon, and W. M. Ware.—Bramley Seedling gave in 1924 53 per cent of scab-free apples when sprayed with Bordeaux mixture three times, and with two sprayings 37 and 27 percent; with lime-sulfur three times, 32 and 25 percent, and twice, no crop; lime-sulfur plus lead arsenate three times, 52 per cent; and with the control 4 percent of scab-free apples. In 1925 Bramley Seedling when sprayed with Bordeaux mixture three times, gave 64 and 54 percent of scab-free apples, and twice 53 and 49 percent; with lime-sulfur three times, 61 and 51 percent, and twice, 60 and 39 percent; with lime-sulfur plus lead arsenate three times, 57 and 49 percent, and twice, 52 and 48 percent. The controls gave 38 and 30 percent of scab-free apples.

Newton Wonder in 1925 sprayed with Bordeaux mixture three times gave 89 and 83 percent of scab-free apples, and twice, 75 and 74 percent; with lime-sulfur three times, 88 and 84 percent, and twice, 89 and 87 percent; lime-sulfur plus lead arsenate three times, 87 and 83 percent, and twice, 87 and 69 percent; and the control, 78 and 68 percent of scab-free apples.

With both varieties, except one plat in 1924, additions of lead arsenate did not increase fungicidal value. In both seasons lime-sulfur caused scorching, with occasional leaf fall, on Newton Wonder apples. On this variety also lime-sulfur plus lead arsenate caused scorching and sometimes severe leaf fall. No scorching appeared on Bramley Seedling due to lime-sulfur or lime-sulfur plus lead arsenate. On both varieties in 1925 lime-sulfur gave almost as good control of scab as did Bordeaux mixture.

II. Allington Pippin and Newton Wonder, W. Goodwin, E. S. Salmon, and W. M. Ware.—Allington Pippin trees sprayed with Bordeaux mixture three times gave 87 percent of scab-free apples; when sprayed at the pink-bud stage with Bordeaux mixture followed with lime-sulfur 1:60, 92 percent of scab-free apples; and the controls gave 20, 20, and 30 percent of scab-free apples.

Newton Wonder trees sprayed with Bordeaux mixture three times gave 74 percent of scab-free apples; spraying at the pink-bud stage with Bordeaux mixture with one postblossom application of lime-sulfur (under atypical conditions described) gave 49 percent. Control apple trees showed 32, 14, and 17 percent of clean apples.

Lime-sulfur 1:60 immediately after petal fall caused leaf fall on Newton Wonder, but caused no damage to Allington Pippin apples. Two postblossom applications of lime-sulfur following a preblossom application of Bordeaux mixture gave no better finish to Allington Pippin apples than did three applications of Bordeaux mixture, which caused no russetting of commercial importance to Allington Pippin or Newton Wonder.

Apple-rot fungi in the overseas transport and marketing of New Zealand apples. M. N. KIDD (*New Zeal. Jour. Sci. and Technol.*, 11 (1929), No. 1, pp. 30-32, fig. 1).—Experimentation during 1928, constituting what is considered a fairly representative test as regards varieties (Cox Orange Pippin, Jonathan, and Sturmer Pippin), localities, and shipping conditions, is described in connection with tabulations and graphical representations.

The greatest loss was caused in the case of Cox Orange Pippin by *Diaporthe perniciosa* and in the case of Jonathan and Sturmer Pippin by *Physalospora cydoniae*, though the difference may be attributed partly to locality. The spores of the causal fungi supposedly came originally from the orchard, where some trees are seriously damaged by fungi, particularly by the two above named, though also by others, as *Glomerella cingulata*. Particular interest attaches to the presence of certain fungi not hitherto recorded for New Zealand, as *D. perniciosa* and *Fusarium fructigenum*. Wound and stem-end infection predominate. A case of wastage in apples still green, due to stem-end infection with *Sphacopsis malorum*, is reported.

A new plum disease [trans. title], M. BERGAMASCHI (*Atti Ist. Bot. R. Univ., Pavia*, 4 ser., 2 (1930), pp. 89-92, figs. 2; *Latin abs.*, p. 92).—This brief preliminary note describes a disease of *Prunus domestica*, said to be new and to be caused by the parasitic action of *Microstroma tonellianum*, which has been obtained from plum leaves.

The defoliation of gooseberries by sulphur-containing sprays. H. MARTIN (*Jour. Southeast. Agr. Col., Wye, Kent*, No. 27 (1930), pp. 182-185).—The abnormal leaf cast which occurs with certain gooseberry varieties a few days after the application of lime-sulfur to control American gooseberry mildew (*Sphaerotheca mors-uvae*) is herein dealt with, more particularly in case of the variety Leveller. This is said to suffer defoliation when sprayed with 1:60 lime-sulfur, 3 percent dry-mix sulfur-lime, or 0.4 percent Ialine colloidal sulfur (with 0.5 percent soft soap). The amount of leaf fall was not diminished by the addition to the lime-sulfur of aluminum sulfate.

These experiments did not confirm the view that the constituents of lime-sulfur causing defoliation are the soluble sulfides. The results suggest that elementary sulfur is the cause of the defoliation.

The present status of the question of the nematode diseases of coffee [trans. title], W. BALLY and G. A. REYDON (*Arch. Koffiecult. Nederland. Indië*, 5 (1931), No. 2, pp. 23-216, figs. 46; *Eng. abs.*, pp. 202-210).—This account comprises an introductory discussion of coffee nematode diseases, symptoms, methods of research, classification of the organisms according to their significance in this connection, host and parasite relations, occurrence (distribution) of the nematodes, preventive or remedial measures, and a list of relevant literature.

A table is given, indicating descriptively only the nematodes described in these chapters as regularly met with in the examination of coffee roots. This account includes, as parasitic and noxious, *Tylenchus coffeae* (*T. penetrans* ?) and *T. similis* (*T. acutocaudatus* and *T. biformis*); as parasitic but usually nonnoxious, *Caconema radiculicola* (*Heterodera radiculicola*) and *Paratylenchus besseki* n. sp.; as doubtful, *T. procerus* n. sp., *Tylenchorhynchus robustus* (*Tylenchus robustus* and *Tylenchorhynchus robustus brevicaudatus*), *T. robustus erythrae* (*Tylenchus erythrae* and *Tylenchorhynchus robustus pseudorobustus*), *Aphelenchus parietinus* (*A. coffeae*), and *Paraphelenchus maupasi* (*A. agricola*); as secondary, *Dorylaimus javanicus*, *D. zimmermanni* n. sp., *D. menzeli* n. sp., *Cephalobus persegnis brevicaudatus* (*C. brevicaudatus*), *C. longicaudatus*, *Rhabditis* sp. (*R. coffeae affinis* and *R. coffeae* ?), and

Diploscapter coronata (*R. coronata* and *R. bicornis*); and, as predacious against other nematodes, *Mononchus* sp. (*M. trichurus affinis*).

Studies on septorioses of plants, II—IV (*Mem. Col. Agr., Kyoto Imp. Univ., No. 13* (1931), pp. 1-40, pls. 5, figs. 10).—Three additional sections of the study previously noted (E.S.R., 61, p. 654) appear below.

II. *Septoria azaleae* Voglino causing the brown-spot disease of the cultivated azaleas in Japan, T. Hemmi and S. Kurata (pp. 1-22).—The authors note the occurrence and seriousness of a disease of cultivated azaleas near Kyoto, determined by them as due to *S. azaleae*. This disease appears first in early autumn on the leaves, commonly in the form of brown spots spreading with the approach of cold weather (from December to March), often causing such loss of leaves as to result in extreme weakness to the plant. The spots differ from those described by Europeans as due to *S. azaleae*. The present authors have collected diseased leaves of *Rhododendron obtusum* showing brown patches said to be similar to those described in the European account. In the present paper the morphological as well as the cultural characters of the causal fungus are presented. The most favorable liquid or agar medium proved to be potato decoction or nutrient agar with peptone. Vigorous growth occurs from 16° to 28° C., the best in liquid media at 24°. Inoculation experiments proved the pathogenicity on agar medium.

III. *On Septoria callistephi* Gloyer pathogenic on the China aster, H. Nakamura (pp. 23-32).—*S. callistephi* is widely distributed and destructive in Japan as a leaf blight of the cultivated China-aster (*Callistephus chinensis*). Occasionally the leafstalk, calyx, and flower stalk are attacked. The fungus grows favorably both on agar and on liquid media, the favorable temperature for mycelial growth being from 20° to 28°. Inoculation of the host plant with spores produced on soy agar proved successful.

IV. *New or noteworthy species of Septoria found in Japan*, S. Hirayama (pp. 33-40).—The author contributes to this series the results of his investigations as regards hitherto unreported species, with descriptions of *S. abeliceae* n. sp., *S. aparines*, *S. asteromoca-savaticrin* n. sp., *S. bupleuri*, *S. crepidis*, *S. ecliptae* n. sp., *S. erigerontis*, *S. glechomae* n. sp., *S. patriniae*, and *S. vilarsiae* on leaves, respectively, of *Abelica hirta*, *Galium strigosum*, *Asteromoca savatieri*, *Bupleurum falcatum*, *Crepis japonica*, *Eclipta alba*, *Erigeron annuus*, *Glechoma hederacea*, *Patrinia villosa*, and *Limnanthemum nymphoides japonica*.

ECONOMIC ZOOLOGY—ENTOMOLOGY

Second International Conference and Colonial Congress on the Rat and the Plague, 1931, edited by G. PETIT (*2. Conférence Internationale et Congrès Colonial du Rat et de la Peste, Paris, 1931. Paris: Vigot Bros., 1932, pp. 650, figs. [124]*).—The proceedings of the second conference (E.S.R., 67, p. 420), held in Paris, October 7-12, 1931, here reported, deal with the biology of the rat, its parasites and relation to the transmission of the plague disease of man.

Making sulfonated linseed oil for rabbit and mouse repellent, R. B. HARVEY (*Minn. Hort.*, 59 (1931), No. 9, pp. 205, 215, figs. 2).—In tests made for the protection of apple and plum trees against rabbits, a mixture consisting of sulfur one part and linseed oil nine parts, which upon heating forms a sulfonated oil of a rubbery consistency, has been found to furnish effective protection. Tested on a block of 1,200 apple and plum trees in a locality infested with rabbits, it appeared to be a good repellent. Tested with rabbits confined in a wire enclosure and given nothing else to eat, the control trees were first attacked, followed by those treated with blood, then concentrated

lime-sulfur, the sulfonated oil protected trees being attacked last and then only limbs being nibbled.

Portraits of New England birds, L. A. FURTES and A. BROOKS ([*Boston*]: *State*, 1932, pp. VI, pls. 93).—This is a collection of the colored plates previously referred to (E.S.R., 68, p. 635). Changes have been made in the common names of some of the birds illustrated to conform with the last edition of the Check-List of North American Birds (E.S.R., 66, p. 845).

Birds of the Battle River region, with notes on their present status, migration, food habits, and economic value, F. L. FARLEY (*Edmonton, Alta.*: *Inst. Appl. Art*, 1932, pp. 85, figs. 14).—Following an introduction (pp. 3-13), part 2 consists of notes on 238 birds occurring in central Alberta (pp. 14-59). Supplementary information in part 3 (pp. 60-82) gives tables showing the average date of arrival of spring birds in the vicinity of Camrose, Alta., from 1907 to 1931, last date on which birds were recorded there in the fall of 1931, and spring arrival dates during the past 40 years of three well-known summer-resident birds in central Alberta.

South China birds, H. R. and J. C. CALDWELL (*Shanghai: Hester May Vanderburgh*, 1931, pp. [14]+447, pls. 38).—This work is described as a complete, popular, and scientific account of nearly 550 forms of birds found in Fukien, Kwangung, Kiangsi, Kiangsu, and Chekiang Provinces, China. It includes six colored plates from drawings by A. Allison.

The birds of Nippon, Vol. I, pt. 1, PRINCE TAKA-TSUKASA (*London: H. F. & G. Witherby; Tokyo: Yokendo*, 1932, vol. 1, pt. 1, pp. IV+70, pls. 10, figs. 3).—In this first part of a work on the birds occurring in the Japanese possessions, a brief introduction (pp. I-IV) is followed by an account of the galline birds.

Australian finches in bush and aviary, N. W. CAYLEY (*Sydney: Angus & Robertson*, 1932, pp. [XIX]+256, pls. [21], figs. 31).—This account of the finches in Australia includes chapters on Among the Finches in Their Natural Haunts in Northern Australia, by E. W. Jones (pp. 225-228); General Hints on Housing, by F. Buckle (pp. 229-237); Good Health, by L. J. Clendinnen (pp. 238-241); and Notes on the Commoner Ailments of Cage-Birds, by E. A. D'Ombraim (pp. 242-250). The work is illustrated by 10 colored plates of finches prepared by the author.

Analyses of the stomach contents of two species of Idaho lizards, with special reference to the Formicidae, A. C. COLE, JR. (*Ann. Ent. Soc. Amer.*, 25 (1932), No. 3, pp. 638-640).—A table is given reporting upon the stomach contents of 25 specimens each of *Sceloporus graciosus graciosus* Baird and Girard and *Uta lewis* Baird and Girard taken at random. A second table reports upon the numbers of the 13 species of Formicidae removed from the stomachs of these lizards.

Laboratory and field manual of economic entomology, J. R. EYER (*Ann Arbor, Mich.: Edwards Bros.*, 1932, pp. [4]+132, figs. 12).—Part 1 of this mimeographed laboratory and field manual deals with insect anatomy, taxonomy, and metamorphosis (pp. 1-37), part 2 with control measures against insects (pp. 38-71), part 3 with laboratory studies of the literature of economic entomology and the preparation of an entomological thesis (pp. 72-78), and part 4 with field and laboratory studies of the more common insects injurious to crops (pp. 79-132).

The effect of radio waves on internal temperatures of certain insects, T. J. HEADLEE (*Jour. Econ. Ent.*, 26 (1933), No. 2, pp. 313-319, fig. 1).—Contributing from the New Jersey Experiment Stations, the author points out that in the production of high temperature lethal effects on certain insects subjected to lines of force in an electrostatic field it is a matter of prime importance

that internal heat production should be as rapid as possible. It has been found that this speeding up of heat production can be accomplished through increasing the strength of the electrostatic field.

A list is given of 15 references to the literature.

Ecological studies in relation to the distribution and abundance of economic pests. H. L. SWEETMAN (*Jour. Econ. Ent.*, 26 (1933), No. 2, pp. 320-325).—The author considers the methods and technics that can be used to obtain information from which forecasts of establishment, abundance, dispersal, control, and eradication of insect pests can be made. Reference is also made to predictions of abundance and dispersal of several insects that fit present known conditions. Controlled laboratory experiments where climate is simulated and quantitative data collected under natural conditions, together with correlative studies, are considered to afford a good means of analyzing and forecasting insect outbreaks. By means of such ecological investigations quarantine regulations and control and eradication measures could probably be made more effective.

A list is given of 36 references to the literature.

Plant pest handbook for Connecticut. I, Insects. W. E. BRITTON (*Connecticut State Sta. Bul.* 344 (1933), pp. 65-182+XI-XVIII, figs. 88).—Following a brief account of insects and their injuries to plants (pp. 69, 70), the principal insect pests of cultivated plants are considered, brief notes being given on each, together with illustrations of the pests and in many cases the nature of their injury, the arrangement being alphabetical and according to the plants attacked. The handbook concludes with a list of formulas for insecticides and an index to the pests considered. It is based upon and replaces the spray calendar, the last revised edition of which as Bulletin 271 was issued in 1926 (E.S.R., 54, p. 642).

[**Report of work in entomology in Connecticut**] (*Connecticut State Sta. Bul.* 347 (1933), pp. 275-277).—This is a brief report of work under way with economic insects (E.S.R., 67, p. 559), including parasites of the oriental fruit moth, control of the Mexican bean beetle, the European pine shoot moth, potato flea beetle, gipsy moth, and European corn borer.

[**Report of work in Florida with economic insects, nematodes, and rodents**] (*Florida Sta. Rpt.* 1932, pp. 69-91, 191-195, 203-205).—The work reported upon (E.S.R., 67, p. 559) includes that with the Florida flower thrips and root knot, both by J. R. Watson; introduction and study of *Cryptolaemus montrouzieri* and *Leis conformis* lady beetles, by Watson and W. L. Thompson; lime-sulfur as a control for the purple scale, the control of the American grasshopper by nonarsenical poisons, rose chafers (*Macrodactylus angustatus*), and dry wood termites (*Necoterms castaneus*), all by Thompson; the bean jussid (officially known as the potato leafhopper), by A. N. Tissot; green citrus aphid (*Aphis spiraeicola*), by Watson, Thompson, and Tissot; control of the pecan nut case bearer and its parasites, control of the walnut case bearer, and observations of the hickory shuck worm, the black hickory aphid (*Melanocallis caryaefoliae* (Davis)), the bark aphid (*Longistigma caryae* (Harr.)), mites (*Tetranychus* sp. ?), pecan cigar case bearer, twig girdler, walnut caterpillar, fall webworm, grape colaspis, and the blueberry fruit worm (*Acrobasis caccinii* (Riley)), considered under the heading of control of fruit and nut crop insects, by F. W. Walker; the larger plant bugs on citrus, pecan, and truck crops, including the southern green stinkbug and the leaf-footed bug and their natural enemies, by H. E. Bratley; insects of ornamentals, particularly the beet armyworm, by J. W. Wilson; insects and other animal pests of watermelons, including nematodes and field mice, by C. C. Goff; control of the cotton boll

weevil, by E. F. Grossman and P. W. Calhoun; and the granulate cutworm, the black cutworm, and *Cirphis latiuscula*, bean jassids (the potato leafhopper and others), aphids, the velvetbean caterpillar, cucumber beetles (*Diabrotica* spp.), the prevalence and control of the sugarcane borer in south Florida, and the prevalence and control of rodents under field and village conditions, all by R. N. Lohdell at the Everglades Substation.

[Report of work with economic insects] (*Kansas Sta. Bien. Rpt. 1931-32*, pp. 84, 89-100).—This is a report of work (E.S.R., 64, p. 852) on bee investigations, by R. L. Parker; climate and injurious insect investigations, by R. C. Smith; Hessian fly, wheat stem maggot, and the wheat straw worm, by R. H. Painter; the corn ear worm and other insects injurious to corn, by D. A. Wilbur and H. R. Bryson; the apple curculio and the strawberry leaf roller, by Parker; corn leaf aphid attacking the sorghums and wireworms and other insects attacking the roots of staple crops, both by Bryson; the pea aphid, alfalfa thrips, variegated cutworm, clover leaf weevil, and grasshopper control, by R. C. Smith; insects injurious to grasses and allied plants, by Wilbur; shade tree insects, by Parker; codling moth investigations, by P. M. Gilmer, Parker, and G. A. Dean; the resistance of sorghums, corn, and wheat to insect injury, by Painter, A. M. Brunson, and J. H. Parker; and investigations of ground squirrels and rats, by G. E. Johnson.

A summary of the population of injurious insects in Kansas for 1931, R. C. SMITH (*Jour. Kans. Ent. Soc.*, 5 (1932), No. 3, pp. 65-92, figs. 21).—This report from the Kansas Experiment Station upon the occurrence of economic insects in Kansas in 1931 is presented in part in tabular and chart form.

Montana insect pests for 1931 and 1932, A. L. STRAND (*Montana Sta. Bul.* 269 (1932), pp. 28, figs. 4).—In this twenty-fourth report of the State-entomologist of Montana (E.S.R., 64, p. 747) insect pests are considered under the headings of outlook for cutworms in 1933, grasshoppers, a new pest of wheat in Montana (*Blapstinus substriatus* Champ.), the Mormon cricket, the sugar beet webworm (officially known as the beet webworm), and fruit insects. A tabulation of insect pest correspondence for 1931-32 made up from inquiries received follows.

[Report of work in New Mexico with economic insects] (*New Mexico Sta. Rpt. 1932*, pp. 38-42, 43-46, 47, 48, 49, 51, 52, 66, figs. 4).—The work reported upon (E.S.R., 67, p. 50) includes that with codling moth sprays and baits; the giant apple root borer [*Prionus californicus* Mots.], an account of which pest by Crawford and Eyer has been noted (E.S.R., 60, p. 64); San Jose scale; grasshopper baits; nicotine tannate for control of onion thrips; psyllid yellows of potato produced by *Paratrioza cockerelli* and hopperburn produced by *Empoasca abrupta*; tomato insects; and arsenic spray residue on New Mexico apples.

[Notes on economic insects and insecticides] (*Jour. Econ. Ent.*, 26 (1933), No. 2, pp. 509-517).—The contributions presented (E.S.R., 69, p. 73) include the following: Injury to Carrot, *Daucus carota*, by *Triplaphis phaseoli* Pass.), by C. B. Cutright (p. 509); The Lesser Apple Worm (*Grapholitha prunivora* Walsh) in California, by H. H. Keifer (p. 509); *Thylocleia contractus* Mots., by C. L. Metcalf (pp. 509, 510); The Beech Scale and a Fungus [*Neotria coccinea*], by E. P. Felt, (p. 510); *Sitotroga* Production (pp. 510, 511) and Some Early Observations concerning *Trichogramma* (p. 511), both by S. E. Flanders; Worn-out Motor Oil for the Control of the San Jose Scale, by O. I. Snapp and J. R. Thomson (pp. 511, 512); Naphthalene for Midge Larvae in Tobacco Seed Beds, by B. B. Fulton (pp. 512, 513); Parasite Reared from the Elm Leaf Beetle and the Imported Willow Leaf Beetle [*Plagioderma versicolora*

Laich.], by T. H. Jones (p. 513); Decay of Apple Tissue in Storage Associated with Cherry Case Bearer [*Colcophora pruniella* Clem.] Injury, by C. L. Fluke and J. H. Lilly (pp. 513, 514); The Species of *Eumerus* on Long Island, by F. S. Blanton and F. J. Spruijt (pp. 514, 515); A Leaf Miner [Serpentine Leaf Miner] Attacking the Cultivated Onion, by H. M. Harris and H. D. Tate (pp. 515, 516); and Note on the Use of Microorganisms for the Production of Odors Attractive to the Dried Fruit Beetle, by J. D. Wildman (pp. 516, 517).

[Contributions on economic entomology] (*Ztschr. Angew. Ent.*, 19 (1932), Nos. 1, pp. 1-151, figs. 30; 2, pp. 161-311, figs. 53; 3, pp. 325-489, figs. 52; 4, pp. 497-618, figs. 50).—The contributions here presented (E.S.R., 67, p. 284) are as follows:

No. 1.—The Fluctuation of Insect Populations, by W. Zwölfer (pp. 1-21); Contributions to the Knowledge of the Morphology, Anatomy, and Biology of *Lophyrus pini* L., by G. Eliescu (pp. 22-67); A New Contact Insecticide ("For-estit"—Merck), by B. A. Marcus (pp. 68-84); The Normal Food of the Pine Spinner (*Dendrolimus pini* L.), by A. G. Lebedev and A. N. Savenkov (pp. 84-103) (E.S.R., 64, p. 543); The Epidemiology of the Pine Geometrid [*Bupalus piniarius* L.], by F. Schwerdfeger (pp. 104-129); The Pine Geometrid and Its Parasites—Their Gradation, by K. Friederichs (pp. 130-143); Two New Braconid Parasites [*Phanerotoma buchneri* and *Agathis bischoffi*] of an Entomophagous Moth Enemy [*Holcocera pulvereacea* Hump.] of the Lac Insect, by J. Fahringer (pp. 144-146); and The Biology of Beetles of the Genus *Sitona* Germ., by N. A. Grossheim,¹ abs. by L. Branumanis (pp. 147-151).

No. 2.—Contributions to the Knowledge of the Pest Fauna of Anatolia (Asia Minor)—II, On the Relation of the Grain Bug *Eurygaster integriceps* Put. to Biotic Environmental Factors, by W. Zwölfer (pp. 161-187) (E.S.R., 65, p. 852); Contributions to the Knowledge of the Morphology, Anatomy, and Biology of *Lophyrus pini* L., II, by G. Eliescu (pp. 188-206); Meteorological Observations in the Course of Control Work with the Pine Noctuid [*Panolis flammea*] in Middle Fraconia through Use of Airplane and Motor Dusters in the Spring of 1931, by R. Geiger (pp. 207-222); On the Biology of *Nemeritis canescens* Grav. (Hymen. Ophion)—I, Rearing Experiments and Ecological Observations, by I. Beling (pp. 223-249); Contributions to the Biology of Nutrition in *Hylobius abietis* L. and Investigations of the Ecology and Climatology of Its Feeding Space, by K. R. Fischer (pp. 250-277); Contributions to the Knowledge of the Biology of *Agriotes lineatus* L. and *A. obscurus* L., by R. Langenbuch (pp. 278-300); On the Biology of *Ptinus tectus* Boield., by H. F. Friederichs (pp. 301-306); and Can *Calandra granaria* L. Breed in Flour? by K. T. Andersen (pp. 307-311).

No. 3.—Contributions to the Knowledge of *Lyctus linearis* Goeze, by T. Kojima (pp. 325-356); A knowledge of the Life History, Habits, and Morphology of Cereal-Infesting Haliicidae, by H. Blunck (pp. 357-394); Studies of the Ecology and Epidemiology of the Cabbage Butterfly—I. The Influence of Temperature and Humidity upon the Development and Mortality of *Pieris brassicae* L., by H. Z. Klein (pp. 395-448); and A Decade of the Mite Disease of the Honeybee: Discovery, Investigation, and Control, by O. Morgenthaler (pp. 449-489).

No. 4.—Methods of Regulation of Temperature and Humidity, by W. Zwölfer (pp. 497-513); *Icerya purchasi* Mask. and *Novius cardinalis* Muls., a Population Study of the Fundamentals of Biological Control, by F. S. Bodenheimer (pp. 514-543); Evaluation of the Toxic Action of Insecticide Gasses by the

¹ Materials for the Study of the Genus *Sitona* Germ. [trans. title]. Trudy Mleev. Sadovo-Ogorod. Opytn. Sta. (Bul. Mleev. Hort. Expt. Sta.), No. 17 (1928), pp. 57, figs. 66.

Frequency in Pulsation of the Dorsal Vessel, by R. KIRSCHNER (pp. 544-556); **On the Biology and Technical Significance of Wood Wasps [Siricidae]**, by M. ASS and G. FUNTIKOW (pp. 557-578); **Experimental Contribution on the Biology of Mosquitoes, II**, by O. HECHT (pp. 579-607) (E.S.R., 65, p. 656); **The Rice Pyralid Problem in China [Asiatic Rice Borer and *Schoenobius bipunctifer* Walk.]**, by P. H. TSAI (pp. 608-614); **The Identification of Geometrid Pupae Found in Pine Forests**, by W. ZWÖLFER (pp. 614-617); and **Bioclimatogram**, by ZWÖLFER (pp. 617, 618).

Annual report of the entomological section for 1930-31, T. V. SUBRAMANIAM (*Mysore Dept. Agr. Rpt. 1930-31*, pp. 28-33).—This report upon the occurrence of and work with several of the more important insect enemies of crops in Mysore (E.S.R., 67, p. 286) includes an account of the mass rearing of *Trichogramma*, which has been found to parasitize the eggs of *Diacrisia obliqua* Walk., *Adisura atkinsoni* Mo., corn ear worm, *Euxoa* sp., and an unidentified moth on grasses.

[**Entomological work in Sierra Leone**], E. HARGREAVES (*Sierra Leone Dept. Agr. Ann. Rpt. 1931*, pp. 18-20).—A brief account of the occurrence of and control work with the important insects of the year.

[**Entomological work in Tanganyika Territory**] (*Tanganyika Ter. Dept. Agr. Rpt. 1931*, pp. 83-93).—The occurrence of and work with insects of economic importance in 1931 (E.S.R., 65, p. 547) is reported by A. H. RITCHIE (pp. 83-86) and W. V. HARRIS (pp. 87-93).

Pests of cotton in the Callide Valley, D. O. ATHERTON (*Queensland Agr. Jour.*, 38 (1932), No. 6, pp. 488-492).—An account of the important enemies of cotton occurring in the Callide Valley, Queensland.

[**Proceedings of the entomological section of the International Congress of Forestry Experimental Stations**] (*In Verhandlungen des Internationalen Kongresses Forstlicher Versuchsanstalten, Stockholm, 1929. Stockholm: Centraltryckeriet, 1930*, pp. 629-682, figs. 10).—This consists of 11 contributions on forest entomology that were presented at the meeting held in Stockholm in July 1929.

The composition of some commercial insecticides, fungicides, bactericides, rodenticides, and weed killers, compiled by H. J. FISHER and E. M. BAILEY (*Connecticut State Sta. Bul. 346* (1933), pp. 209-268).—This is a compilation which supplements Bulletin 300 (E.S.R., 61, p. 355).

The rotenone content of derris root, cube root, and other plant materials, H. A. JONES (*Jour. Wash. Acad. Sci.*, 23 (1933), No. 1, pp. 36-46).—The rotenone content of 45 samples of derris root tested was found to range from 0 to about 7 percent, while that of 23 samples of cube root ranged from less than 1 to about 11 percent. The average of the 31 samples of derris root analyzed by the carbon tetrachloride method was 2.5 percent rotenone, while the average for the 22 samples of cube root analyzed by this method was 5.4 percent rotenone. It is pointed out that these averages should not be considered representative of derris and cube samples in general.

Loss in toxicity of deposits of rotenone and related materials exposed to light, H. A. JONES, W. A. GERSDORFF, E. L. GOODEN, F. L. CAMPBELL, and W. N. SULLIVAN (*Jour. Econ. Ent.*, 26 (1933), No. 2, pp. 451-470, figs. 4).—This is an account of results of studies of rotenone conducted by the U.S.D.A. Bureau of Chemistry and Soils, the Bureau of Entomology cooperating, in connection with a list of 14 references to the literature.

"**Rotenone, dihydrorotenone, rotenone hydrochloride, rotenone-bentonite (1:1), rotenone-lampblack (1:1), ground derris root, and powdered derris extract were each made into a paste with water and painted heavily on weighted glass slides. After the deposits had dried, the slides were weighed**

again. One group of slides was exposed to direct sunlight for 10 days during April and May, a second group to sunlight for 20 days, a third group to arc light for 240 hours, a fourth group of the 3 pure compounds only to arc light for 480 hours, and a fifth group was kept in the dark at room temperatures. The deposits on these slides were tested against culicine mosquito larvae and goldfish to determine the percentage loss of toxicity resulting from exposure to light. In all cases the exposed deposits were decidedly less toxic than the unexposed, and with one exception the loss of toxicity increased with increasing exposure. Rotenone, rotenone-bentonite, derris root, derris extract, and rotenone hydrochloride lost more than half of their toxicity during 10 days' exposure to sunlight. Their toxicity was practically destroyed by the exposure to arc light. Since dihydrotenone lost only one fourth to one third of its toxicity during the first 10 days' exposure to sunlight, it was distinctly more resistant to detoxication during this period than rotenone. However, at the end of 20 days in sunlight and after exposure to arc light it had lost toxicity to about the same extent as rotenone.

"Lampblack markedly reduced the loss of toxicity of rotenone during the first 10 days' exposure to sunlight, and prevented further loss during the last 10 days. It also gave some protection to rotenone under arc light. Neither bentonite nor the substances occurring with rotenone in powdered derris root and derris extract protected rotenone from loss of toxicity. The unexposed powdered derris extract containing about 25 percent rotenone was as toxic to mosquito larvae as pure rotenone. It was shown that the photochemical decomposition of dry rotenone, which results in loss of its toxicity to insects and fish, does not take place in the absence of oxygen."

Accidental sodium fluoride poisoning, T. P. SHARKEY and W. M. SIMPSON (*Jour. Amer. Med. Assoc.*, 100 (1933), No. 2, pp. 97-100).—The authors report upon one fatal case and seven nonfatal cases of accidental poisoning with sodium fluoride, widely employed as an insecticide, that occurred in a hospital in Dayton, Ohio, within one month. The report emphasizes the importance of care in keeping it separate from containers used for saline solutions or baking powder.

Some factors affecting the efficiency of contact insecticides, II, III (*Contrib. Boyce Thompson Inst.*, 4 (1932), No. 1, pp. 107-117, figs. 2; 5 (1933), No. 1, pp. 115-127, figs. 4).—These parts continue the previous contribution (E.S.R., 65 p. 357).

II. *Chemical and toxicological studies of pyrethrum.* A. Hartzell and F. Wilcoxon.—A method is described for the determination of comparative toxicity to the bean aphid of samples of pyrethrum flowers without the use of a wetting agent. The average deviation between duplicate determinations made on the same day by this method was 6.4 percent kill. A loss in pyrethrin content of pyrethrum flowers was caused by heat, sunlight, ultraviolet light, and natural aging. In all cases a decrease in pyrethrin content as determined chemically corresponded to a decreased toxic effect on insects.

No lasting protection was afforded by spraying nasturtium plants with pyrethrum solutions and infesting them with the bean aphid after the plants had dried. Refluxing a pyrethrum solution in methyl alcohol for four hours did not result in a significant loss in toxicity. Pyrethrum concentrates were toxic to a number of cold-blooded animals, including species representing 10 orders of insects, when applied externally to the integument. Such concentrates were toxic even when applied locally to regions of the body far removed from vital organs. These concentrates injected into the body cavity led to almost immediate occurrence of toxic symptoms. Preliminary results indi-

cate that there is an axial gradient in susceptibility to pyrethrum when extracts are applied to the tomato worm larvae, the anterior region being most susceptible. When rose chafer adults in a moribund state from pyrethrum intoxication were exposed to a higher temperature, the processes of recovery and death were both accelerated.

The account is presented in connection with a list of 19 references to the literature.

II. *Further chemical and toxicological studies of pyrethrum*, F. Wilcoxon and A. Hartzell.—“A method is described for obtaining samples of the pyrethrins free from accompanying impurities which is simpler than methods described previously, and which does not require the conversion of the pyrethrins into a derivative and their subsequent regeneration. In the course of this work samples have been obtained differing widely in the ratio of pyrethrin I to II. Toxicity tests using these samples on *Aphis rumicis* indicated that I is far more toxic than II.”

Summer oil emulsions against the oriental fruit moth and other insects, S. W. Frost (*Jour. Econ. Ent.*, 26 (1933), No. 2, pp. 334-344, pl. 1).—In laboratory tests with 2 percent oil emulsions under severe conditions at the Pennsylvania Experiment Station, the author failed to secure as high a kill as was obtained in the work in the preceding year (*E.S.R.*, 67, p. 572). Several commercial oil emulsions were said to have been used without injury on peach and apple, and these in combination with sulfur had been used on peach and in combination with 3-3-50 Bordeaux on apple without injury. A 2 percent oil emulsion without lead arsenate gave no control of codling moth. A 5 percent oil impregnated with lead, sulfur, lime dust gave considerable reduction of oriental fruit moth injury.

Experiments with tar distillate sprays against fruit aphids and associated insects, F. Z. HARTZELL, P. J. PARROTT, and S. W. HARMAN (*Jour. Econ. Ent.*, 26 (1933), No. 2, pp. 474-480).—This is a report of field trials of tar distillate sprays conducted in a number of orchards in western New York in 1932 to determine their effects upon the trees and efficiency in controlling fruit insects.

“Four American and four European brands were used in the experiments. Concentration of tar washes in the applications on apples generally varied from 5 to 7.5 percent, although mixtures containing 2 and 3 percent were tried on a few trees. Except in the case of one plat that was sprayed very late in the fall, all applications on the apple were made in the spring not later than the gray-tip stage of the buds. On sweet cherry and pear, the mixtures contained 4 and 5 percent of the emulsions respectively.

“Control of the rosy apple aphid was secured in all trials when the concentrations of tar washes were not less than 5 percent. Lower concentrations generally proved less effective. A fall application did not give as high control as spring treatments. In practically all instances, the control of rosy apple aphid by spring applications of tar washes (not less than 5 percent) was similar to that effected by nicotine sulfate (1:800). A single experiment indicates that these materials may prove effective against the black cherry aphid. Tests with one brand indicate that in severe infestations tar distillate sprays are not as effective as lubricating oil emulsions for the control of San Jose scale. Four brands, used at 5 and 7.5 percent, appear to be very effective on oyster-shell scale. Tar washes (7.5 percent) in the tests were but slightly inferior to nicotine sulfate (1:400) in lubricating oil against the eye-spotted budmoth, while lower concentrations of the washes produced moderate control. The results with apple redbug indicate that rather low efficiencies are to be expected from tar washes (7.5 percent) when used against

this insect. One brand (5 percent) proved destructive to the eggs of pear psylla. At the concentrations used none of the materials proved injurious to the buds or wood of apple, sweet cherry, and pear during 1932."

Tests with tar distillate sprays for foliage applications, F. Z. HARTZELL (*Jour. Econ. Ent.*, 26 (1933), No. 2, pp. 480-486).—At the New York State Experiment Station tar distillates "were tested as foliage sprays on numerous varieties of apples in an effort to determine their value for codling moth and apple aphid control. Four brands of tar washes were used with standard fungicides, viz, lime-sulfur (1-40), Bordeaux mixture (4-8-100), and dry-mix sulfur and lime. In the tests on young McIntosh trees comparisons were made with untreated trees and those sprayed with each fungicide mixed with arsenate of lead. In trials on many varieties of bearing trees, comparisons were made between those of the same variety sprayed with the same fungicide in which arsenate of lead replaced tar distillates. These latter were found apparently compatible with the three fungicides.

"The results against apple aphid were irregular and contradictory, so no marked value of these materials was noted. Based on 'wormy' apples, arsenate of lead proved superior in every one of the 16 comparisons, while the same material gave better control in 15 of the 16 pairs of tests when the total codling moth injuries were considered. The problem of spray residue was not eliminated. Leaf injury, russeting, and pitting of the fruit of a number of varieties leads to the conclusion that the causes of these injuries must be determined and eliminated before much progress can be made in experimentation with tar distillate sprays for control of the codling moth."

Naphthalene as a fumigant for the immature stages of clothes moths and carpet beetles, G. W. HERRICK and G. H. GRISWOLD (*Jour. Econ. Ent.*, 26 (1933), No. 2, pp. 446-451).—The authors have found that naphthalene flakes at the rate of from 2 to 3 oz. to 5 cu. ft. proved toxic to the eggs and larvae of the webbing clothes moths when confined for a sufficient length of time in a tight trunk or in a box. Moth balls at the rate of 8 oz. to 5 cu. ft. proved toxic to the larvae of clothes moths when confined in a tight box for a considerable period of time. The results with the immature stages of carpet beetles (the black carpet beetle and the varied carpet beetle) were only partially satisfactory.

The Collembola-Symphyleona of Australia.—A preliminary account, H. WOMERSLEY (*Aust. Council Sci. and Indus. Res. Pam.* 34 (1932), pp. 47, figs. 19).—An illustrated systematic account of the Collembola of Australia, with tables for the separation of families and genera and a list of 111 references to the literature. It includes a foreword by R. J. Tillyard.

The Chrysopidae (Neuroptera) of Canada, R. C. SMITH (*Ann. Ent. Soc. Amer.*, 25 (1932), No. 3, pp. 579-600, pl. 1).—Thirty-four forms of Chrysopidae, representing four genera, are recognized, of which two are described as new.

Termites of western Mexico, S. F. LIGHT (*Calif. Univ. Pubs. Ent.*, 6 (1933), No. 5, pp. [4]+79-164, pls. 5, figs. 33).—The present paper reports upon the important systematic and faunistic results of investigations of the termites of western Mexico, involving descriptions of 12 new species and 1 new genus in addition to the 4 new species of *Amitermes* previously described (*E.S.R.*, 64, p. 750). In addition, 2 doubtful species of long standing have been rediscovered and defined, and 6 other species not previously known to exist there have been added to the Mexican fauna. A list of 34 references to the literature is included.

The use of a modified McIndoo olfactometer for the European earwig, *Forficula auricularia* (Dermap.), G. BEALL (*Ent. News*, 44 (1933), No. 1, pp.

6-10).—A report upon an attempt made during the winter of 1930-31 to test the chemotropic responses of the European earwig.

Further studies of the relative toxicity of poisons for grasshopper baits, C. H. RICHARDSON and G. A. THURBER (*Jour. Econ. Ent.*, 26 (1933), No. 2, pp. 494-499).—In work at the Iowa Experiment Station adult differential grasshoppers "were fed determined quantities of a standard bran-molasses bait which contained known concentrations of arsenious oxide, sodium fluoride, cuprous cyanide, zinc phosphide, sodium fluoaluminate, acid lead acetate, and nicotine tannate. The estimated minimum lethal dose of the first three compounds is 0.11 mg per gram of body weight, for zinc phosphide it is 0.52 mg/gram. Acid lead arsenate is much less toxic, the minimum lethal dose being approximated as 2 to 4 mg/gram; sodium fluoaluminate is evidently less toxic than acid lead arsenate. Nicotine tannate has a low but undetermined toxicity for this insect. The toxicity of some of these compounds for other insects is discussed briefly. Cuprous cyanide and zinc phosphide seem worthy of further experimental investigation."

Sodium fluosilicate as a poison against the hoppers of *Locusta migratoria migratorioides* R. & F. in Nigeria, F. D. GOUDING (*Bul. Ent. Res.*, 23 (1932), No. 4, pp. 449-461).—In combating *L. migratoria migratorioides*, sodium fluosilicate was found to be as effective as sodium arsenite in baits when used at the same concentration, namely 2.44 percent, but was slower in its action.

Another oriental mantis well established in the United States (*Tenodera angustipennis* Saussure, Orthoptera: Mantidae), F. M. JONES (*Ent. News*, 44 (1933), No. 1, pp. 1-3, pl. 1).—The mantis *T. angustipennis*, native of China, Japan, and Chosen (Korea) not hitherto recorded from the United States, is reported as having been first found in September 1930, near Vandyke, New Castle County, Del.

The food plants of the leafhoppers, R. D. BALL (*Ann. Ent. Soc. Amer.*, 25 (1932), No. 3, pp. 497-501).—The author concludes that recent additions to the knowledge of food plant relations in the leafhoppers indicate a very definite and restricted food habit for the great majority of species, the few exceptions forming the nucleus of a small group of injurious forms. While large groups are almost exclusively grass feeders, others that have been reported as grass feeders have other food habits. In general, all the members of a natural group will be found to be either grass feeders or all of them will have other food habits.

Spray tests for the white apple leafhopper, *Typhlocyba pomaria*, W. J. SCHOENE (*Jour. Econ. Ent.*, 26 (1933), No. 2, pp. 325-328).—Contributing from the Virginia Experiment Station, the author reports on spray experiments to control the second brood of the white apple leafhopper (*T. pomaria*) on apple trees, in which nicotine combined with Penetrol or summer oil was effective.

Erythroneura collected on apple with description of a new species, R. H. BEAMER (*Jour. Kans. Ent. Soc.*, 5 (1932), No. 2, pp. 62-64).—Fifteen species are recorded as taken from the apple, of which one, collected in Kansas, Arkansas, and Pennsylvania, is described as new under the name *E. dowellii*.

A review of the Nearctic species of *Macropsis* (Homoptera, Cicadellidae), E. P. BREAKEY (*Ann. Ent. Soc. Amer.*, 25 (1932), No. 4, pp. 787-844, pls. 4, figs. 3).—The author recognizes 29 species and 3 varieties of this genus of Cicadellidae as occurring in North America, none of which is known to be a pest of economic importance.

Ecological studies on aphids infesting the potato crop, W. M. DAVIES (*Bul. Ent. Res.*, 23 (1932), No. 4, pp. 535-548, fig. 1).—This is a report of ecological studies of aphids attacking potatoes in Wales, commenced in 1928. The

species studied include the green peach aphid, *Macrosiphum gei* Koch, and *Myzus pseudosolani* Theob.

The identity of the black pecan aphid, *Melanocallis caryaefoliae* (Davis), T. L. BISSELL (*Ann. Ent. Soc. Amer.*, 25 (1932), No. 4, pp. 730-735, figs. 6).—Contributing from the U.S.D.A. Bureau of Entomology and the Georgia Experiment Station, in cooperation, the author reports upon a study made of the types of *Aphis fumipennella* Fitch and *A. caryaefoliae* (Davis) in comparison with many additional species taken from pecan and other hickories. A comparison of the *A. caryaefoliae* type with aphids from hickory and pecan from several southern States has shown the black pecan aphid to be this species. *A. fumipennella* is known only from the imperfect type specimen and cannot now be placed in any genus.

Control of the black hickory aphid, F. W. WALKER (*Ga.-Fla. Pecan Growers Assoc. Proc.*, 1932, pp. 39-43).—In control work some of the best results have been obtained with nicotine sulfate 40 percent, using sulfonated oxidation products of petroleum (Penetrol) as spreader and activator. The formula giving the greatest percentage of kill of this insect for the least cost per gallon of finished spray consists of nicotine sulfate 40 percent 1:5,000 and Penetrol 1 qt. in 50 gal. 0.5 percent. In making this spray the nicotine sulfate and the Penetrol should be combined and then thoroughly mixed with about three times their volume of water before putting into the spray tank.

Five new species of *Anuraphis* and *Aphis*, A. N. TISSOT (*Fla. Ent.*, 16 (1933), No. 4, pp. 49-60, figs. 44).—Contributing from the Florida Experiment Station, the author presents descriptions of five new aphidid species, namely, *Anuraphis arundinariae* from *Arundinaria tecta*, *Anuraphis itcae* from *Itea virginica*, *A. minima* from *Prunus* spp., *Aphis astericola* from *Aster* sp., and *A. floridanae* from *Lactuca floridana*, all from Florida.

The presence of *Anuraphis persicae niger* Smith in France [trans. title], R. PUSSARD (*Bul. Soc. Ent. France*, 37 (1932), No. 7, pp. 110-113).—Notes are presented on *A. (Brachycaudus) amygdali* Buckt. and the black peach aphid, two morphologically and biologically distinct species heretofore confused.

The efficiency of tar distillate sprays in controlling San Jose scale in 1932, W. S. HOUGH (*Jour. Econ. Ent.*, 26 (1933), No. 2, pp. 470-473).—This is a report of the results obtained by the Virginia Experiment Station in the second season's experiments with sprays containing coal tar distillates of English and American origin, which were found to confirm the results of the preceding year (*E.S.R.*, 67, p. 708). The higher concentrations may give control of San Jose scale comparable to that obtained with a standard petroleum oil spray of 3 percent oil. A combination of coal tar oil and petroleum oil against aphid eggs and scale in the dormant season is suggested.

Biological study of the Coccidae of the western basin of the Mediterranean, A. BALACHOWSKY (*Étude Biologique des Coccides du Bassin Occidental de la Méditerranée*. Paris: Paul Lechevalier & Sons, 1932, pp. 214+LXXI, [figs. 68]).—Part 1 of this work reports upon a biogeographical study of the Coccidae of North Africa (pp. 11-119); part 2 deals with the factors influencing population (pp. 121-155) and part 3 with observations of parasites and parasitism of the Coccidae, including a bibliography of 14 pages (pp. 157-214); and part 4 consists of (1) a revised catalogue of the Coccidae of North Africa (Algeria, Tunisia, Morocco, Sahara), representing 169 forms (pp. I-XLIV), and (2) a preliminary list of the Coccidae of the Maritime Alps, of Var, of Bouches-du-Rhône, of the Upper Alps, of the Lower Alps, and of Corse (Corsica) (pp. XLV-LXVII).

An account of my studies in the biology of *Pieris rapae*, O. QUERCI (*Ent. Rec. and Jour. Variation*, 44 (1932), No. 12, pp. 168-176).—Observations made

of the imported cabbage worm in the vicinity of Philadelphia are reported under the headings of breeding from the eggs, temperature experiments, and life history of *P. rapae* at Philadelphia in the year 1932, and other observations.

The codling moth in New York, P. J. PARBOTT (*Jour. Econ. Ent.*, 26 (1933), No. 2, pp. 358-363).—This is a discussion of the importance of the codling moth to the apple industry of New York State and the status of spray practices.

A field and laboratory technique for toxicological studies of the codling moth, E. H. SIEGLER and F. MUNGER (*Jour. Econ. Ent.*, 26 (1933), No. 2, pp. 438-445, pls. 2, fig. 1).—The authors describe the so-called "apple plug" method, devised for the purpose of minimizing certain difficulties experienced in insecticide tests of the codling moth. In using the "apple plug" method, small plugs of apple, uniformly sprayed with the insecticide under test, are sealed in glass cylinders. One codling moth egg is confined with each plug and, upon hatching, the larva encounters the insecticide as it attempts to gnaw its way through the skin of the fruit.

The technique of codling moth field experiments, C. R. CUTRIGHT and H. F. DIETZ (*Jour. Econ. Ent.*, 26 (1933), No. 2, pp. 392-401, figs. 3).—This is a detailed discussion of the principles that should govern the planning of codling moth field experiments.

A summary of three years' experiments on the control of codling moth in southwestern Michigan, F. SHERMAN III (*Jour. Econ. Ent.*, 26 (1933), No. 2, pp. 383-392).—Tests at the Michigan Experiment Station extending over a period of three years have shown that lead arsenate sprays may be expected to control the codling moth in heavily infested Michigan orchards.

"Summer oil emulsions and the summer oil-nicotine sulfate combinations have also resulted in good control under severe infestations. Following the use of lead arsenate sprays it was necessary to wash the fruit. This, it is shown, usually can be escaped if summer oils or the summer oil-nicotine sulfate combination is used for the summer brood sprays. It is shown that moth traps furnish valuable information which may be utilized in the spraying program. The importance of reducing codling moth population by supplementary control measures in severely infested orchards is emphasized."

The codling moth in southern Kansas and recommendations for its control, P. M. GILMER and R. L. PARKER (*Kansas Sta. Bul.* 263 (1932), pp. 29, figs. 6).—After a brief discussion of the importance of the codling moth and a description of its several stages, its life history in southern Kansas is briefly considered, followed by an extended account of methods of controlling the pest in that area with reference to supplementary measures and orchard income as affected by spraying practice.

It is pointed out that because of the heavy infestation by the codling moth in the Arkansas River Valley of southern Kansas a considerably different spray schedule and supplementary control program are required than elsewhere in the country. In that section the codling moth ordinarily has three generations. The studies have shown that "the first adults may be expected any time after April 15, the first eggs between May 5 and 15, and first-brood larvae from May 12 until late in June or early in July. First-brood adults may be expected any time after June 10, with the peak of emergence about July 1 to 10. The peak of second-brood adults may be looked for from August 10 to 20, and the peak of third-brood eggs about September 1. Practically all the larvae of the third brood hibernate, a very small number occasionally transforming to produce a small fourth brood of larvae all of which hibernate. The most effective spray program against the codling moth has been found to be the use of acid lead arsenate at the rate of 2 lb. to 50 gal. of water,

applied at the average rate of from 18 to 30 gal. per tree per spray, according to tree size, in 7 sprays. These sprays should consist of a calyx or petal-fall spray; 4 sprays applied to control the first brood, approximately at 2-week intervals after the calyx, the first coinciding in time with the first blotch spray; 2 sprays applied during July and August to control second-brood larvae; and, in especially bad years where control of early broods has been unsatisfactory, a late spray about August 15 to 20 to control the third-brood larvae. Supplementary measures, such as the use of chemical bands, proper pruning, cultivation, and packing-house and lug-box sanitation, are valuable aids in reducing the numbers of larvae that succeed in transforming into adults.

"Actual comparison in 1929 showed the cost of the recommended spray procedure to be approximately \$2.50 per tree per season, as against approximately 75 c. per tree per season under the present commercial practice. The income under average conditions of set and market, with trees mature and in good bearing, will be approximately \$7.28 per tree by the recommended method and \$4 per tree by the usual method. Increased income by the recommended method above spray costs amounts to approximately \$1.50 per tree, representing its financial advantage in average years over the usual method in use. A spray calendar for apples in the Arkansas River Valley of Kansas is included."

The net gain during the last decade in codling moth control information as indicated by experience under conditions especially favorable to the insect, G. M. LIST (*Jour. Econ. Ent.*, 26 (1933), No. 2, pp. 373-377).—Contributing from the Colorado Experiment Station, the author points out that extreme codling moth conditions determine the true value of control suggestions in a short period of time. "The proper use of arsenate of lead remains our most effective single control. Oil sprays in themselves are not a satisfactory control, but in certain combinations are of value. They complicate the spray residue problem and under many conditions are injurious to the fruit. Bait traps as a means of timing the application of sprays and the chemically treated bands are two of the most important recent developments. The use of the egg parasite, *Trichogramma minutum* Riley, has not shown a definite control under Colorado conditions. Unless more effective controls can be developed, some fruit growing areas must be classed as marginal."

Experimental results in codling moth control with late summer oil applications, C. R. CUTRIGHT and J. S. HOUSER (*Jour. Econ. Ent.*, 26 (1933), No. 2, pp. 380-383).—In work extending over a period of 4 years the authors have found that refined oil sprays applied in midsummer are not as effective as arsenate of lead applied at the same time for codling moth control. The ratio of entrances to stings is always higher on oil-sprayed plats than on those sprayed with arsenate of lead. The oils used in midsummer, however, have been quite effective in lowering the arsenical residues.

Chemically treated bands, M. D. FARRAR and W. P. FLINT (*Jour. Econ. Ent.*, 26 (1933), No. 2, pp. 364-368, fig. 1).—The authors find in studying over a 5-year period in Illinois that the cold dipped, corrugated paper band (powdered beta naphthol 1 lb., 200-300 seconds viscosity oil 1.5 pt., gasoline 1 pt.) has been as effective in stopping codling moth emergence as the hot dipped band. The cold band has advantages as to uniformity of deposit, fire hazard, and ease of preparation. Now cold dipped formulas of high efficiency are given.

The *Pyrausta* corn borer in the Netherland East Indies (*P. nubilalis* Hbn.) [trans. title], C. J. H. FRANSSEN (*Landbouw [Buitenzorg]*, 8 (1932), No. 4, pp. 266-284, figs. 3; *Eng. abs.*, pp. 283, 284).—The author reports that comparative morphological investigations of moths from Java, Celebes, the Philippine Islands, and the United States have shown the species observed in the

islands of Java, Sumatra, and Borneo to be identical with the common European corn borer. Observations of its life history made at Sengkang in the Celebes and Buitenzorg in Java are recorded. It is said to be of little importance in the Netherlands East Indies, only two serious outbreaks in Java having come to the author's attention.

Experimental destruction of the eggs and larvae of the wax moth (*Galleria mellonella* L.) by use of insecticides [trans. title], A. BORCHERT and K. VÖHRINGER (*Berlin. Tierärztl. Wchnschr.*, 48 (1932), No. 50, pp. 805-807).—Tests made of sulfoliquid, areginal, hexachlorethane, and Cyanogas indicate that all four are effective in destroying the eggs and larvae of the wax moth.

The description and biology of *Nepticula braunella* new species (Lepidoptera—Nepticulidae), a species of leaf miner on *Prunus ilicifolia* Walp. and the variety *integrifolia* Sarg., W. W. JONES (*Calif. Univ. Pubs. Ent.*, 6 (1933), No. 4, pp. 49-78, figs. 10).—This account deals with the Pacific coast species *N. braunella* n. sp., which attacks *P. ilicifolia* and *P. ilicifolia integrifolia* and is typical of half a dozen California species previously studied comparatively. There are said to be two main broods a year, although stragglers in the larval stage are encountered all the year round depending on the weather. A list is given of 85 references to the literature.

Insect enemies of the corn earworm (*Heliothis obsoleta* Fabr.), T. F. WINBURN and R. H. PAINTER (*Jour. Kans. Ent. Soc.*, 5 (1932), No. 1, pp. 1-28).—In a study of the literature at the Kansas Experiment Station, a list of 47 references to which is included, 82 species of insects were found recorded as enemies of the corn ear worm. Those most important in the Kansas region are the egg parasites *Trichogramma minutum* Riley and *Telenomus heliothides* (Ashm.), the larval parasite *Microplitis croceipes* (Cress.), and the predaceous bug *Orius insidiosus* (Say). The parasitism of the ear worm on corn is very small, showing that a parasite is needed which has a long ovipositor or habits which will enable it to reach the corn ear worm larvae in spite of the protecting shucks. At the station two new insect enemies of the corn ear worm were found, namely, *Chrysopa plorabunda* Fitch and *Microplitis* sp. near *melanæ* Vier.

Clothes moths and carpet beetles, T. J. HEADLEE (*New Jersey Stat. Circ.* 264 (1933), pp. 4).—A brief practical account.

The relative toxicity of nicotine, anabasine, methyl anabasine, and lupinine for culicine mosquito larvae, F. L. CAMPBELL, W. N. SULLIVAN, and C. R. SMITH (*Jour. Econ. Ent.*, 26 (1933), No. 2, pp. 500-509, fig. 1).—The authors have found that, based on the concentration required to kill 50 percent of a population of culicine mosquito larvae in 8 hours at 29.3° C. (84.7° F.), the relative toxicity of four alkaloids is as follows: Nicotine 100, anabasine 38, methyl anabasine 21, and lupinine 6 (?). According to unpublished observations of others, nicotine and anabasine may be equally effective against aphids. Nicotine and anabasine are much less toxic than rotenone against mosquito larvae and house flies. Methods for preparing the alkaloids and for obtaining, rearing, counting, and transferring mosquito larvae are described.

Automatic distribution of paris green for malaria control, P. F. RUSSELL (*Jour. Parasitol.*, 19 (1933), No. 3, pp. 215-224, figs. 6).—The author reports upon two experiments conducted with an automatic distributing machine from which a mixture of sand and paris green falls on a stream continuously for some hours each week. A large proportion of the anopheline mosquito larvae breeding in streams were killed by the paris green so distributed, even at a distance of 10 m downstream.

Bloodsucking and non-bloodsucking flies in relation to human welfare (*Ann. Ent. Soc. Amer.*, 25 (1932), No. 3, pp. 603-630).—The papers presented at a symposium held at the annual meeting of the Entomological Society of America at New Orleans, La., here presented include the following: Bloodsucking Flies (Exclusive of *Culicidae*) in Relation to Human Welfare, by H. H. Schwardt (pp. 603-613); Mosquitoes in Relation to Human Welfare, by E. H. Hinman (pp. 613-623); and Non-bloodsucking Flies as Vectors of Pathogenic Micro-organisms, by W. B. Herms (pp. 623-628). A discussion of the symposium papers, by E. C. Faust, follows (pp. 629, 630).

New method in sand fly studies (Diptera: Chironomidae), D. G. HALL, J. B. HULL, and W. E. DOVE (*Ent. News*, 44 (1933), No. 2, pp. 29-32, pl. 1).—This contribution describes methods for obtaining adult sand flies, the preservation of the natural shape and color of such adults, and the preparation of immature stages for microscope slides. An automobile headlight trap for collecting insects is described, together with a preservative fluid which gives natural shape and color in specimens of sand flies.

The salt marsh sand fly problem (*Culicoides*), W. E. DOVE, D. G. HALL, and J. B. HULL (*Ann. Ent. Soc. Amer.*, 25 (1932), No. 3, pp. 505-522, pls. 3, figs. 2).—This is a preliminary account of bloodsucking midges occurring along the Atlantic and Gulf coast littorals. Methods of combating these pests are outlined.

Influence of light on the gorging of *Culex pipiens* L., P. TATE and M. VINCENT (*Nature [London]*, 130 (1932), No. 3279, pp. 366, 367).—The results of studies of the effect of light upon engorging mosquitoes are said to have shown definitely that under experimental conditions in England the common house mosquito *C. pipiens* will engorge readily when placed in the dark after prolonged exposure to light, but if kept continuously in the dark will only rarely engorge.

Susceptibility of English *Culex pipiens* L. to infection with bird malaria, P. TATE and M. VINCENT (*Nature [London]*, 130 (1932), No. 3286, p. 630).—In experimental transmission of bird malaria by *C. pipiens* in England, the authors utilized the method of engorgement described in the contribution above noted. In the course of the experiments 393 mosquitoes engorged on birds heavily infected with the malaria parasite, *Plasmodium relictum* Grassi and Feletti, of which 131 were dissected and 72 (55 percent) found infected. Many mosquitoes showed more than 20 cysts on the stomach, and the salivary glands were heavily infected with this protozoan. Infected mosquitoes readily transmitted the parasite to healthy canaries. This is considered to have been the first published record of the transmission of bird malaria by *C. pipiens* in England.

Dragon-flies predacious on *Tabanus* spp. (Dipt.: Tabanidae), E. H. HINMAN (*Ent. News*, 44 (1933), No. 2, pp. 49, 50).—The so-called green jacket dragon fly, *Mesothemis simplicicollis* Say, was observed by the author in southern Louisiana to feed extensively on the horseflies *T. conterminus* Walk. and *T. nigrovittatus* Macq.

The life histories of two horse-flies, H. H. SCHWARDT (*Ann. Ent. Soc. Amer.*, 25 (1932), No. 3, pp. 631-637).—This is a report of studies of the life histories of the black horsefly and *Tabanus trimaculatus* P. de B., conducted in the period 1929-1931 at Fayetteville, Ark., in continuation of earlier work (E.S.R., 63, p. 753; 66, p. 557).

The large narcissus fly, *Merodon equestris* Fab. (Syrphidae), W. E. H. HOBSON (*Bul. Ent. Res.*, 23 (1932), No. 4, pp. 429-448, pl. 1, fig. 1).—This

is a review of the history, morphology of the immature stages, and biology of, and control measures for, the narcissus bulb fly.

Preliminary report on a study of the biology of *Lixophaga diatraea* Tss., L. C. SCARAMUZZA (*Asoc. Téo. Azucareros Cuba, Proc. Ann. Conf., 4 (1930), pp. 59-63*).—This is an account of the tachinid *L. diatraea*, the most important and effective larval parasite of the sugarcane borer in Cuba, Puerto Rico, and some of the other islands of the West Indies, parasitism in Cuba reaching as high as 40 percent during spring and summer. "The flies are larviparous, and borer larvae can be inoculated by dissecting gravid females and placing maggots on the host. There are three larval stages, of which part of the first and second are attached to the trachea of the host while the third is always free within the host body. Six to seven days are required for the prelarviposition period, 5.5 to 13 days in the larval stages, and 9 to 11 days in the pupal stage, making 20.5 to 30 days for the complete life cycle."

The relative toxicity of trisodium arsenite and arsenious acid to the house fly, *Musca domestica* L., A. M. PEARSON and C. H. RICHARDSON (*Jour. Econ. Ent., 26 (1933), No. 2, pp. 486-493*).—In studies in Iowa, solutions of arsenious acid and trisodium arsenite of various pH values were fed quantitatively to newly emerged adult house flies. "The solutions contained 15 g of sucrose per 100 cc. Under these conditions, the toxicity of arsenious acid (pH 6.58 to 6.96) was indistinct from that of trisodium arsenite (pH 11.3 to 11.4), possibly the result of buffer action within the digestive tract. The minimum lethal dose for the two forms of trivalent arsenic was 0.14 mg arsenic per gram of body weight. This is comparatively a large minimum lethal dose for an insect. Arsenious acid solutions were not repellent at any arsenic or hydrogen-ion concentration used; trisodium arsenite solutions of equivalent As concentration were not repellent at pH 11.3 and 11.4, but were distinctly repellent at higher pH values. In practice, no more alkali should be added to a house fly bait than is necessary to hold the trivalent arsenic in solution."

The biology and economic status of New Zealand Muscidae and Calliphoridae.—Part I, Historical review, D. MILLER (*Bul. Ent. Res., 23 (1932), No. 4, pp. 469-476*).—This first part consists of a historical review presented in connection with a list of 42 references to the literature.

Dispersal of the apple maggot—1932 studies, C. R. PHIPPS and C. O. DIRKS (*Jour. Econ. Ent., 26 (1933), No. 2, pp. 344-348, pl. 1, fig. 1*).—This contribution from the Maine Experiment Station records the recovery of 130 marked apple maggot flies out of a total of 3,152 which were released in one site. These marked flies were recovered at distances varying from 65 to 233 yards from the point of release. Although released in unsprayed trees bearing many apples, the marked flies soon left them, as they did unsprayed non-bearing trees in similar experiments in 1931. Marked flies released in young sprayed apple trees were not recovered.

Notes on the biology of the apple maggot, C. R. PHIPPS and C. O. DIRKS (*Jour. Econ. Ent., 26 (1933), No. 2, pp. 349-358, pls. 2, figs. 4*).—A further contribution from the Maine Experiment Station reports upon the life history of the apple maggot in that State. The observations made indicate that the time of fly emergence is governed by a number of factors, such as variety of fruit in which the larva develops, nature of the soil, location, and amount of rainfall during the emergence period.

"In order to obtain large quantities of the larvae for various purposes a special trap was developed. A small fall or second brood of flies has been produced in our cages each year in one section of the State but not in the others where the soil is heavier. Only larvae which develop in early or summer va-

rieties transform to flies the same season. Practically all the second generation flies appear during the first 2 weeks in October, hence they are not of economic importance. Two-year cycle flies are likewise recorded. Counts covering the daily sex records of nearly 23,000 flies in 1932 indicate that the period during which the males and females emerge in nearly equal numbers coincides with the peak of emergence."

The host relations of our cherry fruit flies, H. GLASGOW (*Jour. Econ. Ent.*, 26 (1933), No. 2, pp. 431-437, pls. 2).—In this contribution from the New York State Experiment Station, the author reports that *Prunus serotina* appears to be the principal native host for the cherry fruit fly, while the black cherry fruit fly is confined chiefly to *P. pennsylvanica*. These two fruit flies are not well adapted to the native chokecherry, *P. virginiana*, and this fruit appears to be of little importance as a host for either species.

Insects in relation to fruit injuries, A. A. GRANOVSKY (*Minn. Hort.*, 59 (1931), No. 3, pp. 60, 61, figs. 6; *abs. in Minnesota Sta. Rpt. 1932*, p. 34).—In this brief general account mention is made of the carrying by the apple maggot of a bacterial organism that causes and hastens the decay of apples in storage.

Records of some insects predacious on *Epilachna corrupta* Muls. in Mexico, C. C. PLUMMER and B. J. LANDIS (*Ann. Ent. Soc. Amer.*, 25 (1932), No. 4, pp. 695-708, fig. 1).—A report is given of observations made during the summer of 1930 of enemies of the Mexican bean beetle on bean foliage and wild solanaceous plants in Mexico.

Preliminary tests with liquid bait in Japanese beetle traps, F. W. METZGER (*Jour. Econ. Ent.*, 26 (1933), No. 2, pp. 411-414, pl. 1).—This is an account of an attempt made to devise a method of maintaining the attractiveness of the geraniol and eugenol baits over a considerable period of time when exposed in the field. The results indicated that when wicks of a certain size were used in traps of two types, more beetles were captured than in check traps containing the bran-molasses mixture with the attractants added.

Economic status of the Japanese beetle in 1932, L. H. WORTHLEY and C. W. STOCKWELL (*Jour. Econ. Ent.*, 26 (1933), No. 2, pp. 405-410).—This is a summary of the economic status of the Japanese beetle at the end of the year 1932, in which year this beetle probably caused greater destruction of fruit and produce crops than at any time since its discovery in the United States in 1916.

The spread of Dutch elm disease by elm cambium beetles and the control of this insect in practice [trans. title], J. J. FRANSEN (*Tijdschr. Plantenziekten*, 37 (1931), No. 3, pp. 169-187, pls. 3; *abs. in Rev. Appl. Ent.*, 20 (1932), Ser. A, No. 1, p. 4).—An account of the spread of *Graphium ulmi* by *Scolytus scolytus* F., together with natural and artificial measures of control. The braconid *Ooeloides scolyticida* Wesm. is an important enemy, parasitism by it sometimes reaching 100 percent. An account of the discovery of this disease in the United States in 1930 by May and Liming in Ohio has been noted (*E.S.R.*, 65, p. 448).

White-pine weevil attack on Scotch pine, H. J. MACALONEY and J. W. JOHNSTON (*Jour. Forestry*, 31 (1933), No. 1, pp. 26-28).—This brief account includes tables giving (1) the relative amount of attack and the number of leaders actually killed compared with the total number of trees examined and (2) the severity of attack and the number of dead leaders in four plats at Harvard Forest, Petersham, Mass.

Relation of temperature to the development of the plum curculio in apples, W. D. WHITCOMB (*Jour. Econ. Ent.*, 26 (1933), No. 2, pp. 415-419).—Contributing from the Massachusetts Experiment Station, the author points

out that the rate of development of the immature stages of the plum curculio increases with each increase in temperature above 55° F.

"The number of punctures by adults in unsprayed apples also increases with the temperature, but less rapidly than the number of eggs deposited. When confined with apples sprayed with lead arsenate, the number of days which the beetles live and the number of punctures which they make before death decreases with each increase in temperature and each increase in the concentration of lead arsenate. By applying sprays or dusts just before the first period of high temperatures following the petal fall stage, fruit growers have decreased injury by this insect 11 to 20 percent, compared to less timely applications."

Further studies on the control of the apple curculio in the Champlain Valley. O. H. HAMMER (*Jour. Econ. Ent.*, 26 (1933), No. 2, pp. 420-424, fig. 1).—This is a report of additional life history studies (E.S.R., 67, p. 719) of the apple curculio by the New York State Experiment Station. In the experimental plots partial control was again secured by properly timed heavy applications of lead arsenate sprays.

House ants. T. J. HEADLEE (*New Jersey Stat. Circ.* 265 (1933), pp. 3).—A brief practical account.

Further information on chlorine sterilization of beekeeping equipment. H. G. AHRENS and M. C. TANQUARY (*Amer. Bee Jour.*, 72 (1932), No. 1, pp. 12-14, 33, 34, figs. 6; abs. in *Minnesota Sta. Rpt.* 1932, pp. 35, 36).—A method for sterilizing beekeeping equipment by chlorine as developed at the station is described.

The biology of *Encyrtus infidus* Rossi, a parasite of *Lecanium kunoensis* Kuw. (Hymen.). C. P. CLAUSEN (*Ann. Ent. Soc. Amer.*, 25 (1932), No. 4, pp. 670-687, pl. 1).—The author has found *E. infidus* to be parasitic in *L. kunoensis* in central Chosen (Korea), where it produces two generations and a partial third each year upon the one host generation. "The gross parasitization effected in the field approximates 100 percent, yet control is not effected, owing to the fact that the host females are able to deposit approximately half of their quota of eggs before death. . . . In the spring generation pupation takes place within the unbroken larval skin in the living host. The death of the host results from mechanical injury at the time of emergence of the first parasite, rather than as a direct result of the feeding of the parasite larvae upon the body contents."

Notes on breeding *Macrocentrus ancylivorus* from reared hosts. P. GABMAN (*Jour. Econ. Ent.*, 26 (1933), No. 2, pp. 330-334).—This is a discussion of the methods found most efficient in the rearing of *M. ancylivorus*, an important parasite of the oriental fruit moth.

A new parasite of *Laspeyresia molesta* Busck. T. UCHIDA (*Jour. Wash. Acad. Sci.*, 23 (1933), No. 3, pp. 147, 148, fig. 1).—Under the name *Dioctes molestae* the author describes a new ichneumonid parasite reared from the oriental fruit moth in Japan.

Methods of breeding *Trichogramma* in Connecticut. J. C. SCHREAD (*Jour. Econ. Ent.*, 26 (1933), No. 2, pp. 402-404, pl. 1).—A discussion of the methods employed at the Connecticut State Experiment Station in the large-scale rearing of the egg parasite *T. minutum*.

Contribution to the study of the parasites and hyperparasites of *Hypomeceta malinellus* Zell. [trans. title], P. VOUKASSOVITCH (*Rev. Zool. Agr. et Appl.*, 31 (1932), Nos. 7, pp. 108-120, pl. 1, figs. 6; 8, pp. 124-136, figs. 3; 9, pp. 137-145, figs. 4; 10, pp. 153-160, pl. 1, fig. 1; 11, pp. 174-183, figs. 4).—The parasites of the ermine moth noted include *Herpestomus brunneicornis* Grav., *Angitia armillata* Grav., *Pimpla examinatrix* F., *P. maculator* F., *Agrypon*

anzium Wesm., *Brachymeria* (*Chalcis*) *minuta* L., *Ageniaspis fuscicollis* Dalm., *Tetrastichus crassinervis* Thoms., *Discochaeta cognata* Schin., and *Agria mamillata* Pond. Seven species of hyperparasites are noted.

Hymenopterous parasites from the eggs of aquatic and semi-aquatic insects, C. H. HOFFMANN (*Jour. Kans. Ent. Soc.*, 5 (1932), No. 2, pp. 33-37).—A brief summary of the literature presented in connection with 34 references.

Miscellaneous descriptions and notes on parasitic Hymenoptera, A. B. GAHAN (*Ann. Ent. Soc. Amer.*, 25 (1932), No. 4, pp. 736-757).—Descriptions of 11 species and 1 variety of hymenopterous parasites, representing 8 families, as new are accompanied by synonymical and distributional notes.

A parasitic hymenopteron as a vector of an insect disease, N. M. PAYNE (*Ent. News*, 44 (1933), No. 1, p. 22).—Mention is made of the transmission of a sporozoan disease of the larvae of the Mediterranean flour moth due to *Thelohania ephesiae* Mattes by the braconid *Microbracon hebetor* Say.

Experiments on the control of mites infesting raspberries, R. HUTSON (*Jour. Econ. Ent.*, 26 (1933), No. 2, pp. 425-430).—Contributing from the Michigan Experiment Station, the author considers the nature of the damage, the distribution, and loss sustained from mites, particularly *Tetranychus mcDanieli* McG., on raspberries in that State, together with control measures.

A series of three sprays of summer oil at 1 percent strength reduced the mite population to an extremely low figure in May 1931, while an identical series of sprays applied just after the leaves came out in 1932 protected raspberries from damage by mites. Raspberry foliage is apparently entirely tolerant to sprays of 1 percent summer oils.

The Rocky Mountain wood tick, R. A. COOLEY (*Montana Sta. Bul.* 268 (1932), pp. 58, pl. 1, figs. 14).—This account of the Rocky Mountain spotted fever tick, known both as *Dermacentor venustus* Banks and *D. andersoni* Stiles, following an introduction, deals with other ticks liable to be mistaken for it, including the winter tick, American dog tick, rabbit tick, and several species of less importance in Montana; the responsibility of the spotted fever tick in human diseases and in diseases of domestic animals; life history; conditions favoring its abundance; the tick season; habits of unfed adult ticks in nature; and geographical distribution. Its adaptations are then taken up and followed by descriptions of dressings used to avoid ticks, tick bites, removal of the attached tick, fear of ticks, experiences in the control of the tick, other methods of control, general considerations in control, and tick parasites. A list of 37 references to the literature is included.

Results of an investigation concerning the timbers of the Netherland East Indies which are resistant against Teredo [trans. title], J. W. GONGGRIJP (GONGGYP) (*Dept. Landb., Nijv. en Handel Nederland Indië, Meded. Boschbouwproefsta.*, No. 25 (1932), pp. 1-99, pls. 12; *Eng. abs.*, pp. 85-87).—This account is said to be a continuation and extension of an investigation commenced in Surinam with a view to discovering new timbers resistant against *Teredo* and to test the correctness of the hypothesis that a certain content of silica particles renders timbers possessing a certain degree of firmness immune against attack. It includes a description of the anatomy of *Teredo* and a summary of the 12 subgenera into which the species of the genus are separated.

Further results of investigations about the resistance of Netherland East Indian timbers against the attack by Teredo and other marine borers [trans. title], A. T. J. BIANCHI (*Dept. Landb., Nijv. en Handel Nederland Indië, Meded. Boschbouwproefsta.*, No. 25 (1932), pp. 101-147; *Eng. abs.*, pp. 130-132).—This second contribution (see above) consists of a compilation of information obtained from various sources on the resistance of timbers of the Netherland East Indies to attack by marine borers.

Nuttallia minor n. sp., new blood parasite of horses [trans. title], D. N. ZASUKHIN (SASSUCHIN) (*Vest. Mikrobiol., Epidemiol. i Parazitol. (Rev. Microbiol., Épidémiol. et Parasitol.)*, 11 (1932), No. 3, pp. 181-185, pl. 1, fig. 1; *Eng. abs.*, p. 185).—A description is given of a new piroplasm (*N. minor*) found in blood films from 107 horses attacked by a disease the etiology of which has not been worked out. Mention is made of three ticks suspected of transmitting the parasite.

Some notes on the temperature regulation of normal susliks, *Citellus pygmaeus* Pallas [trans. title], I. U. RALL (G. RALL) (*Vest. Mikrobiol., Epidemiol. i Parazitol. (Rev. Microbiol., Épidémiol. et Parasitol.)*, 11 (1932), No. 3, pp. 197-207, figs. 3; *Eng. abs.*, pp. 206, 207).—The author concludes that the heat regulation of normal susliks, *C. pygmaeus*, is abated and their body temperature follows rather flexibly that of the surroundings.

ANIMAL PRODUCTION

[Livestock investigations in Florida] (*Florida Sta. Rpt. 1932*, pp. 49, 50, 51, 52, 53, 54, 55, 56, 57).—Results are reported dealing with the use of species of *Crotalaria* as forage crops and hay for rabbits, by G. E. Ritchey, and for cattle, by R. B. Becker; adaptability of various pasture grasses to the peat and muck soils of the Everglades, by A. Daane and R. W. Kidder. Other tests dealt with the wintering of steers on peanut hay alone and the comparative value of Bermuda, Bahia, Dallis, centipede, and carpet grasses for fattening beef cattle, by A. L. Shealy, and the use by Becker of an iron-copper-salt mixture for cattle and swine.

Comparison was made of dry lot feeding and grazing on Spanish pearnuts, corns, chufas, and sweetpotatoes, alone and in combination, and runner peanuts and runner peanuts and oats for fattening fall pigs, by Shealy.

Data are given on tests of the effect of various vermifuges on egg production, as well as the toxicity and palatability of *Crotalaria* seed on chickens and quail, by E. F. Thomas.

[Livestock investigations in Georgia] (*Georgia Sta. Rpt. 1932*, pp. 27, 28, 29, 30, 32, 33).—Data are reported from a comparison of tankage and tankage and cottonseed meal in equal parts with tankage and peanut meal in equal parts as protein supplements to shelled corn for swine; preliminary tests of the value of menhaden oil for swine; a test with fattening beef cattle in which alfalfa, cowpea, and peanut hays and cottonseed hulls were fed as a supplement to a concentrate ration; and of the results when green oats and corn were ensiled in a trench silo without chopping.

[Investigations with livestock] (*Kansas Sta. Biem. Rpt. 1931-32*, pp. 55-63, 74-81, 108, 109, 110, 121, 124).—Data obtained in studies with pigs are reported on the nutritive requirements of swine, by C. E. Aubel, J. S. Hughes, and H. F. Lienhardt; swine-feeding investigations, by Aubel and W. E. Connell; and alfalfa pasture for swine at the Garden City Substation.

The beef cattle studies have yielded information on the use of silage for fattening beef cattle, by A. D. Weber and Connell; the comparative nutritive value of dry matter in sorgo silage and fodder, by Weber; methods of utilizing native pasture in beef cattle feeding and a study of pasture values and pasture methods for livestock, by C. W. McCampbell; the influence of feed on the color, chemical composition, and cooking quality of the meat of grass-fat cattle, by McCampbell et al.; the antagonism of monovalent and polyvalent metals in the lipid fraction of beef, by H. H. King and J. L. Hall; and beef cattle feeding investigations at the Fort Hays Substation.

The poultry studies report data on poultry flock management; the comparative nutritive value of certain grain sorghums, corn, and wheat in poultry production; and the inheritance of slipped tendons, all by L. F. Payne; the effect of age and holding temperatures on the hatchability of turkey and chicken eggs; the temperature requirement of incubating turkey eggs; a comparison of the confinement and semiconfinement rotation systems of growing turkeys as measured by growth and mortality; the rate of growth and mortality of young turkeys as influenced by the ingestion of fibrous material; the effect of age of breeding turkeys on percentage production, distribution of production, egg size, and hatchability; and the value of tobacco powder in the prevention of enterohepatitis in turkeys, all by H. M. Scott; the effect of feeding a vitamin A low ration to growing poults; the effect of the lack of vitamin D on growing poults; the effect of feeding a vitamin A low ration to maturing Bronze turkey pullets and Single Comb White Leghorn hens; a quantitative study of the vitamin A requirement for growing poults; and a study of the rate of growth and embryonic development of Bronze turkey embryos, all by Scott and Hughes; the etiological factors involved in the malformation of bones in young chickens, by Payne, Hughes, Lienhardt, and L. D. Bushnell; and the relation of adequacy of diet to disease, by Hughes, C. A. Brandly, and Payne.

Results are also reported on comparison of Hampshire, Shropshire, Dorset, and Southdown sheep for wool, and of various rations for fattening range lambs, by R. F. Cox.

[Experiments with livestock in New Mexico] (*New Mexico Sta. Rpt. 1932*, pp. 28-33, 81-84, fig. 1).—Preliminary results of studies with cattle include data on mineral feeding of range cattle as it affects calf crop and rate of gain, digestibility and mineral balances when native New Mexico mixed range grasses are fed and digestibility and mineral balances when mineral supplements are added, and steer feeding experiment, 1931-32. The work with sheep included a study on the feeding of whole corn plant as ground fodder and as silage for fattening lambs. The poultry studies report data on poultry breeding and feeding.

Investigations into the intensive system of grassland management, IV—XI (*Jour. Agr. Sci. [England]*, 21 (1931), No. 3, pp. 414-424, fig. 1; 425-441, figs. 2; 452-457, 469-475; 22 (1932), No. 2, pp. 235-290, figs. 5).—This series of studies (E.S.R., 67, p. 297) has been continued.

IV. *The digestibility and feeding value of artificially dried grass*, S. J. Watson (pp. 414-424).—Digestion trials with sheep were conducted to obtain information as to the digestibility and feeding value of artificially dried grass. The grass used was obtained from an area that had been intensively treated and which had received a dressing of nitrogen four weeks prior to the date of cutting. The grass was dried in an experimental band drier. A portion of the grass was fed as it came from the drier, while another portion was ground into a meal. A feeding trial was also undertaken with dairy cows to determine the feeding value of such grass.

With sheep the digestibility of the two samples of grass was high, and with the exception of crude protein was equal to values quoted for short grass. In both cases the sheep gained in weight, and there was also a retention of nitrogen and mineral matter. The grass appeared to contain sufficient calcium, phosphorus, and potash for the plane of nutrition at which it was fed. The high digestibility of the crude protein and the narrow nutritive ratio of dried grass and grass meal proved that the material was superior to hay of excellent quality. This was true in spite of the fact that the grass was cut in August when the protein content was lower than might normally be expected.

The trial with dairy cows showed that artificially dried grass was readily eaten and produced the amount of milk for which the nutrients it supplied were theoretically capable.

V. *The digestibility and feeding value of grass silage made in a tower, and the digestibility and comparative yield of artificially dried grass obtained from the same source*, S. J. Watson (pp. 425-441).—Grass from a field of permanent grass which had reached a stage when it might have been cut for early hay and in which there was little clover was placed in a silo. Samples of grass in sacks were put in the silo at varying levels, and a drain was constructed at the bottom of the silo so that the loss by drainage could be determined. The digestibility of the silage was determined in trials with sheep, and its value under practical conditions was determined by feeding to dairy cows.

The loss by drainage was negligible, while at the same time fermentation losses were not high. The silage produced was a highly nutritious feeding stuff. The dairy cows ate the silage readily, and their milk production was not affected when the silage replaced all of the hay in the maintenance ration. The amounts of starch equivalent and digestible crude protein were somewhat higher in artificially dried grass than in grass silage, while the digestible true protein was considerably lower in the silage. However, it should be remembered that in general practice grass silage would be substituted for ordinary hay and not for artificially dried grass.

VI *The digestibility and feeding value of grass silage made in a stack*, S. J. Watson (pp. 452-457).—Grass silage was made in stacks from aftermath grass from an old grassland which had received basic slag and potash for the hay and nitrogen for both hay and aftermath. The silage was made in stacks 15 ft. in diameter. Digestibility trials with sheep were carried out on two samples of this silage.

The digestibility of the crude fiber of the silage was quite high, and in addition the fiber content was low. In digestibility of other constituents the two samples of silage compared favorably with other silages. However, there was evidence of a depressive effect on the digestibility of the crude protein as compared with meadow hay. It is concluded that making stack silage was a useful method of conserving surplus grass, particularly of the aftermath type, when good haying weather was lacking. No feeding trials were conducted, but the silage was fed to stock with satisfactory results.

VII. *The digestibility and feeding value of grass silage made in a pit*, S. J. Watson (pp. 469-475).—Grass which had reached the flowering stage, having grown beyond the optimum stage for hay making, was made into silage in a concrete pit. The grass used was of poor quality, and as a result the fiber content of the silage was high and the crude protein and ash low. The digestibility of the silage was determined in trials with sheep.

The digestibility of all the constituents compared favorably with meadow hay except that of protein, which showed a depression. The starch equivalent of this silage was higher than that of meadow hay when compared on a dry-matter basis. It was also equal in digestible protein content to poor-quality meadow hay. The silage was eaten readily by dairy cows on pasture within 4 weeks after being made.

VIII. *The comparative digestibility and feeding value of fresh and artificially dried grass*, S. J. Watson and W. S. Ferguson (pp. 235-246).—A series of two tests was undertaken to compare the digestibility of fresh grass and that of grass cut at the same time and from the same source but dried in a drier heated by air at an inlet temperature of either 200° or 800° C. With the exception of crude protein, which was slightly depressed, there was no difference in the digestibility of the various constituents at the 200° inlet

temperature. However, at the higher temperature there was a depression in the digestibility of all the nutrients, especially of the protein where the effect was very marked. These results indicated that while the use of the higher initial temperature increased the output of the drier it adversely affected the digestibility of the final product.

IX. *The digestibility of artificially dried hay*, S. J. Watson and W. S. Ferguson (pp. 247-250).—In this test a mixture of clover and ryegrass was cut when from 9 to 12 in. in length and was stacked while green around a conical-shaped tower of pipe through which water was circulated at an average temperature of from 100° to 110° F. for 45 hours. The finished hay was of excellent quality and high digestibility. It had a higher feeding value than good meadow hay or seeds hay and was made at a season when haying conditions were poor. No attempt was made to determine the economics of this practice.

X. *A further study of the mineral content of intensively treated pasture*, W. S. Ferguson (pp. 251-256).—The results published in this paper are in amplification of and include a more complete mineral analysis of samples used in an earlier study (E.S.R., 67, p. 297). In addition to the more common mineral elements, determinations were made for magnesium, manganese, iron, sulfur, and chlorine.

It was shown that the mineral content of intensive pastures was equal to that of the best type of pasture produced by other systems of management and superior to the average good cultivated pasture. Seasonal variations in soluble ash, potash, soda, and phosphoric acid depended principally upon climatic conditions. Drought in one case lowered the percentages of soluble ash, potash, and phosphoric acid. Correlations were found to exist between the nitrogen and phosphoric acid content and between the soluble ash and potash content, but there was no evidence of correlation between other constituents.

XI. *The effect of nitrogen on the yield, composition, and digestibility of grassland herbage*, S. J. Watson, J. Procter, and W. S. Ferguson (pp. 257-290).—Over a 2-year period tests were carried out to determine the effects of nitrogenous fertilizers, used in combination with rotational grazing on grass adequately supplied with potash, phosphates, and calcium. The effects were to a large extent governed by climatic conditions, and in the absence of sufficient moisture the increase in amount of herbage was reduced.

The average effects of nitrogen were to produce grass at an earlier date than normal and to increase the total yield of dry matter and crude protein per acre. Nitrogen caused a more uniform growth throughout the growing season and accelerated recovery after the midseason depression of growth. Where nitrogen was used autumnal growth was maintained at a higher level than on nontreated grass. The protein content of nitrogen-treated grass was increased, particularly at the most critical periods when the percentage in the nonnitrogen-treated grass fell to a very low level. The herbage on nitrogen-treated pastures had a high digestibility throughout the season.

The vitamin A content of alfalfa as affected by exposure to sunshine in the curing process, M. C. SMITH and I. A. BRIGGS (*Jour. Agr. Res. [U.S.]*, 46 (1933), No. 3, pp. 229-234).—Using the method of Sherman and Munsell (E.S.R., 54, p. 89), the Arizona Experiment Station measured the comparative destructive effect of curing periods of different length on the vitamin A content of alfalfa produced under Arizona conditions. The Hairy Peruvian variety of the third cutting from a planting in its second crop-year was cut when about 22 in. high. The cutting was done at 11.15 a.m., and one sample was taken immediately to a darkened curing house. The rest of the hay was spread in a swath so that the individual plants were separated, and samples were removed after being exposed for 2.8, 4.8, 6.8, 20.8 and 24.8 hours.

The vitamin A content of samples spread out in a field for 2.8 hours was from 20 to 33 percent less than that of the sample cured in the dark. No increased loss was found when the period of exposure was increased to 6.8 hours the same day, and there was no observed loss of green color in the leaves. Hay allowed to lie in the field until 8 a.m. the morning after cutting showed a loss of 75 percent in the vitamin A content, which was increased to 84 percent by a further 4-hour exposure when compared to the sample cured in the dark. The leaves of hay exposed for long periods retained a large part of their green color, but the stems showed evidence of marked bleaching. Alfalfa severely bleached by 1-week exposure to sun and rain in the swath had only 4 percent of the vitamin A present in the sample cured in the dark.

The antirachitic value of alfalfa as affected by exposure to sunshine in the curing process, M. C. SMITH and I. A. BRIGGS (*Jour. Agr. Res. [U.S.]*, 46 (1933), No. 3, pp. 235-240).—Three samples of hay, prepared as described in the preceding paper, were compared for their antirachitic properties. One sample was cured in the dark, the second sample was allowed to lie in the field from 11.15 a.m. one day to 12 m. the next day, during which time it received 15 hours 15 minutes exposure to sunlight of varying intensity, while the third sample lay in the swath for one week and received 57.3 hours of sunshine and during that time there was a precipitation of 0.37 in. of rain. The antirachitic potency was determined by the "line test" on rats.

Prolonged feeding of alfalfa cured in the dark did not alleviate induced rickets in the experimental animals, the second sample of hay possessed mild calcifying powers, while the third sample was highly antirachitic. The practicability of increasing the vitamin D content of alfalfa by prolonged exposure to sunlight is discussed, but the practice is not recommended because of the destruction of vitamin A and the weather damage to the hay.

The digestibility and feeding value of dreg meal, S. J. WATSON, (*Jour. Agr. Sci. [England]*, 21 (1931), No. 3, pp. 410-413).—Digestion trials were conducted with two lots of two sheep each to determine a true measure of the feeding value of dreg meal, a dried by-product of the production of alcohol. One lot received a ration of artificially dried hay and the other lot a ration of the same hay plus dreg meal.

This meal was found to be similar in feeding value to linseed cake. The meal proved to be a valuable feedstuff of high digestibility and feeding value and was suitable for feeding cattle and hogs as well as sheep. Because of its high oil content care should be taken in feeding the meal.

Mineral feeds, J. R. HAAG (*Oregon Sta. Bul. 309* (1933), pp. 12).—The mineral salts and elements essential to normal growth and reproduction are pointed out, their importance described, and their occurrence in feeds explained. The calcium and phosphorus contents of some feedstuffs and of calcium and phosphorus supplements are given in tabular form. When and how to use mineral supplements in animal feeding is explained. A section is devoted to proprietary mineral mixtures, pointing out that they should be judged by the value of their useful ingredients.

The relation of body shape of feeder steers to rate of gain, to dressing per cent, and to value of dressed carcass, J. L. LUSH (*Texas Sta. Bul. 471* (1932), pp. 30, figs. 5).—This study is based on measurements, made in a study previously noted (*E.S.R.*, 60, p. 254), with an extension of the data to include 25 lots of 241 steers which were fed at the Spur Substation from 1922 to 1929. Simple and multiple correlations and score cards, made up from the standard regression coefficients to show the importance of the relation of groups of variables to rate of gain, dressing percentage, and value of the dressed carcass, are presented.

The data show a tendency for initial weight to be positively associated with gains, dressing percentages, and final values of the steers, but when the measurements were taken into consideration initial weight became of less importance. The highest dressing percentages and the most valuable meat at the end of the feeding period were obtained from steers with large fleshy measurements but small body measurements as calculated from the regression coefficients. Much variability was noted in the relationship, so that predictions could not be very accurately made from the conformation of the feeder steer. The factors most closely associated with dressing percentage and meat value were large heart girth with a shallow chest, large loin and large flank girth, large initial weight, small paunch girth, narrow head at the eyes, and short height over hips. Gains were associated with length of body and height at withers, paunch girth, flank girth, and width at loin. The data indicate that no plan based on conformation of the feeder steers could ever estimate future performance without many mistakes. Much variability was shown in the relationship of the shape of steers to the gains made.

The glyceride structure of beef tallows, A. BANKS and T. P. HILDITCH (*Biochem. Jour.*, 25 (1931), No. 4, pp. 1168-1182, fig. 1).—An analysis was made of one sample of North American beef tallow and three samples of tallow from South America at the University of Liverpool to determine the content of fully saturated glycerides, the fatty acids which go to make up these glycerides, and also those of the whole fats.

In the whole fats the combined molecular percentage of stearic, oleic, and linoleic acids tended toward one of two definite figures in spite of wide variations in the amount of stearic and a corresponding variation of oleic with linoleic acid. The proportion of fully saturated glycerides present varied according to the relative amount of saturated and unsaturated acids in the whole fat. However, the composition of the acids was about 60 percent palmitic (with myristic) and 40 percent of stearic acid in all cases.

This regularity in structure is discussed in regard to the possible connection in the elaboration of storage fat in the animal.

Fattening range lambs in Idaho, E. F. RINEHART, C. W. HICKMAN, and R. F. JOHNSON (*Idaho Sta. Bul.* 194 (1932), pp. 48, figs. 10).—Concluding a series of studies (E.S.R., 66, p. 257) that have been conducted for a number of years at the Aberdeen and Caldwell Substations, it was found that quality of feeds, regularity of feeding, adequate watering facilities, and dry, comfortable lots, all added to the rapidity and economy of gains. When properly handled, lambs pastured on aftermath of hay fields, grain stubble, and beet tops gained from 10 to 15 lb. additional weight.

There was no material difference in the relative value of barley, corn, and wheat, but oats, while excellent to start lambs on grain, tended to produce growth. Cottonseed meal and linseed meal fed with barley and alfalfa increased the rate of gain, reduced the grain and hay requirements, and increased the market value of the lambs. Cull beans could replace about 20 percent of the barley satisfactorily, but larger quantities caused digestive disturbances. Cull peas, when replacing 20 percent of the barley, were a valuable supplement to barley and alfalfa, but when replacing only 10 percent did not make a favorable showing. Recleaned, heavy alfalfa seed screenings, when used to replace one third of the barley, were a valuable supplement.

Beet pulp whether stored wet, pressed, or fed fresh, was a valuable supplementary feed to alfalfa and barley, helped to keep the lambs on feed, and reduced the cost of gains. Cull potatoes, fed at the rate of 1 lb. per head daily, were found to be a useful feed, but cooking potatoes did not prove profitable.

Corn silage, when fed at the rate of 1 lb. per head daily, did not materially affect gains or feed requirements, but made a significant saving in alfalfa and increased the gains slightly when fed at the rate of 2 lb. per head daily. Corn silage was also valuable for maintaining thrift and keeping the lambs on feed. Chopping and grinding alfalfa had no significant effect on the rapidity or economy of gains but did effect a saving of hay. Alfalfa and clover chaff, being fibrous roughages, were not adapted to lamb-fattening rations.

Small lambs were as economical to feed as average-sized lambs, provided they were fed separately. The small lambs required a longer feeding period than the larger ones. In one year's test shearing lambs 35 days before marketing did not prove profitable. The shrinkage of lambs to market varied considerably, depending on home weighing conditions, finish of the lambs, proportion of grain and roughage, nature of the ship, comfort of the lambs in the car, condition of the feed yards en route, and the fill on the market.

Green soybeans, alfalfa, and permanent pasture as forages for fattening hogs, E. G. GODBAY, E. D. KYZER, and T. M. CLYBURN (*South Carolina Sta. Bul.* 289 (1933), pp. 16, figs. 2).—The results of two tests at Clemson College and two tests at the Coast Substation are reported, dealing with the comparative value of green soybean pasture with and without supplements of corn and fish meal and comparisons of the soybean pasture with alfalfa and permanent pasture.

There were 10 pigs in each lot, averaging at the start of the test from about 40 to 50 lb. The average results of the four tests showed that during the period of feeding to 200 lb. live weight the pigs in dry lot on corn and fish meal free choice made average daily gains of 1.4 lb., consuming 323 lb. of corn and 36 lb. of fish meal per 100 lb. of gain. When these feeds were fed free choice with green Biloxi soybean pasture the average daily gains were 1.59 lb., the pigs consuming 304 lb. of corn and 20 lb. of fish meal per 100 lb. of gain. Similar results were obtained with free-choice feeding of these feeds on green Otoftan soybeans. On alfalfa pasture and on permanent pasture the results obtained with free-choice corn and fish meal were as follows: 1.41 and 1.38 lb. average daily gains with 329 lb. of corn and 23 lb. of fish meal consumed per 100 lb. of gain in the former lot and 323 lb. of corn and 28 lb. of fish meal consumed in the latter lot. Gains of only 1.25 lb. per head daily were produced when corn alone was full-fed on green soybean pasture, and the consumption of corn was 349 lb. per 100 lb. of gain. Limiting the ration of corn to 2.5 percent on green soybeans reduced the gains to 0.96 lb. daily with a feed consumption of 282 lb. per 100 lb. of gain. When one part of fish meal was added to 15 parts of corn in the 2.5 percent limited ration on green soybeans, gains of 1.04 lb. daily were made, with a feed consumption of 258 lb. of corn and 18 lb. of fish meal per 100 lb. of gain. Limiting the corn and fish meal to 2.5 percent until the pigs reached 100 lb. live weight and finishing on corn and fish meal free choice with green soybean pasture throughout the test produced gains of 1.37 lb. at a feed consumption of 294 lb. of corn and 18 lb. of fish meal per 100 lb. of gain.

It is concluded from the test that the hogs fed corn and fish meal free choice with the soybean pasture made faster and cheaper gains than where the rations were limited, but the gains were less expensive where the corn and fish meal were limited during the first part of the fattening period. Both alfalfa and permanent pasture seemed to be of less value for fattening hogs than the soybeans. A large percentage of soft and oily carcasses were produced on rations limited to 2.5 percent of corn or 2.5 percent of corn and fish meal with the soybean pasture. A large percentage of the carcasses produced in the other lots were satisfactory.

The mineral requirements of pregnant sows, R. E. EVANS (*Jour. Min. Agr. [Gt. Brit.], 39 (1932), No. 6, pp. 544-548*).—Metabolism studies with pregnant sows were conducted at the Animal Nutrition Institute, University of Cambridge, to determine their mineral requirements. Two groups of sows received a balanced ration of barley meal, maize meal, bean meal, and blood meal, with 0.5 lb. of salt added to 100 lb. of mixed feed. Lot 1 received the basal ration only, while lot 2 received in addition about 1 oz. of ground limestone daily.

During the 115-day gestation period the sows in lot 1 retained an average of 38 g of lime, 646 g of phosphate, 110 g of potash, and 383 g of salt. The corresponding figures in lot 2 were 1,314, 720, 201, and 288 g, respectively. It was evident that the greatest deficiency in the basal diet was in the lime content. The animals in this group had to supply this necessary element by depletion of their own skeletons.

It is concluded that a suitable mineral mixture for pregnant sows not on pasture should consist of four parts of chalk to one part of common salt to be fed at the rate of 1 oz. per head daily. During the lactation period it is recommended that 2.5 oz. of this mineral mixture be fed daily.

Horse feeding, W. C. SKELLEY (*New Jersey Stat. Circ. 268 (1933), pp. 4*).—Practical directions are given for feeding horses under different conditions of work. The requirements of a satisfactory ration are discussed, and a table is given showing the average digestible nutrients in some of the common feeding stuffs.

Growth and chemical composition of ovum of functioning fowl's ovary (*Gallus domesticus*), A. L. ROMANOFF (*Biochem. Jour., 25 (1931), No. 4, pp. 994-996*).—The New York Cornell Experiment Station undertook a study of the storage of chemical elements in the ova during the early growth period as well as during maturation. The ova used were from White Leghorn hens of known history.

It was found that during the growth phases and particularly during the maturation phase the ovum increased rapidly in percentage of dry matter, reaching the highest point in a mature ovum. The calcium and fat content increased proportionately with the advance of maturation. The density and hydrogen-ion concentration, iodine number, and refractive index of the extracted fat changed but slightly during the maturation phase.

The effect of current interruption in electrical incubation, L. W. TAYLOR, C. A. GUNNS, and B. D. MOSES (*California Sta. Bul. 550 (1933), pp. 19, figs. 3*).—This study was planned to determine some of the specific effects of prolonged failure in the heat supply during electrical incubation on the hatchability of hen's eggs. The check lots of White Leghorn eggs received uninterrupted incubation at temperatures of from 101° to 102° F. for the first week, 102° to 103° for the second week, and 103° to 104° for the final week of incubation. The chilled lots were incubated under normal conditions except for several periods of 12 hours when the current was turned off. The room temperatures in the incubation room were maintained at 70°.

Under the conditions of this test current interruption produced an average decrease in the number of chicks hatched of 3.4 percent. The number of crippled and weak chicks produced by current interruption was approximately twice the number found with normal incubation conditions. While no critical day was found in which the developing embryo was particularly susceptible to chilling, current interruption during the second and third weeks of incubation brought about a greater mortality than that accompanying chilling during the first week. The increased loss due to chilling was expressed in an

increased proportion of deaths at the major peak points in the mortality curve. Since there was no specific type of embryonic mortality, it was apparent that the increased loss was of weak but normal-appearing embryos. The daughters of certain sires produced embryos that were susceptible to death from chilling, and the close relationship between some of these sires indicated that this susceptibility was a hereditary weakness.

Best age for the chick's first feed, A. C. SMITH (*Farmer*, 48 (1930), No. 18, p. 39; *abs. in Minnesota Sta. Rpt. 1932*, p. 33).—Studies were undertaken at the station to determine at what age chicks should first be fed. Comparable chicks were divided into lots and were fed 24, 36, 48, 60, and 72 hours after hatching.

The mortality rate at the end of 4 weeks was 18, 14, 10, 8, and 6 percent in the lots receiving feed after 72, 24, 36, 60, and 48 hours, respectively. At this time the average weight per chick was 143.2, 140.2, 133.1, 129.1, and 126 g in the lots first fed after 36, 48, 72, 24, and 60 hours. When all factors were considered it appeared that from 36 to 48 hours was the best time at which to give chicks their first feed, and the results also showed that there was a decided disadvantage in withholding feed for 72 hours.

Detection of washed, abraded, and oiled eggs, P. F. SHARP (*Indus. and Engin. Chem.*, 24 (1932), No. 8, pp. 941-946).—A method for detecting washed eggs is described in this article from the New York Cornell Experiment Station. The method is based on the observation that the material on the surface of the shell contains potassium and chloride which are removed by washing. Micro-precipitation tests of the shell extract from unwashed eggs gave tests for potassium and chloride, while the washed eggs did not give this reaction.

It was also found that oil treatment of eggs could be determined by dipping a portion of the shell in ethyl ether and observing the oily ring after the ether had evaporated. The sand-blast or scraping method of cleaning dirty eggs could be recognized by the absence of protein on the surface of the eggs as brought into prominence by staining.

The results of applying these tests to eggs of unknown history are presented.

Oiling does not make shell eggs more brittle, T. L. SWENSON and L. H. JAMES (*U.S. Egg and Poultry Mag.*, 38 (1932), No. 11, pp. 14-16, 58, figs. 2).—In studying the effect of oiling on the cracking strength of eggshells the U.S.D.A. Bureau of Chemistry and Soils used the following series of eggs: (1) Normal unoled eggs, (2) eggs oiled by dipping in an open oil bath, and (3) vacuum-carbon dioxide oil-dipped eggs. The determination of cracking strength was made by calculating the striking force of a mass of known weight falling as a free body through a given distance and measured in dynes.

The results of the study showed that there was a positive association between the thickness of the eggshell and the force in dynes necessary to crack it. The effect of oiling upon the breaking strength was so slight that it might be disregarded.

Application of ultra-violet radiation in the poultry industry, K. M. REM (*Agr. Engin.*, 14 (1933), No. 1, pp. 13, 14, figs. 4).—This abstract of a paper presented before the American Society of Agricultural Engineers reviews studies at different institutions on the effect of ultraviolet radiation of poultry, indicating its utility in increasing egg production and fertility and in hastening the growth of chicks.

Water-fowl and game-birds in captivity: Some notes on habits and management, A. F. MOODY (*London: H. F. & G. Witherby, 1932, pp. 240, pls. 6*).—The notes here presented are based upon personal observations of waterfowl and game birds.

DAIRY FARMING—DAIRYING

[Investigations with dairy cattle and dairy products] (*Kansas Sta. Bien. Rpt. 1931-32*, pp. 63-72, 121, 124, 125).—Data obtained in studies with dairy cattle are reported on milk as a sole diet for calves, the sugar and hemoglobin contents of the blood of dairy cattle, and the influence of the ration on the vitamin C content of cow's milk, all by H. W. Cave, W. H. Riddell, J. S. Hughes, C. H. Whitnah, and H. L. Lienhardt; a comparison of sorgo fodder and sorgo silage for milk and butterfat production, Atlas v. Kansas Orange sorgo silage for milk production, sorghum grains v. corn for developing dairy heifers, soybean v. alfalfa hay for milk and butterfat production, ground wheat v. ground corn for dairy cows, and silage weight determinations, all by J. B. Fitch and Cave; the influence of stage of maturity of sorgo silage on quality and composition, by Fitch, Cave, and W. L. Latshaw; dairy cattle pasturing investigations at the Fort Hays Substation; irrigated pastures for dairy cows at the Garden City Substation; and dairy herd improvement at the Colby Substation.

With dairy products information is reported on the use of fresh eggs in ice cream, investigations of chocolate ice cream, the use of vegetable stabilizers in ice cream, gelatin in sherbet mixes, the effect of pasteurization temperature on the bacteria flora of the ice cream mix, and testing ice cream mixes for butterfat, all by W. H. Martin and W. J. Caulfield; a bacteriological study of ice cream, by A. C. Fay; a study of the effectiveness of lye as compared with chlorine for sterilizing milking machine parts, by Caulfield and Riddell; and butter investigations, by Martin.

Soybeans for silage, R. B. BECKER, W. M. NEAL, C. R. DAWSON, and P. T. D. ARNOLD (*Florida Sta. Bul. 255 (1932)*, pp. 24, figs. 3).—Data are presented on the use of soybeans for silage and the comparative composition of soybean hay and soybean silage, supplemented with the results of a double reversal test in which soybean silage was compared with alfalfa hay for milk production. In 3 years' work it was found that more protein and mineral matter and less total digestible nutrients were produced per acre with soybeans than with corn used as the silage crop, and that silage was a more efficient conserver of the nutrients in the soybeans than hay. In three double reversal tests comparing alfalfa hay with soybean silage, the average results showed that when fed with corn silage and mixed grain a slightly larger amount of milk and butterfat were produced on the alfalfa hay rations. It was calculated that 2.93 lb. of soybean silage was equivalent to 1 lb. of alfalfa hay. No objectionable flavors or odors were noted in the milk as a result of the soybean silage feeding. Variations in the mineral content of the soybeans were associated with the rainfall. Additional calcium and phosphorus in the form of bone meal were consumed by the cows on the legume rations.

Soybean silage for dairy cows, R. B. BECKER (*Florida Sta. Rpt. 1932*, pp. 52, 53).—Silage from Biloxi soybeans was compared with alfalfa hay for milk production.

Investigations with roots as a feed for dairy cows [trans. title], H. W. ESKEDAL and V. STEENBERG (*Beret. Forsøgslab. K. Vet. og Landbohøjskoles [Denmark]*, 144 (1932), pp. [4]+112, figs. 21; *Eng. abs.*, pp. 102-105).—The animal husbandry division of the Royal Veterinary and Agricultural College's research laboratory conducted a series of feeding tests with dairy cows during the period 1927-31 to determine the feeding value of roots, marrow stem kale, and artificially dried and pressed feed cakes.

The results indicated that 1.1 kg of dry matter in roots could be considered equal to 1 F.E. (feed unit of about 1.66 therms) when approximately 40 kg of roots were fed per head daily. The amount of roots fed and the percentage of dry matter in the ration influenced the quantity of milk produced. An average of 1.8 kg of dry matter in marrow stem kale was equal to 1 F.E. Artificial drying and pressing did not appear to change the feeding value of the products tested, namely, oil cakes, dried offal products, dried sugarbeet pulp, and dried brewers' grains, but did improve their keeping quality and ease of handling.

Report of an experiment to determine the effect of a low calcium ration on reproduction in cattle, C. P. FITCH, W. L. BOYD, C. H. ECKLES, T. W. GULLICKSON, L. S. PALMER, and C. KENNEDY (*Cornell Vet.*, 22 (1932), No. 2, pp. 156-172; *abs. in Minnesota Sta. Rpt. 1932*, p. 31).—A group of seven dairy cows was maintained for a period of about three years on a ration containing approximately 0.18 percent of dry matter calcium, with other necessary food elements supplied, without any lessening of breeding efficiency. Two other groups of seven animals each were maintained on rations having calcium contents of 0.32 and 0.04 percent calcium, respectively, on a dry matter basis, and they also showed normal breeding efficiency. Essentially the same reproduction results were obtained with parallel groups of rats on low, medium, and high calcium rations.

The calcium content of the ration had no appreciable effect on the total calcium content of the blood plasma of the cows during the experiment, nor were there any changes in milk or fat production that could be attributed to the calcium level of the ration. The effects of the ration on the composition and properties of the milk were negligible. Balance trials indicated that the animals were able to adjust themselves to the calcium content of the ration and to conserve the quantity ingested when the supply was limited.

Influence of arsenical dipping on yield of milk by dairy cows, P. T. D. ARNOLD, W. M. NEAL, and R. B. BECKER (*Jour. Dairy Sci.*, 15 (1932), No. 5, pp. 407-412).—In an effort to show the insignificant effect of arsenical dipping used in tick eradication work on milk yields, the Florida Experiment Station maintained records on the station herd during a campaign to eliminate ticks. The cows were dipped in a standard arsenical solution at 14-day intervals from March 1930 to May 1931, except during the months of January, February, and March when 28-day intervals were allowed.

On the basis of 826 cow dips there was a total shrinkage in milk flow of only 1.9 percent, comparing succeeding with previous week's milk yield. The greatest decrease in production was in the second milking after dipping, indicating that the effect was due to arsenic absorption rather than to the shock and excitement of dipping. No tolerance to arsenic developed. The greatest effect of dipping was obtained during the winter months, followed by autumn, summer, and spring. The shrinkage in milk production was 0.2, 3.8, 1.6, and 0.2 percent, respectively, for the first four days following dipping.

The phosphorus partition in the blood of rachitic and nonrachitic calves, F. J. STARE and C. A. ELVEHJEM (*Jour. Biol. Chem.*, 97 (1932), No. 2, pp. 511-524, fig. 1).—Holstein calves were divided into six lots of four head each at the Wisconsin Experiment Station and were fed the same basal rachitogenic ration. Lot 1 received the basal ration only, while the remaining lots received in addition cod-liver oil, aerated cod-liver oil, sunlight, tomatoes plus sunlight, and tomatoes, respectively. The calves were bled when from 8.5 to 9 months old, at which time the calves in lots 1 and 6 were definitely rachitic, while the other lots were in good physical condition.

The experimentally produced rickets caused a decided decrease in inorganic phosphorus, which in turn caused a decrease in the acid-soluble and total

phosphorus. The decrease in total phosphorus was slightly greater than could be accounted for by the change in inorganic phosphorus alone, due to a slight but definite decrease in ester phosphorus and possibly a slight decline in lecithin phosphorus. The difference between total phosphorus and the combined acid-soluble and lecithin fractions was less than 3 to 4 percent in most cases. Remarkably uniform results were obtained for inorganic phosphorus in rickets when analyses were made on whole blood immediately after withdrawal. Supplementing the diet of rachitic calves gradually returned the phosphorus fractions to normal.

The distribution of the phosphorus fractions between the plasma and blood corpuscles from normal and rachitic calves is given in tabular form. Evidence is also presented to show that the analysis of inorganic phosphorus in plasma does not give a complete picture of the total change in the inorganic phosphate fraction during rickets.

A study of the milk, blood, and excreta of cows fed moderate and excessive amounts of irradiated yeast or ergosterol. A. F. HESS, R. F. LIGHT, C. N. FREY, and J. GROSS (*Jour. Biol. Chem.*, 97 (1932), No. 2, pp. 369-377, fig. 1).—Milk from cows fed about 300 g of irradiated yeast daily was found to be highly antirachitic and prevented or cured rickets in infants. While the yeast used had a very high concentration of vitamin B₁, the titer of this vitamin in the milk was not increased. Yeast feeding did not increase the phosphorus, calcium, or ash content of the milk nor the inorganic phosphorus or calcium content of the serum. Feeding excessive nontherapeutic amounts of irradiated ergosterol caused a slight but definite rise in the calcium, phosphorus, and ash content of the milk and a rise in the concentration of calcium and especially of phosphorus in the serum. These increases were less marked in the milk of cows producing a large volume of milk daily. When irradiated yeast was fed in excessive quantities the blood contained about 1 unit of vitamin D per 1.5 g, and the same amounts were found in the blood of cows fed about three times as much irradiated ergosterol.

Cows receiving 300 g of irradiated yeast daily excreted about 25 percent of the vitamin D ingested in the feces, but none was recovered from the urine. Histological examination of various organs showed no lesions on the cellular structure or blood vessels of cows fed excessive amounts of irradiated ergosterol over long periods, and analyses of the bone ash showed the percentages to be within normal limits. It was determined that the lower the daily production of butterfat the higher was the concentration of vitamin D in the fat, and also that the greater the daily production of milk the greater was the total number of vitamin D units in the milk although the units per quart may be lower.

How milk freezes. F. B. BALDWIN, JR., and W. B. COMBS (*Milk Dealer*, 21 (1932), No. 12, pp. 46, 47, figs. 5).—A study was undertaken at the Minnesota Experiment Station to determine the manner in which milk freezes. Shotgun cans and 8-gal. milk cans filled with whole milk were subjected to freezing temperatures under varying conditions. Observations were made by immersing the hand into the milk to feel the ice crystal formation.

The milk fat rose to the top before freezing began. Ice crystal formation began simultaneously under the shoulders of the 8-gal. cans and at the point where the top of the milk and the atmosphere met in the shotgun cans and around the outside of the base of the cans. As freezing progressed ice crystals collected around the first-formed nuclei and began to creep up from the base. At the same time the bottom of the can began to fill with crystals. At no time was ice as thick on the bottom or halfway up the sides as it was around the base or under the shoulders of the can. The cream layer froze, and due to the force exerted by the continued greater concentration of the unfrozen

portion assumed a convex form. A small unfrozen core always remained in the center of the can.

Analyses showed that the frozen part of the milk contained more than twice as much butterfat as the unfrozen portion. The proportion of fat in the frozen milk was high in the cream layer, while that from the sides and bottom contained very small amounts.

Thawing and sampling partially frozen milk, F. B. BALDWIN, JR., and W. B. COMBS (*Milk Dealer*, 22 (1932), No. 1, pp. 54, 56).—The Minnesota Experiment Station undertook a study to determine the proper method of thawing partially frozen milk in order to obtain an accurate sample for butterfat analysis. The whole milk studied was partially frozen in 8-gal. cans in a cold room maintained at from 0° to -10° F. Three methods of thawing this milk were employed: (1) By the injection of direct steam into the can, (2) placing the can in a water bath, and (3) by allowing hot water to run down the sides of the can.

The average time required to thaw the cans of milk by the steam method was less than 1 minute. The butterfat percentage and the specific gravity of the original milk were 3.54 and 1.0309 and for the thawed milk 3.4 and 1.0297, respectively. In a water bath at 70° it required an average of 20 minutes to thaw the cans. The original milk contained 4.4 percent of butterfat and had a specific gravity of 1.0296, while the thawed milk tested 4.37 percent of butterfat and had a specific gravity of 1.03. Where milk was thawed by allowing water at 160° to flow down the sides of the can, it required an average of 5.3 minutes to melt the ice. The butterfat content of the original milk was 4.47 percent and it had a specific gravity of 1.0318. The thawed milk tested 4.46 percent of butterfat and had a specific gravity of 1.0316. These results show that partially frozen milk can be accurately sampled if thawed in the proper manner. When a few cans of such milk are received, thawing by allowing hot water to run down the sides of the cans appeared to be the best method, but where large numbers of cans are received the water bath gives the best results. The application of direct steam to frozen milk should be avoided, not only because of the inaccuracies encountered in sampling but because of the possible effect upon the milk.

Centrifugal separation of partially frozen milk, F. B. BALDWIN, JR., and W. B. COMBS (*Milk Dealer*, 22 (1932), No. 2, p. 43).—Concluding the above studies, experiments were undertaken to determine the effect of partial freezing and thawing of milk upon its efficient separation. Batches of milk were divided into equal parts, one of which was partially frozen in 8-gal. milk cans in a room maintained at from 0° to -10° F., while the other half served as a control. The partially frozen milk was thawed in one of the three manners previously described. After complete thawing, both the control and experimental batches were heated from 90° to 92° and separated in a power separator.

The fat tests of the skim milk showed no significant difference in the butterfat content of the control or partially frozen batches. These results show that partial freezing is not detrimental to efficient centrifugal separation if cream is completely thawed by any of the three methods and properly warmed before separating.

The heat coagulation of milk, I, II (*Jour. Dairy Sci.*, 15 (1932), Nos. 4, pp. 331-343, figs. 3; 5, pp. 345-366, figs. 16).—The U.S.D.A. Bureau of Dairy Industry here reports two studies in a series to determine the factors responsible for variations in the stability of milks to heat.

I. Variations in the compositions, heat stability, and other tests of milks from four cows during the course of a lactation period, G. E. Holm, B. H. Webb, and E. F. Deysher.—The phase of the study reported in this paper dealt

with the extent to which the various tests commonly employed correlated with time of coagulation by heat of both fresh and evaporated milks from four cows throughout a lactation period.

The results showed no marked correlation between heat stability and the various tests and analyses made upon the milk. The so-called "rapid" tests, such as the acid test, the alcohol test, and the phosphate test, sometimes used for classifying milks for condensing, did not satisfactorily indicate the relative heat stability of the milks. The salt balance also showed no direct correlation with the heat stability, nor was the buffer intensity related to the stability. There was no clear relationship between the heat stability of fresh milks and of their evaporated products. The individual milks retained fairly constant values in many of the tests, the values being characteristic of the milk of each cow. The results conclusively demonstrate the inadequacy of the present knowledge of the heat stability of milk.

II. *The influence of various added salts upon the heat stabilities of milks of different concentrations*, B. H. Webb and G. E. Holm.—This phase of the study was undertaken to obtain more detailed information on the effect of different added electrolytes on the heat stability of milks of different concentrations.

In preliminary work it was shown that variations in time of coagulation with variations in the temperatures used were of a logarithmic nature. The variations were less for the 9 than for the 18 percent solids-not-fat milks. Temperatures of from 110° to 120° C. yielded results of greatest practical value, while higher temperatures often produced large errors in the results. The concentration of solids-not-fat was an important factor in forewarming in varying the relative effects. Forewarming at high temperatures lowered the stability of milks of higher solids-not-fat concentration, and this property was not restored by the addition of electrolytes, indicating that forewarming does not affect stability merely through changes in the equilibria of the soluble salts.

The heat stability of an 18 percent solids-not-fat concentration milk could not be predicted from the heat stability of the original milk. It was also found that when phosphates were used as neutralizers they either materially improved stability or did not greatly affect it. It was further confirmed that there are two types of milk, one stabilized by the addition of positively and the other by the addition of negatively charged electrolytes. It was shown that, in the lower concentration, milks were more sensitive to the effect of bi-, tri-, and quadrivalent ions and the monovalent H-ion, while in higher concentrations the monovalent potassium ion was also effective. Data are presented to show the effect of various electrolytes on the two types of milk at 9 and 18 percent solids-not-fat concentrations.

Data show that in studies of coagulation consideration must be given to phase concentration and that conclusions drawn from studies on milk of one concentration are not applicable to milks of different concentrations. At the lower concentrations of solids-not-fat, various electrolytes exhibited critical concentrations or ranges in which their effect was great.

Some observations on the effect of temperature of pasteurization on the acid coagulation of skim milk, L. M. THURSTON and J. L. BAERNHART (*Jour. Dairy Sci.*, 15 (1932), No. 5, pp. 401-405, figs. 3).—In studying the effect of temperature of pasteurization on the manufacture of cottage cheese, the West Virginia Experiment Station observed that coagulation by culture-developed lactic acid occurred noticeably sooner when skim milk was pasteurized for 30 minutes at 85° C. (185° F.) than when pasteurized for the same period at 62.8° C. A test was, therefore, planned to determine the effect of pasteurizing

temperature on the time required for coagulation and on the curd tension, total acid developed, and pH concentration at the time of coagulation.

When the temperature of pasteurization was varied the curd tension, at the time a jelly-like curd was first formed, was roughly twice as great for raw skim milk and skim milks pasteurized at 62.8°, 68.3°, and 73.9° as for those pasteurized at 79.4° and 85°. The pH concentration and the total acids present were decreased slightly as the pasteurizing temperature increased up to 68.3°, but above this point the changes were more marked. The time required for coagulation changed but little as the temperature increased up to 68.3°, but was reduced materially at 73.9°, beyond which there was little further change.

The coli-aerogenes determination in pasteurization control, M. H. McCREADY and E. LANGEVIN (*Jour. Dairy Sci.*, 15 (1932), No. 4, pp. 321-329).—Based on the results of two series of studies from large as well as from small milk plants, the Provincial Bureau of Health of Quebec concluded that plate counts as a laboratory method of pasteurization control were not adequate and that supplementary laboratory methods were desirable. The supplementary method that seemed to give the most reliable control was coli-aerogenes determination. This recommendation was made because this organism is seldom found in properly pasteurized milk, because the addition of even small numbers of coli to such milk can be easily detected, and because coli readily become established and multiply in traces of milk in the more dangerous types of defects and on unsterilized surfaces of pasteurizing equipment. It was shown that milk could be delivered to the consumer containing coli in not more than from 10 to 20 percent of the 1 cc portions tested.

The B. coli content of raw and pasteurized milk, A. J. SLACK and C. W. MADDEFORD (*Canad. Pub. Health Jour.*, 23 (1932), No. 12, pp. 574-578).—The Institute of Public Health, London, Ontario, made a study of the *Bacillus coli* content of various grades of milk under market and controlled laboratory conditions.

It was shown that laboratory methods for the control of pasteurizing plants must be simple enough so that tests could be reported within from 24 to 48 hours. While the absence of typical colon bacilli was not necessarily an indication of proper pasteurization, or even that the milk had been pasteurized, the presence of the organisms in small volumes of pasteurized milk indicated some fault in pasteurizing, cooling, or bottling the milk. The results showed that milk having colon bacilli in 0.1 cc amounts either was improperly pasteurized or contaminated subsequent to pasteurization.

Studies on *Lactobacillus thermophilus*, D. B. CHARLTON (*Jour. Dairy Sci.*, 15 (1932), No. 5, pp. 393-399).—In the routine bacteriological analyses of the Corvallis, Oreg., milk supply a higher bacterial count was noticed for the pasteurized milk of one plant than in the raw milk delivered to the plant. Further study led to the isolation of a *L. thermophilus* which agreed in almost every respect with the original description, but for which additional characteristics were recorded. This organism grew poorly on the nutrient agar used in routine platings, and the indistinct filamentous colony was sometimes pin point in size. However, the colony could be easily distinguished from the pin-point colonies of thermoduric streptococci. The organism grew better on Bacto-Proteose peptone than on ordinary peptone. The peculiar growth requirements and the relatively short period of viability characteristic of the organism, together with the fact that it is of rather uncommon occurrence, probably explains why it has not been more frequently isolated.

Is loose milk a health hazard? S. FLEXNER ET AL., edited by E. F. BROWN and L. SPENCER (*New York: Dept. Health, Milk Comm.*, 1931, pp. XV+254,

[figs. 40]).—In this report the Milk Commission of New York City points out the dangers to public health as a result of the sale of loose milk. The results of laboratory tests are given in support of the conclusion that this method of dispensing milk should be gradually done away with. A historical account is given of the progress that has been made in securing a pure milk supply for New York City. The regulations governing the production of the various grades of milk are also presented.

Substances adsorbed on the fat globules in cream and their relation to churning.—I, *The churnability of artificial emulsions prepared with the known emulsifying agents of cream*, H. F. WIESE and L. S. PALMER (*Jour. Dairy Sci.*, 15 (1932), No. 5, pp. 371–381).—In studies at the Minnesota Experiment Station fresh buttermilk, calcium caseinate, serum globulin, lactalbumin, and a crude egg yolk phospholipid were used as emulsifying agents in order to ascertain whether some of these materials might constitute the sole fat stabilizer in cream. In preparing the butterfat emulsions sufficient melted filtered butterfat to yield a 4 percent milk was added to a 1 percent dispersion of the emulsifier at 100° F. This mixture was homogenized, separated, standardized to 30 to 35 percent butterfat, and churned. Each butter was worked slightly, and then the type of emulsion present in the churned product was determined under the microscope.

It was found that fresh buttermilk contained a substance or substances having the ability to stabilize oil-in-water emulsions. It was probable that part of this material came from the surface of the fat globules during churning. The butterfat-in-buttermilk dispersion resembled whole milk in general appearance, microscopic structure, cream separation, and churnability. Stable emulsions of butterfat were prepared in dispersions of calcium caseinate, lactalbumin, globulin, and phospholipid. Such emulsions resembled whole milk in general appearance, formation of cream layer, and microscopic structure, but each showed an abnormal behavior either on separation or in churnability of cream. The best separation was obtained with the phospholipid emulsion and the best churning with the lactalbumin emulsion. These results indicate that no one of the milk constituents used behaved entirely like normal cow's milk. It also appeared that not one of the substances tested constituted the sole material adsorbed on the surface of the fat globules.

Cheese-ripening studies: Nitrogen requirements of lactic acid bacteria, I, II (*Canad. Jour. Res.*, 7 (1932), No. 4, pp. 364–369; 370–377).—Investigations previously noted (*E.S.R.*, 68, p. 242) were continued.

I. *The fractional analysis of various nitrogen sources used for the quantitative determination of the sugar-fermenting abilities of lactic acid bacteria*, B. A. Eagles and W. Sadler.—Using the method of Wasteneys and Borsook (*E.S.R.*, 52, p. 803), the nitrogen distribution was determined in nitrogen sources available commercially and in sources that could readily be prepared in the laboratory. Analyses showed that peptic casein digest broth contained from 55 to 63 percent of protein nitrogen, from 19 to 25 percent of peptone nitrogen, and from 14 to 17 percent of subpeptone nitrogen, according to the particular casein used. When less casein was used for digestion or the period of digestion was reduced, the total amount of nitrogen made available was lower, particularly with the subpeptone nitrogen fraction. With tryptic casein digest broth 70 percent of the nitrogen was in the subpeptone nitrogen fraction and about 28 percent in peptone nitrogen.

When the nitrogen sources tested were used in fermentation studies their suitability as a source was not always fully indicated by the nitrogen distribution picture, but the biological significance of the nitrogen distribution was usually

reflected in the influence on the sugar-fermenting abilities of the lactic acid bacteria.

II. *The influence of defined nitrogen sources on the sugar-fermenting abilities of lactic acid bacteria*, W. Sadler, B. A. Eagles, and G. Pendray.—The influence of 36 nitrogen sources on the sugar-fermenting abilities of five cultures isolated from cheese was investigated. The cultures were a gram-positive coccus that failed to liquefy gelatin, and the sugars glucose, mannose, and lactose were used in this work. The suitability of the nitrogen source was determined in terms of total titratable acidity produced by the organisms from defined sugars after 14 days' incubation at appropriate temperatures.

Peptic casein digest broth was a suitable source of nitrogen for each organism when prepared by the standard method and when the total nitrogen content of the broth was approximately 1 percent. Diluting the broth to 0.5 percent of total nitrogen usually reduced the titratable acidity obtained by one third. Tryptic casein digest broth containing approximately 1 or 0.5 percent of total nitrogen was unsuitable as a nitrogen source for two of the organisms, but at the 0.5 percent level was very suitable for the remaining organisms.

A broth prepared from a commercial peptone was a suitable source of nitrogen for all the organisms, but another commercial peptone, apart from the fermentation of mannose by two strains of organisms, was no more suitable than peptic casein digest broth containing 0.5 percent of total nitrogen. In a commercial hydrolyzed casein broth the nitrogen distribution gave a somewhat composite picture of the distribution in peptic and tryptic casein digest broth and was not suitable for cultures of all strains of organisms. The hydrolyzed casein broth containing 1 percent of total nitrogen was more suitable for the cultures in which it could be used than the same broth diluted to contain 0.5 percent of nitrogen.

By using certain of the nitrogen sources it was possible to differentiate between some of the groups of organisms studied. The results of the fermentation studies clearly show that if the "kind" of nitrogen made available is suitable the "amount" of nitrogen supplied is then equally important.

Methods for use in the bacteriological examination of dry milk and related powders, P. A. DOWN ET AL. (*Jour. Dairy Sci.*, 15 (1932), No. 5, pp. 383-389).—A report is submitted by the subcommittee on bacteriological methods of examining condensed, evaporated, and dry milk of the American Dairy Science Association giving an outline for making bacteriological examinations of dry milk and certain related powdered baby foods. The methods presented in this paper will be revised in accordance with the suggestions received before they are finally adopted.

Note on use of alkaline water blanks for plating dried milk products, P. S. PRICKETT and N. J. MILLER (*Jour. Dairy Sci.*, 15 (1932), No. 5, pp. 391, 392).—Because considerable difficulty has been encountered in counting bacterial colonies on plates prepared from dried milk products, due to tiny particles of undissolved protein, the authors made a study of methods to eliminate this difficulty without materially affecting the counts. More than 20 different alkaline solutions were tested upon various kinds of dried milk products. The best results were obtained with lithium hydroxide solutions, and such solutions showed no germicidal action. Counts obtained when $M/5$ and $M/10$ lithium hydroxide dilution blanks were used compared very favorably with parallel counts obtained with distilled water dilution blanks. With powdered milk products of low pH value the $M/5$ lithium hydroxide dilution seemed to give best results, while the $M/10$ dilution gave best results when the pH value was high. Since the fat had a tendency to churn out of these dilution blanks, excessive shaking of powdered milk dilutions should be avoided.

The viability of *Lactobacillus acidophilus* as affected by freezing in a sherbet mixture. C. C. PROUTY and H. A. BENDIXEN (*Jour. Dairy Sci.*, 15 (1932), No. 5, pp. 413-419).—At the Washington College Experiment Station an effort was made to increase the viability of *L. acidophilus* milk by preparing it in the form of a sherbet. A total of 28 such sherbets were made up, using four strains of *L. acidophilus* in their preparation. A study was made of the number of viable organisms remaining after 1, 2, 3, 5, and 7 days' storage at temperatures below -17° C.

The number of organisms in the sherbets carrying one strain of *L. acidophilus* were reduced to a few million per cubic centimeter after 5 days' storage, while under similar conditions several hundred million viable organisms were usually present in sherbets made with the other strains. Variations in viability also occurred in cultures of the same strain. It was found that a more rapid reduction of organisms occurred in the sherbets with the higher titratable acidity. Variations in sugar concentration caused no significant variation in the viability of the organisms. It was concluded that it is possible to prepare sherbets containing large numbers of viable *L. acidophilus* organisms after from 5 to 7 days' storage at temperatures below -17° when the more resistant strains having a high initial count are used in the manufacture and the titratable acidity of the sherbet is not permitted to exceed 1 percent.

Manufacturing chocolate ice cream: A study of its problems. S. L. TUCKEY, P. H. TRACY, and H. A. RUEHE (*Ice Cream Trade Jour.*, 28 (1932), No. 8, pp. 39-43).—Continuing this study (E.S.R., 64, p. 874) at the Illinois Experiment Station, it was shown that adding cold unhomogenized sirup to an unaged mix prolonged the whipping period when compared with an unaged mix. Homogenization of only the sirup had no appreciable effect on the whipping properties of the mix. Homogenization or aging the sirup with the mix gave the best whipping properties. Adding aged sirup to the mix at the freezer prolonged the freezing period. While all the constituents of cocoa sirup had a detrimental effect on whipping quality, the nonfatty material appeared to exhibit the greatest influence.

Both natural and Dutch process cocoas of high quality were satisfactory for making chocolate ice cream. Chocolate liquors tended to slow up the whipping of mixes more than the cocoa powders. A desirable flavor and color of ice cream was obtained by using three-fourths chocolate liquor and one-fourth cocoa.

VETERINARY MEDICINE

A compendium on the infectious diseases of animals. C. H. STANGE (*Ames: Iowa State Col.*, 1932, pp. [4]+137+[4]).—This mimeographed compendium deals with acute general infectious diseases (pp. 1-89), chronic infectious diseases (pp. 90-127), and infectious diseases caused by protozoa (pp. 128-137).

[Report of work in animal pathology by the Florida Station] (*Florida Sta. Rpt.* 1932, pp. 51, 54, 55).—The work under way here referred to (E.S.R., 67, p. 596) includes that with paralysis of the domestic fowl, by E. F. Thomas, and anaplasmosis in cattle, by D. A. Sanders.

[Report of work in Kansas in animal pathology and parasitology] (*Kansas Sta. Bien. Rpt.* 1931-32, pp. 100-108, 109, 110-113).—The work reported upon (E.S.R., 64, pp. 873, 880) includes that with losses of baby pigs and with cornstalk disease, by R. R. Dykstra and H. F. Lienhardt; abortion disease, by C. H. Kittelman and Lienhardt; blackleg, by J. P. Scott; shipping fever, by Dykstra, Lienhardt, Scott, and H. Farley; anaplasmosis, by Dykstra, C. A. Pyle, and Lienhardt; poultry diseases, by L. D. Bushnell and C. A. Brandy; histopathology of poultry diseases, by Lienhardt; and parasites (*Ascaridia*

lineata Schneid.), resistance of chickens to parasitism as affected by vitamin A, vitamin B, skim milk, blood loss, and worm infestations, and the embryology of *Onchocerca cervicalis*, all by J. E. Ackert.

Epizootic abortion and undulant fever: An epizootic-epidemiologic study, E. HENRICSSON (*Epizootischer Abortus und Undulantfieber: Eine Epizootologisch-epidemiologische Studie*. Stockholm: Staatl. Bakt. Lab., 1932, pp. XV+203, figs. 32; rev. in *Cornell Vet.*, 22 (1932), No. 4, pp. 387, 388).—Part 1 of this contribution from the Government bacteriological laboratory at Stockholm consists of an introduction (pp. 1-9), part 2 considers other views of epizootic abortion (pp. 10-21), part 3 the appearance and spread of epizootic abortion in Sweden (before 1859, from 1859 to 1930) (pp. 22-54), part 4 bacteriological and serological diagnosis (pp. 55-83), part 5 modes of dissemination of epizootic abortion (pp. 84-131), part 6 undulant fever and epizootic abortion (pp. 132-161), and part 7 prophylaxis of epizootic abortion and of undulant fever (pp. 162-185). Part 8 consists of appendixes (pp. 187-196), and part 9 of a bibliography (pp. 197-203).

Identity of the viruses causing "mad itch" and pseudorabies, R. E. SHORE (*Soc. Expt. Biol. and Med. Proc.*, 30 (1932), No. 3, pp. 308, 309).—In continuation of the studies previously noted (E.S.R., 65, p. 872), the author found that serum from swine that had recovered from either "mad itch" or pseudorabies neutralized both viruses. This has led to the conclusion that the inciting agents of both infections are immunologically identical. The differences in the experimental disease produced by the two viruses, one of which was obtained from a cow in Iowa and the other received from A. Aujeszky of Budapest, Hungary, must be considered only as variations induced by two strains of the same virus.

[Contributions on parasitology] (*Jour. Parasitol.*, 18 (1931), No. 2, pp. 113, 114, 115, 116, 117, 118, 119, 121, 122, 124, 125, 126, 127, 128, 130, 131, 133).—Abstracts of contributions presented at the annual meeting of the American Society of Parasitologists, held at New Orleans, La., in December 1931, include the following: Yeast as a Factor in the Growth of the Fowl Nematode *Ascaridia lineata* (Schneider), by J. E. Ackert and T. D. Beach (p. 113); Viability of the Eggs of the Fowl Nematode *Ascaridia lineata* (Schneider) Exposed to Natural Climatic Factors, by J. E. Ackert and G. E. Cauthen (p. 113); Effects of Periodic Bleeding on the Resistance of Chickens to the Intestinal Nematode *Ascaridia lineata* (Schneider), by J. E. Ackert and D. A. Porter (p. 114); Life History of the North American Lung Fluke of Mammals, by D. J. Ameel (p. 114); Two Species of Coccidia [*Eimeria miyarii* Ohira and *E. separata* n. sp.] from the Norway Rat, by E. R. Becker and P. R. Hall (p. 115); Host Feeding in Its Relation to Parasite Reproduction in Avian Malaria, by G. H. Boyd (p. 115); Clinical Experiences with Hexylresorcinol against *Ascaris*, Hookworm, *Trichuris*, *Enterobius*, and *Taenia*, by H. W. Brown (p. 116); Susceptibility and Resistance in Helminthic Infestations, by A. C. Chandler (p. 116); Some Peculiar Relationships between Ectoparasites and Their Hosts, by H. E. Ewing (p. 117); The Seasonal Life History of *Anopheles maculipennis* with Reference to Humidity Requirements and "Hibernation", by S. B. Freeborn (p. 118); A Survey of Flies, Pigs, Fowls, Rats, and Mice in a Rural Community for the Intestinal Protozoa of Man, by W. W. Frye and H. E. Meleney (p. 118); A Pathogenic Nematode [*Neoelectana glaseri*] of the Japanese Beetle, by R. W. Glaser (p. 119) (E.S.R., 66, p. 559); Some Studies on the Breeding Media, Development, and Stages of the Eye Gnat *Hippelates pustio* Loew (Diptera: Chloropidae), by D. G. Hall (p. 119) (E.S.R., 68, p. 789); A Comparative Study of the Eggs of Californian Anophelines [*Anopheles macul-*

pennis Meig., *A. punctipennis* Say, and *A. pseudopunctipennis* Theob.], by W. B. Herms and F. M. Frost (p. 121); Effect of Five Species of Elmeria upon Egg Production of Single Comb White Leghorns, by W. T. Johnson (p. 122); A New Species of Tick [*Dermacentor halli*] from the Texas Peccary, by A. McIntosh (p. 124); The Effects of Coccidiosis upon the Weights of Chickens Inoculated during the 7th, 12th, and 13th Weeks (p. 125) and Preliminary Results in the Treatment of Coccidiosis in Chickens with Powdered Buttermilk (pp. 125, 126), both by R. L. Mayhew; The Life History of *Leucocytozoon anatis* Wickware, by E. C. O'Roke (p. 127); (see p. 281); The Prevalence of Human Infection with *Trichinella spiralis*, by F. B. Queen (p. 128); Some Effects of Splenectomy on the Blood of Carriers of Anaplasmosis, by C. W. Rees (p. 128); A Study of the Eggs of *Moniezia expansa*, by J. W. Scott and R. F. Honess (p. 130); The Development of *Ocrophagostomum longicaudum* in the Pig, by L. A. Spindler (pp. 130, 131); and Production of Sterile Maggots [*Lucilia sericata* and *Phormia regina*] for Surgical Use, by G. F. White (p. 133).

[Contributions on parasitology] (*Jour. Parasitol.*, 19 (1932), No. 2, pp. 156, 157, 159, 160, 161, 170, 174, 176, 177, 178, 179, 180).—Abstracts of contributions presented at the annual meeting of the American Society of Parasitologists, held at Atlantic City, N.J., in December 1932, include the following: Detection of Proteins of *Haemonchus contortus* in Sera of Infected Sheep and Goats, by J. E. Stumberg (pp. 156, 157); Fatal Infections of *Trichostrongylus colcaratus* in Rabbits, by M. P. Sarles (p. 157); Age Resistance of Chickens to the Parasite *Ascaridia lineata*, by J. E. Ackert, D. A. Porter, and T. D. Beach (p. 157); Resistance to Infestation with *Trichinella spiralis* in Hogs, by G. W. Bachman and R. Rodriguez-Molina (pp. 159, 160); Pathogenicity of Metacercariae of *Nanophyetus salmincola* Chapin for Fish Hosts, by B. T. Simms (p. 160); Immunity to Coccidiosis in Chickens Produced by Inoculation Through the Ration, by W. T. Johnson (pp. 160, 161); Seasonal Incidence and Concentrations of Sand Fly Larvae in Salt Marshes (Culicoides), by J. B. Hull, W. E. Dove, and D. G. Hall (p. 170); Production of Sterile Maggots for Surgical Use—II, Disinfection with Sodium Hydroxide Followed by Formalin, by G. F. White (p. 170) (see above); A Species of Cephalogonimus from the Domestic Duck, by C. H. Alvey (p. 174); The Behavior of the Avian Malarias in the Common Fowl, an Abnormal Host, by R. D. Manwell (p. 176); The Control of *Leucocytozoon anatis* Wickware, by E. C. O'Roke (p. 177); Control of Poultry Coccidiosis by Chemical Treatment of Litter, by J. Andrews (p. 177); Relapse and Associated Phenomena in the Haemoproteus Infection of the Pigeon, by G. R. Coatney (p. 178); The Influence of an Increased Burden of Phagocytosis upon Malarial Infections of Birds, by W. Gingrich (pp. 178, 179); The Cytology of *Leucocytozoon anatis* Wickware—I, Gametogenesis, by R. K. Martin (p. 179); Additional Observations on the Use of Fouadin in the Treatment of *Dirofilaria immitis* Infestation in the Dog, by P. C. Underwood and W. H. Wright (p. 180); and Studies of Bovine Coccidiosis, by C. W. Rees (p. 180).

[Contributions on parasitology] (*Jour. Parasitol.*, 19 (1933), No. 3, pp. 242, 243, 244-246, 248, 249, 251, 252, 253, 254, fig. 1).—Contributions presented at the meetings of the Helminthological Society of Washington held in 1932 include the following: The Experimental Transmission of the Swine Lungworm *Metastrongylus elongatus* to Dogs, by J. E. Alicata (p. 242); Failure of Repeated Injections of Trichina Extracts [*Trichinella spiralis*] to Immunize Rats to Trichinosis, by J. T. Lucker (p. 243); The Dung Beetle *Ataenius cognatus* as the Intermediate Host of *Hymenolepis cantaniana*, by J. E. Alicata and M. F.

Jones (p. 244); A New Intermediate Host [*Parosys clavuliger* Serv.] for *Ochlospirura hamulosa*, the Gizzard Worm of Poultry, by E. Cuvillier (pp. 244, 245); Two New Intermediate Hosts [*Onthophagus janus* and *O. pennsylvanicus*] for the Poultry Cestode *Hymenolepis carloca*, by E. Cuvillier and M. F. Jones (p. 245); A New Species of *Tetrameres* [*T. pattersoni*] from the Bobwhite, by E. B. Cram (pp. 245, 246); A Nematode, *Setaria labiato-papillosa*, from the Udder of a Cow (p. 246), *Onchocerca gutturosa* from the Cervical Ligament of Cattle in Puerto Rico (p. 246), and *Onchocerca flexuosa* from the Subcutaneous Tissues of an Antelope and from Subcutaneous Abscesses of a Deer (p. 246), all by G. Dickmans; A Second Record of the Occurrence of *Gongylonema* in Deer, by J. T. Luckner (pp. 248, 249); A Note on *Oystercercus ovis*, by P. C. Underwood (p. 251); A Case of Heavy Ascarid [*Ascaris equorum*] Infestation in a Colt, by P. C. Underwood and E. E. Wehr (pp. 251, 252); Further Notes on the Life History of *Gastrophilus intestinalis* (p. 252) and Occurrence of *Ascaridia lineata* in California Valley Quail (p. 252), both by E. E. Wehr; The Occurrence of *Stephanurus dentatus* in Northern United States, by J. E. Alicata (p. 253); and Comparative Data Relative to Incidence of Worm Parasites in Confined and Non-confined Chickens, by E. Cuvillier and M. F. Jones (p. 254).

Bibliography of helminthology for the year 1931, compiled by A. WALTON (St. Albans, Eng.: Imp. Bur. Agr. Parasitol., 1932, pp. 81).—In this bibliography of helminthology for 1931 (E.S.R., 68, p. 363), the contributions in 425 publications are listed and an author index included.

On the prophylactic action of vitamin A in helminthiasis, P. A. CLAPHAM (Jour. Helminthol., 11 (1933), No. 1, pp. 9-24).—In experiments conducted with a view to determining the action of vitamin A in the prophylaxis of helminthiasis, *Heterakis gallinae* in the chicken and *Parascaris equorum* in albino rats were used. The findings indicate that in *Heterakis* infestation the vitamin content of the diet has no effect on the course of the infestation. In ascariasis in rats, however, the vitamin affects significantly the hatching, survival, and rate of development of the larvae within the host.

A list of 33 references to the literature is included.

Helminths and coccidia from Ohio bobwhite, C. VENARD (Jour. Parasitol., 19 (1933), No. 3, pp. 205-208).—This is a report of examinations made of the helminth and coccidial parasites found in 67 adult Ohio bobwhites (*Colinus virginianus virginianus* L.) shot on the wing in the field, 5 species of nematodes, fragments of cestodes probably of the genus *Hymenolepis*, and 3 species of coccidia, namely, *Eimeria dispersa* Tyz., *E. tenella* R. & L., and *E. acervulina* Tyz., having been found. Of the 3 species of coccidia discovered, only *E. dispersa* had previously been reported from this host. *E. tenella* was successfully transmitted from the bobwhite to the chicken. The nematodes were *Dispharynx spiralis* (Molin), *Scurocyrnea colini* (Cram), *Heterakis gallinae* (Gmel.), *H. bonasae* (Cram), and *Subulura strongylina* (Rud.).

Cross-infection experiments with coccidia of rodents and domesticated animals E. R. BECKER (Jour. Parasitol., 19 (1933), No. 3, pp. 230-234).—The author finds that "the rat, even when quite young, is not susceptible to infection with *Eimeria magna* of the rabbit, *E. scabra*, *E. debilecki*, and *E. perminuta* of the pig, *E. faurei* of the sheep, *E. smithi* of the ox, *E. caviae* of the guinea pig, and *E. tenella* and *E. maxima* of the chicken. The rat coccidia, *E. mitacriti* and *E. separata*, are not infective to mice, even when they are quite young, cottontail rabbits, guinea pigs, and striped ground squirrels.

"A previously unreported interspecific cross-infection is possible—*E. magna* Péreard from the Belgian hare (*Lepus cuniculi*) can complete its development

and produce pathological symptoms and even death in the North American cottontail rabbit (*Sylvilagus floridanus mearnsi*). *E. separata* and *E. miyairii* obtained from the wild Norway rat, *Epemys norvegicus*, can be successfully cultivated in the albino rat, derived originally, of course, from the Norway rat. A number of other attempted cross-infections resulted negatively."

Occurrence of *Coccidioides immitis* in lesions of slaughtered animals. M. D. BECK (*Soc. Expt. Biol. and Med. Proc.*, 26 (1929), No. 6, pp. 534-536).—During the course of an epidemiological investigation of coccidial granuloma in Kern County, Calif., in which 38 specimens from slaughtered animals were examined during a period of 3 months, lesions from 6 cattle and 1 sheep were proved to be due to *C. immitis*. The author considers it improbable that humans are infected from such animals, but rather that both man and animals are infected from the same source.

A contribution to actinomycosis caused by the *Actinobacillus* (actinobacillosis), B. LIEBSTER (*Beitrag zu der durch den Actinobazillus Verursachten Actinomycose (Actinobazillose)*). *Inaug. Diss.*, *Vet. Hyg. Inst., Univ. Leipzig*, 1932, pp. 28).—This account is presented in connection with a review of the literature, of which a list of 32 references is included.

A method of preserving *Actinomyces bovis* in its "ray fungus" form, I. A. MERCHANT (*Jour. Amer. Vet. Med. Assoc.*, 82 (1933), No. 4, pp. 630, 631, fig. 1).—The author has found that the best preservative for this purpose is a concentrated sugar solution prepared by dissolving 1 lb. of granulated sugar in 12 oz. of distilled water. By immersing a bottle containing the ingredients in hot water solution is hastened. A 1 percent solution is added as a preservative. "Equal parts of exudate from the actinomycotic lesion and sugar solution are thoroughly mixed. The mixture is placed in a bottle which can be sealed tightly. The micro-organisms in the exudate which has been preserved by this method and kept at room temperature for 4 years, appear like those present in fresh exudate."

The experimental transmission of anaplasmosis by *Dermacentor andersoni*, C. W. REES (*Parasitology*, 24 (1933), No. 4, pp. 569-573).—This is an account of investigations conducted at Jeanerette, La., which have shown that anaplasmosis in cattle may be transmitted by the Rocky Mountain spotted fever tick as previously announced (*E.S.R.*, 67, p. 597).

It was found that "(1) larvae may acquire the infection by engorging on a bovine whose blood contains anaplasms and may transmit the infection as nymphs to susceptible bovines and (2) in a similar manner the nymphs may acquire the infection and transmit it as adults. The test of 'hereditary' transmission was negative, i.e., the larvae did not apparently acquire the infection from adult females which engorged on carriers of anaplasmosis. Conditions of transmission by *D. andersoni* are the same as those which have thus far been determined by me for *D. variabilis* [*E.S.R.*, 67, p. 311]. The incrimination of these two species of tick points to the possibility that anaplasmosis occurring anywhere within the known range of distribution of that disease in the United States may be tick borne so far as a coincident distribution of known tick carriers can establish this possibility."

Relation of vitamin "B" to infection and immunity with special reference to *Bacillus welchii*, W. B. ROSE (*Soc. Expt. Biol. and Med.*, 25 (1928), No. 8, pp. 657, 658).—The author considers the work reported to indicate that nutritional factors deserve important consideration in immunologic studies, and that vitamin B in particular merits special attention.

Borrellelotoses: Fowl-pox, molluscum contagiosum, variola-vaccinia, E. W. GOODPASTURE (*Science*, 77 (1933), No. 1987, pp. 119-121).—The generic

name *Borrelliota* is proposed by the author for the specific coccoid granules first described by A. Borrel² as the actual virus of fowl pox. Later investigators have shown these to constitute the essential component of the cellular inclusions and to be fractionally infective, filtrable, and specifically agglutinable by immune serum.

The terminology proposed includes *Borrelliota variolae hominis*, specific corpuscles of smallpox (Paschen bodies, elementary corpuscles); *B. variolae bovis*, specific corpuscles of vaccinia (Paschen bodies, elementary corpuscles); *B. variolae equi*, specific corpuscles of horsepox; *B. variolae porci*, specific corpuscles of swine pox; *B. variolae ovium*, specific corpuscles of sheep and goat pox; *B. mollusci*, specific corpuscles of molluscum contagiosum (Lepeschütz corpuscles); and *B. avium*, specific corpuscles of fowl pox (Borrel corpuscles).

Studies on the dissociation of the *Brucella* group. W. L. MALLMANN and F. GALLO (*Jour. Agr. Res. [U.S.]*, 46 (1933), No. 3, pp. 267-279, pl. 1).—Following a historical review, the authors give the history of the cultures studied and report experimental work carried on at the Michigan Experiment Station.

In the course of the work "rough forms of *Brucella* were obtained by aging on liver-infusion agar slants, followed by further aging in nutrient veal broth. The rough forms of *Brucella* studied were similar to pure-line rough strains of the paratyphoid group. Classification of S forms of *Brucella* by dye plates and hydrogen sulfide production does not hold for rough forms. Rough forms of *Brucella* were changed to S type by passage through guinea pigs. The value of typing S forms of *Brucella* by dye plates and hydrogen sulfide is confirmed by the return of R types to their original groups by these two methods."

Undulant fever: An epidemic of subclinical infection with *Brucella*. P. DOOLEY (*Arch. Int. Med.*, 50 (1932), No. 3, pp. 373-379, fig. 1).—The blood of 41 percent of 263 individuals using infected raw milk, obtained from a herd of about 100 Holstein cows in which there had previously been an epidemic of infectious abortion, was found to contain *B. abortus* agglutinins.

The identity of *C. oedematoides* and *B. sordellii*. F. HUMPHREYS and F. L. MELENEY (*Sci. Expt. Biol. and Med. Proc.*, 25 (1928), No. 7, pp. 611-614).—The authors conclude that *Clostridium oedematoides*, described by Meleney, Humphreys, and Carp (*E.S.R.*, 62, p. 260), is identical with the putrefactive pathogenic anaerobe *Bacillus oedematis sporogenes*, named and described by A. Sordelli in 1923³ and redescribed by Hall and Scott in 1927 as *B. sordellii* (*E.S.R.*, 62, p. 261), which stands by priority over *C. oedematoides*.

The serological identity of strains of *Erysipelothrix rhusiopathiae* of ovine and porcine origin. H. MARSH (*Jour. Amer. Vet. Med. Assoc.*, 82 (1933), No. 4, pp. 584-586).—The results obtained in investigations at the Montana Experiment Station are considered to show clearly that the three strains of *E. rhusiopathiae* (one from a Montana lamb, one from a New Zealand lamb, and one from a case of swine erysipelas) are serologically identical as far as agglutinins are concerned.

***Limnea viatrix* d'Orb. infected by cercariae of *Fasciola hepatica* at Buenos Aires** [trans. title], J. BACIGALUPO (*Compt. Rend. Soc. Biol. [Paris]*, 111 (1932), No. 38, p. 828).—The snail *L. viatrix* has been found to be the natural intermediate host of the liver fluke (*F. hepatica*) in Argentina.

The tenacity of foot-and-mouth disease virus in milk and dairy products, I, II [trans. title], F. TERBRÜGGEN (*Deut. Tierärztl. Wchnschr.*, 40 (1932), Nos. 9, pp. 129-134; 34, pp. 529-533).—A report of studies, the details of which are presented in tabular form. Lists of 28 references to the literature are included.

² *Compt. Rend. Soc. Biol. [Paris]*, 57 (1904), pp. 642, 643.

³ *Compt. Rend. Soc. Biol. [Paris]*, 89 (1923), No. 19, pp. 53-55.

Investigations on the diseases of the Psittacidae [trans. title], G. PACHECO (*Mem. Inst. Oswaldo Cruz*, 26 (1932), No. 2, pp. 169-233, pls. 4, fig. 1; *Eng. abs.*, pp. 230-233).—This is a report upon observations of diseases of the Psittacidae liable to be confused with the psittacosis of parrots.

Diagnostic significance of precipitin tests with Anderson phosphatide fractions from human, bovine, and avian tubercle bacilli, C. A. DOAN (*Soc. Expt. Biol. and Med. Proc.*, 26 (1929), No. 8, pp. 672-677).—A contribution from the Rockefeller Institute for Medical Research in New York.

Culturing bovine tubercle bacilli, M. EVANOFF and H. C. SWEANY (*Soc. Expt. Biol. and Med. Proc.*, 26 (1929), No. 6, p. 456).—In this contribution a direct culture method for obtaining growth and identifying tubercle bacilli from bovine material is described. The bovine organisms isolated grow directly on cream-egg-milk medium, but not on glycerin-egg-milk medium. Direct inoculation and treatment with 3 percent hydrochloric acid and 3 percent sodium hydroxide are recommended for more complete results.

The occurrence of tubercle bacilli in eggs [trans. title], M. KLIMMER (*Berlin. Tierärztl. Wchnschr.*, 48 (1932), No. 46, pp. 737-739).—In a review of the literature, a list of 17 references to which is included, the author has found that of 1,333 eggs from tuberculous hens 5.7 percent contained tubercle bacilli. Of these 1.4 percent were detected through cultures and animal inoculations and 4.2 percent microscopically.

A natural infection of the sharp-tailed grouse and the ruffed grouse by Pasteurella tularensis, R. G. GREEN and J. E. SHILLINGER (*Soc. Expt. Biol. and Med. Proc.*, 30 (1932), No. 3, pp. 284-287).—The authors here record the isolation of *P. tularensis* from a sharp-tailed grouse (*Pediocetes phasianellus*) and from a ruffed grouse (*Bonasa umbellus togata*) in Minnesota, made during the course of routine examinations and study of game birds collected in various areas of the State in the fall of 1932.

A natural infection of quail by B. tularensis, R. G. GREEN and E. M. WADE (*Soc. Expt. Biol. and Med. Proc.*, 26 (1929), No. 7, pp. 626, 627).—The presence of *B[acterium] tularensis* in one bird of a covey which apparently was afflicted with disease and was known to be diminishing in size would indicate tularemia as the probable destructive factor, confirming the work of Parker previously noted (*E.S.R.*, 61, p. 871).

Experimental tularemia in muskrats, R. G. GREEN, E. M. WADE, and E. T. DEWEY (*Soc. Expt. Biol. and Med. Proc.*, 26 (1929), No. 6, pp. 426, 427).—The authors have found the muskrat to be very susceptible to an experimental infection with *B[acterium] tularensis*. The pathology produced by the infection is similar to that seen in rabbits and guinea pigs, but the lesions in the muskrat are apt to be more marked. It is indicated that tularemia may occur in nature as a disease of muskrats.

Experimental tularemia in birds, R. G. GREEN and E. M. WADE (*Soc. Expt. Biol. and Med. Proc.*, 25 (1928), No. 8, p. 637).—Preliminary experiments indicate that the Hungarian partridge (see *E.S.R.*, 60, p. 673) is highly susceptible to tularemia, a fatal infection resulting from an open inoculation of a skin abrasion. The pigeon and the ring-necked pheasant appear to be relatively more resistant to tularemia. The domestic fowl appears to be absolutely resistant to the disease.

Experimental tularemia in ring-necked pheasant, R. G. GREEN, E. M. WADE, and W. KELLY (*Soc. Expt. Biol. and Med. Proc.*, 26 (1928), No. 3, pp. 260-263).—The authors find that while an experimental symptomless infection of tularemia may be produced in the ring-necked pheasant, the difficulties in establishing the infection indicate that probably this bird would be immune to tularemia under conditions of natural infection.

The germicidal efficiency of chlorine and chlorine compounds, E. C. McCULLOCH (*Vet. Med.*, 28 (1933), No. 3, pp. 92-97, figs. 3).—A practical account of the germicidal value of chlorine and chlorine compounds.

Hexylresorcinol as a general vermicide, P. A. CLAPHAM (*Jour. Helminthol.*, 10 (1932), No. 4, pp. 195-208).—The author concludes that hexylresorcinol is as effective as a vermicide as a bactericide. After referring to the work of Lamson and his associates, who have shown it to be effective in removing some nematodes (*E.S.R.*, 65, p. 568; 67, p. 310), the author reports having obtained similar results with cestodes. Experiments on free-living nematodes and larvae of parasitic nematodes have shown it to be extremely effective. In each case the drug acts as a protoplasmic poison by precipitating the protein contents.

The photodynamic action of methylene blue on certain viruses, J. R. PERDRAU and C. TODD (*Roy. Soc. [London], Proc., Ser. B*, 112 (1933), No. B 777, pp. 288-298).—The authors have found that "the viruses of vaccinia, herpes, fowl plague, louping-ill, Borna disease, Fujinami's tumor, and canine distemper, as they exist in filtrates or other fluids devoid of living cells, are highly sensitive to the photodynamic action of methylene blue—a concentration of 1 part in 100,000 inactivating each of these viruses within a few minutes under suitable illumination. The viruses of foot-and-mouth disease and of infectious ectromella, on the other hand, are more resistant to the photodynamic action of the dye. The inactivation of the viruses by methylene blue and visible light appears to be an oxidative process, as in experiments with the viruses of herpes and vaccinia no inactivation took place in the absence of free oxygen. The viruses of herpes, Borna disease, and fowl plague, as they exist in freshly prepared suspensions of living cells from infected animals, are very much more resistant to the photodynamic action of the dye than they are in cell-free filtrates. This 'protection' of the viruses is only exercised by living cells, dead cells being without effect. No such protection by the living animal cell was observed in the case of the virus of louping-ill, and in that of the virus of vaccinia the amount of protection obtained was very small."

Vaccines and their importance in animal husbandry, J. B. BUXTON (*Husbandry [Norfolk Co. Council]*, 2 (1932), No. 4, pp. 3-7; 3 (1933), No. 1, pp. 3-8).—The first part of this contribution (pp. 3-7) deals with the nature of vaccines and their value to animal husbandry. This is followed in the second part (pp. 3-8) by an account of tuberculosis and the use of the B.C.G. method of immunizing cattle against it.

The American groundsel species of *Senecio* as stock poisoning plants, A. B. CLAWSON (*Vet. Med.*, 28 (1933), No. 3, pp. 105-110, figs. 5).—Feeding experiments with three American species of *Senecio* are reported.

"*S. integerrimus* is shown to be capable of poisoning horses and cattle, but it is pointed out that because of its habits of growth it is not a source of particular danger on the range or in pastures. *S. longilobus* is shown to be one of the more poisonous of the American species of *Senecio* and a source of danger for grazing animals. Data are given regarding its toxicity for cattle, horses, and sheep, and it is pointed out that the young leaves are more poisonous than the older leaves or the stems. *S. spartoides* is added to the list of plants known to be poisonous."

Investigations on the structural changes in the bones of normal cattle and of cattle receiving calcium- and phosphorus-deficient diets [trans. title], A. THEILER (*Denkschr. Schweiz. Naturf. Gesell.*, 68 (1932), No. 1, pp. I+154, pls. 22; rev. in *Jour. Amer. Vet. Med. Assoc.*, 82 (1933), No. 1, pp. 115-117).—The first part of this work (pp. 1-96) deals with the structure and thickness of the cortical portions of the bones of cattle and the second part (pp. 97-154) with experimental rickets and osteomalacia in cattle.

Bovine contagious abortion: The need for further research, H. R. SEDDON (*Agr. Gaz. N. S. Wales*, 43 (1932), No. 11, pp. 821-829).—Reporting upon the status of knowledge of this disease, the author calls attention to the need for more exact information concerning it.

[Contributions on infectious abortion] (*Jour. Amer. Vet. Med. Assoc.*, 82 (1933) No. 3, pp. 309-337).—Contributions on infectious abortion presented at the annual meeting of the United States Live Stock Sanitary Association held at Chicago in 1932 include the following: Control of Bang's Disease under Range or Semi-range Conditions, by W. J. Butler and D. M. Warren (pp. 309-318); Bang's Disease in Relation to Interstate Cattle, by T. E. Munce (pp. 318-327); Some of the Things We Should Recognize concerning the Agglutination Test for Bang's Disease, by C. R. Donham (pp. 327-335); and Report of Committee on Bang's Disease, by C. P. Fitch et al. (pp. 335-337).

Can *Bacillus abortus* Bang penetrate through the normal skin, and is this an important channel of entrance in bovine infectious abortion? [trans. title], O. BANG and H. C. BENDIXEN (*Medlemsbl. Danske Dyrlægefor.*, 15 (1932), No. 1, pp. 1-11; *abs. in Cornell Vet.*, 22 (1932), No. 2, pp. 195-198).—Studies made with a view to determining whether the main portal of entry of *B. abortus* is by way of the alimentary tract or in other ways are reported. Two attempts at infection by bandaging infected material to the shaved skin proved positive in one, and a colony of *B. abortus* was obtained in cultures from the popliteal and mammary lymph nodes although the blood was negative at a dilution of 1:25. A small piece of cotton soaked with positive placental scrapings which was placed on a teat scarified with five to six scratches not deep enough to draw blood, resulted in infecting the placenta and the udder. Infection through the unshaved skin of the pastern resulted from the application of a bandage of infected material to a cow and two heifers.

The application for 4 days of infective material to the right front teat, the skin of which was scarified although no blood exuded, resulted in the infection of the placenta and of the milk.

The occurrence of Johne's disease of cattle in Valtellina [trans. title], E. SIMONATTI and P. BRUNELLI (*Proflassi*, 6 (1933), No. 1, pp. 1-7, figs. 7; *Fr. abs.*, p. 7).—Detailed case reports are given of chronic paratubercular enteritis of cattle, which is recorded from Valtellina, Italy, for the first time.

Studies on the control of Johne's disease, W. A. HAGAN and A. ZEISSIG (*Jour. Amer. Vet. Med. Assoc.*, 82 (1933), No. 3, pp. 391-407).—The authors present data to support the conclusion that "Johne's disease in cattle can be diagnosed with a reasonable degree of accuracy by the aid of avian tuberculin injected intravenously. The dosage of the tuberculin must be carefully graded so as to induce sharp reactions in affected cattle and give none in normal cattle. . . . We have found complement fixation useful as a confirming test, used with the allergic test. It is useful especially in those animals which have developed clinical signs of the disease and do not react to the allergic test, for these animals practically always react serologically."

Mal de caderas of cattle or pasteurellosis paresis of Paraguay [trans. title], R. URÍZAR and V. G. FRACCHIA (*An. Inst. Nac. Parasitol. [Asunción]*, 2 (1929), No. 2, pp. 5-31, figs. 8).—This contribution deals with a disease of cattle, later accounts of which by Migone and Peña and by Urizar have been noted (*E.S.R.*, 68, p. 250).

Pasteurellosis paresis or mal de caderas of cattle [trans. title], R. URÍZAR, V. FRACCHIA, and J. B. RIVABOLA (*An. Inst. Nac. Parasitol. [Asunción]*, 2 (1929), No. 2, pp. 33-68, figs. 2).—This contribution on the disease above noted reports experimental studies of its cause, presented in connection with an 11-page list of references to the literature.

A six-month study of bovine mastitis in herd of 100 cows, F. B. HADLEY and W. D. FROST (*Jour. Amer. Vet. Med. Assoc.*, 82 (1933), No. 3, pp. 345-355).—Contributing from the Wisconsin Experiment Station, the authors report that in a herd of 102 cows examined monthly for a period of 6 months 30 were found to be affected with definite clinical mastitis. It was found that 60 cows in the herd were normal or nearly so, none of these having a total bacterial count above 20,000 per cubic centimeter. In this herd there were 12 cows classed as suspicious cases, which, with the 30 clinical cases, made a total of more than 40 percent having either evident or latent mastitis sometime during the course of the 6 months.

It is concluded that "when a streptococcus becomes implanted in the udder it has a remarkable ability to remain. While the data presented do not warrant making a diagnosis of mastitis on merely demonstrating streptococci in the udder, it does show that clinical symptoms are much more likely to be present in those cows shedding streptococci than in those cows whose milk does not contain them. The etiological agent of mastitis found most frequently in this herd is a member of the alpha hemolytic group of streptococci, known as *S[treptococcus] mitis* according to Holman's system of classification and as *S. agalactiae* by other investigators. Other alpha types were found, viz, *S. faecalis* and *S. salivarius*, in a few cases. A few cases also were caused by members of the colon-aerogenes group."

A biological and bacteriological study of bovine mastitis, J. M. ROSELLI and W. T. MILLER (*Jour. Amer. Vet. Med. Assoc.*, 82 (1933), No. 4, pp. 587-607).—The authors report upon examinations made of samples of milk from each quarter of 70 cows for the presence of mastitis, both bacteriologically and by application of several chemical and biological tests.

Of the 280 quarters tested, 82.8 percent were found to be abnormal by one or more of the various methods used. The type of mastitis appeared to be of a chronic nature, no acute cases having been found.

"The number of quarters, of the 232 found to be diseased, were positive to the individual tests as follows: Chlorine test, 192 (82.7 percent); catalase test, 167 (72.6 percent); bromothymol blue test, 69 (30 percent); macroscopic and microscopic sediment test, 137 (59.5 percent); palpation, 151 (65.6 percent); black cloth test, 15 (6 percent)."

Streptococci were present in 41 percent of the diseased quarters and were present in 21 percent of the 48 quarters which failed to react to any of the tests, although in a second test of the latter many failed to show streptococci. The authors describe a method for applying the chlorine test in the stable, which may be used in connection with the bromothymol blue test.

"Forty-one strains of streptococci isolated during this work were tested. Two strains could be classified as *S[treptococcus] bovis*, one as *S. mitis*, and three as *S. faecalis*. It is believed that the presence of these six strains may possibly be due to outside contamination. The 35 other strains could be classified as *S. agalactiae* (*mastitidis*).

"The *S. agalactiae* (*mastitidis*) strains acidified, coagulated, and partially reduced litmus milk in 48 hours at 37° C., did not change methylene blue milk in 24 hours (several strains caused slight reduction), fermented lactose (pH. 4.4 to 4.6), saccharose, and salicin. They did not act upon mannite, raffinose, or inulin, did not liquefy gelatin, and failed to reduce nitrates to nitrites. They were not hemolytic."

The account is presented in connection with a list of 51 references to the literature.

[Contributions on bovine tuberculosis] (*Jour. Amer. Vet. Med. Assoc.*, 82 (1933), No. 3, pp. 407-414, 420-427, 432-440).—Contributions presented on tuberculosis of livestock at the annual meeting of the United States Live Stock Sanitary Association, held at Chicago from November 30 to December 2, 1932, include the following: The Three Types of Tubercle Bacilli in Live Stock Sanitary Control Work, by L. Van Es; Progress of Cooperative Tuberculosis Eradication Work, by A. E. Wight; and Accrediting Range and Semi-range Cattle as Tuberculosis-Free, by F. E. Mollin.

A detailed study of no-lesion, tuberculin-reacting cattle, E. G. HASTINGS, W. WISNICKY, B. A. BEACH, and J. MCCARTER (*Jour. Amer. Vet. Med. Assoc.*, 82 (1933), No. 4, pp. 565-583).—A detailed study at the Wisconsin Experiment Station of two groups of cattle consisting of one-reactor-per-herd animals indicates that some other organism or organisms than the bovine tubercle bacillus may sensitize cattle to tuberculin. The organisms suspected of being implicated include the avian and the human tubercle bacilli, possibly John's bacillus, and the saprophytic members of the tubercle group of bacteria.

"It is believed that the observations herein recorded indicate that the herd history may, in the final stages of the eradication of bovine tuberculosis, serve as a supplement to the tuberculin test. It may prove possible to avoid the removal of a considerable part of those animals which now form the no-lesion group without endangering the eradication work in any way by allowing herd history to influence the judgment as to the condition of the herd as regards tuberculosis."

A general survey of the protozoan fauna of the rumen of the Chinese cattle, T. S. HSIUNG (*Bul. Fan Mem. Inst. Biol.*, 3 (1932), No. 7, pp. 87-107, pl. 1).—This is a report of a survey made of the protozoan fauna of the rumen of Chinese cattle, based upon examinations of 30 animals. Some species were found to be specific for the host and some commonly found in both cattle and sheep. Of the 66 forms identified, 6 species are described as new, 1 of which represents a new genus, *Pingius*.

The protozoan fauna of the rumen of the Chinese sheep, T. S. HSIUNG (*Bul. Fan Mem. Inst. Biol.*, 2 (1931), No. 3, pp. 29-43, pl. 1).—This is chiefly a preliminary report of a survey of the protozoan fauna of the rumen of sheep slaughtered in an abattoir in Tientsin, China. Forty species of protozoa are here recorded, of which one is described as new. The incidence of the various species is shown in tabular form.

Anthrax protection tests, J. REICHEL and J. E. SCHNEIDER (*Jour. Amer. Vet. Med. Assoc.*, 82 (1933), No. 3, pp. 376-387).—The authors conclude that "it is possible to establish an infective dose for sheep with a virulent anthrax culture of value in the protection test. Such a sheep protection test will reveal the relative protective value of anthrax antigen, anthrax vaccine (southern), and anthrax bacterin. It will also permit of the test for potency of anti-anthrax serum. Anthrax antigen and anthrax vaccine (southern), so tested, increased resistance in the sheep injected 30 days prior to the administration of the infective dose. Anthrax bacterin, as used in the tests, failed to increase the resistance of the sheep. Additional sheep protection tests with the same infective dose should be made with anthrax antigen and anthrax vaccine (southern) to establish further the lasting qualities of the immunity."

"Cripples" in lambs, W. L. STEWART (*Vet. Jour.*, 89 (1933), No. 2, pp. 63-69, pl. 1).—An account is given of a disease of young lambs, occurring on certain farms in the north of England and known as "cripples", "stiffness", and "rickets", which affects moderately well-nourished lambs from the age of

7 to 14 days. The infection is characterized by stiffness of gait and by an abnormal fragility of the long bones and ribs, resulting in their frequent fracture from comparatively simple causes. The crippled lambs are said to show symptoms resembling the so-called stiff lambs reported by H. J. Metzger and W. A. Hagan in New York.⁴

"Cripples" in lambs, W. L. STEWART (*Vet. Rec.*, 13 (1933), No. 6, pp. 109-112).—This contribution relates to the disease of lambs noted above.

"Pulpy kidney" in lambs (*Aust. Council Sci. and Indus. Res. Pam.* 35 (1932), pp. 29).—This consists of two papers as follows: "Pulpy Kidney," or Acute Infectious Entero-toxaemia of Sucking Lambs Due to *B[acillus] oviscapis* (Bennetts), by D. T. Oxer (pp. 9-25) (*E.S.R.*, 67, p. 600), and "Pulpy Kidney", a Post-mortem Change in Experimental Infectious Entero-toxaemia, by H. W. Bennetts (pp. 26-29).

Experiments in the treatment of stomach worms in sheep, F. H. S. ROBERTS (*Queensland Agr. Jour.*, 38 (1932), No. 6, pp. 493-507).—The author finds carbon tetrachloride in a 2 cc adult and 1 cc lamb dose, combined with liquid paraffin to make 5 cc, the most successful method of treatment for the stomach worm *Haemonchus contortus*. Arsenic and Epsom salts and copper sulfate and mustard in the doses used are also highly efficient, with little to choose between them but with the former drench perhaps the cheaper and more efficient. Tetrachlorethylene gave very disappointing results, and in any case its cost as compared with that quoted for carbon tetrachloride, etc., would prohibit its use, the treatment of 1,000 sheep costing a little more than 22s. Further experiments are required with sodium arsenite and copper sulfate and with sodium fluosilicate before any definite opinion on their efficiency against *H. contortus* can be expressed.

Field observations on erysipelas in swine herds, C. F. HARRINGTON (*Jour. Amer. Vet. Med. Assoc.*, 82 (1933), No. 3, pp. 492-503).—The author reports having found swine erysipelas to be a serious hazard to swine production on certain farm premises and in some definite areas. It is pointed out that many farms may become abandoned to hog raising because of the annual destruction of the herd as the result of the recurrence of the disease.

A laboratory tube test and a whole blood rapid agglutination test for the diagnosis of swine erysipelas, W. H. SCHOENING, G. T. CREECH, and C. G. GREY (*North Amer. Vet.*, 13 (1932), No. 12, pp. 19-25, figs. 3).—The authors describe a tube agglutination test and a rapid plate agglutination test using whole blood, perfected for use in the diagnosis of swine erysipelas due to *Erysipelothrix rhusiopathiae*. This disease has been reported from various sections of the United States in recent years as occurring in the acute form.

An agglutination test for swine erysipelas, H. W. SCHOENING and G. T. CREECH (*Jour. Amer. Vet. Med. Assoc.*, 82 (1933), No. 3, pp. 503-508).—A description is given of an agglutination technic developed as noted above. Further experimentation in the laboratory and field studies of the technic reported is required to determine its practical application to the diagnosis of swine erysipelas in the field.

The antigenic properties of bacteriophage lysates of *Salmonella suispestifer*, I. II, P. KENDRICK (*Amer. Jour. Hyg.*, 17 (1933), No. 2, pp. 297-317, pla. 3; 318-328).—The first contribution reports upon a preliminary study made of the cultures and bacteriophage lysates to be used in further experimental work. The second contribution deals with the rate of disappearance of injected bacteriophage from the blood stream of rabbits, experimental data being re-

⁴ Cornell Vet., 17 (1927), No. 1, pp. 35-44, figs. 2.

corded for 21 rabbits relative to the disappearance of *B[acterium] suispestifer* bacteriophage.

Water hemlock (*Cicuta maculata* L.) poisoning in swine, L. V. SKIDMORE (*Vet. Jour.*, 89 (1933), No. 2, pp. 76-80, fig. 1).—In experiments in Nebraska the consumption of nearly 5 lb. of green tops of *C. maculata* did not produce symptoms of poisoning in a hog. Seven days later this animal succumbed in 1 hour 15 minutes after having consumed 275 g of the ground-up roots.

Equine encephalomyelitis antiserum, E. RECORDS and L. R. VAWTER (*Jour. Amer. Vet. Med. Assoc.*, 82 (1933), No. 4, pp. 608-616).—Contributing from the Nevada Experiment Station, the authors present what they consider to be a reasonably practical, proven, and satisfactory method of producing and testing anti-equine encephalomyelitis serum at a moderate cost.

Of seven horses treated substantially in accord with this outline, only one has failed to respond to hyperimmunization satisfactorily. No abscesses, loss of condition, or deaths have occurred in the serum-producing horses which could be attributed to the hyperimmunizing and bleeding process per se. The presence of equine anemia infection in the serum horses or their subsequent infection from horses used for virus production appears to be the biggest hazard in areas where this disease exists. This disease not only renders the infected serum horse useless, but there is apparently grave danger of its dissemination by the finished serum if used shortly after its production. Work not covered in this paper indicates that anti-encephalomyelitis serum has marked value as a therapeutic agent. Given early in an attack, the death rate is lowered, convalescence is shortened, and the percentage of animals showing permanent damage is greatly reduced. Preliminary trials would indicate that its value for immunizing purposes is limited. Any passive immunity conferred appears at best to be slight and short lived.

Studies of horses treated for strongylidosis, E. E. SLATTER, S. E. PARK, and R. GRAHAM (*North Amer. Vet.*, 14 (1933), No. 3, pp. 19-33, figs. 14).—"In a group of 140 U.S. Army horses, 6 died of strongylidosis before treatment was instituted and 5 more animals succumbed from strongyle infestation during the period of treatment. Clinical symptoms of parasitism in other horses of this group were supported by positive fecal examinations. Oil of chenopodium and carbon tetrachloride were administered for *Strongylus* spp. infestation. The treatment of horses, with relatively few exceptions, was followed by noticeable improvement. In a group of 21 clinical cases subjected to repeated treatment, general improvement was correlated with increased body weight and undulating but rising hemoglobin content of the blood. Badly infested animals responded slowly, but gradually improved in general appearance and ability to work. The increase in body weight during the period of 6 months doubtless was influenced favorably by the rations and rest during the summer months of 1932."

Canine coccidiosis due to *Elmeria canis*, L. V. SKIDMORE and C. B. McGEATH (*Jour. Amer. Vet. Med. Assoc.*, 82 (1933), No. 4, pp. 627-629).—The authors report on a case of coccidiosis in the dog at Lincoln, Nebr., which they believe to be due to *E. canis*, as described by C. M. Wenyon¹ in 1923 and O. Nieschulz² in 1924.

Laboratory and clinical diagnosis of canine distemper, M. L. MORRIS (*North Amer. Vet.*, 14 (1933), No. 3, pp. 34-48, figs. 6).—The author finds that by a study of the blood picture it is possible to detect canine distemper in the

¹ Ann. Trop. Med. and Parasitol., 17 (1923), No. 2, pp. 231-288, pls. 6, figs. 2; abs. in Jour. Amer. Vet. Med. Assoc., 65 (1924), No. 4, pp. 496, 497.

² Berlin. Tierärztl. Wchnschr., 40 (1924), No. 17, pp. 220, 221, figs. 2.

incubation stage by the rise in white blood count and the lowered nuclear index. The nuclear index, or relation between the immature and the mature polymorphonuclear leucocytes, was found to be a dependable index in following the progress of the virus of canine distemper and the associated organisms.

The effect of blood loss upon the resistance of chickens to variable degrees of parasitism, D. A. PORTER and J. E. ACKERT (*Amer. Jour. Hyg.*, 17 (1933), No. 1, pp. 252-261, fig. 1).—In this contribution from the Kansas Experiment Station the authors report upon two experiments on a total of 300 White Leghorn chickens, conducted with a view to determining whether the resistance of chickens to variable degrees of parasitism with the intestinal nematode *Ascaridia lineata* (Schneid.) is affected by periodic blood losses.

"The results of the experiments indicate that repeated loss of blood may lower the resistance of chickens to the intestinal nematode *A. lineata*. When large numbers (500 or 300) of eggs were fed, three of the four lots bled showed significantly longer worms than did the control lots of chickens (not bled). While several comparisons did not result in significant differences (due to variability), the worms from the bled lots of chickens were longer than those from the controls in nine of the ten groups in which comparisons were made. The lowered resistance is thought to have been due to a physiological reaction in which the growth-inhibiting mechanism was affected."

A direct method for making total white blood counts on avian blood, D. BLAIN (*Soc. Expt. Biol. and Med. Proc.*, 25 (1928), No. 7, pp. 594-596).—Having found the methods employed with mammalian blood unsatisfactory in making total leucocyte counts of avian blood, the author has devised the method here described.

The character and extent of poultry diseases as evidenced by data obtained in Government inspection work, L. D. IVES (*Jour. Amer. Vet. Med. Assoc.*, 82 (1933), No. 3, pp. 480-486).—A report on the diseases observed in the course of inspection of all live poultry unloaded for sale in New York City and on the inspection of the dressed poultry used in canning plants putting up poultry food products or in plants preparing full-drawn poultry for sale.

[Work with diseases of poultry in Rhode Island] (*Rhode Island Sta. Rpt.* [1932], pp. 57-59).—The work of the year with diseases of poultry briefly referred to (E.S.R., 67, p. 318) includes coccidiosis, blackhead, fowl pox, and an unrecognized respiratory infection in chickens and pheasants.

The control of poultry coccidiosis by the chemical treatment of litter, J. ANDREWS (*Amer. Jour. Hyg.*, 17 (1933), No. 2, pp. 466-490, pl. 1, figs. 4).—The author has found in the experimental work reported that Toxite, a proprietary disinfectant the base of which appears to be a mixture of the higher phenoloids, including in all probability cresylic and xylenylic fractions, when sprayed on litter once each week controlled mixed poultry coccidiosis under conditions of poor sanitation (cleaning at least once in three weeks) and deliberate contamination.

"In the continued absence of cleaning, Toxite did not protect flocks against coccidial epidemics indefinitely. Its coccidiacidal activity was apparently limited by the accumulation of organic matter in the litter. Half-strength Toxite applied twice each week in the absence of cleaning postponed the normal development of coccidial epidemics, but not for as long a time as full-strength Toxite applied once each week. A water-borne mixture of Toxite base of the same chemical strength as regular Toxite applied each week in the absence of cleaning failed to postpone the normal development of a coccidial epidemic. Evidence has been adduced which shows that Toxite was more active against freshly passed oocysts than against infective oocysts."

Poultry coccidiosis control by the chemical treatment of litter, J. ANDREWS (*Poultry Sci.*, 12 (1933), No. 2, pp. 133-140, figs. 2).—In experimental work with a chemical spray consisting of a mixture of coal-tar acids in a light mineral oil, its application on a litter once each week controlled avian coccidiosis of various types under conditions of poor sanitation and deliberate contamination, as above noted. "In the absence of cleaning, Toxite protected a flock against coccidiosis for 4 weeks but not for 5. Regular weekly application of Toxite, supplemented by cleaning and removal of litter at least every 3 weeks, is recommended to control coccidiosis successfully. A water-borne mixture of Toxite base of the same chemical strength as Toxite had apparently no value in controlling coccidiosis."

Etiology of an uncomplicated coryza in the domestic fowl, J. B. NELSON (*Soc. Expt. Biol. and Med. Proc.*, 30 (1932), No. 3, pp. 306, 307).—In the author's investigation "an uncomplicated coryza was initiated and subsequently maintained in a flock of disease-free birds by the intranasal injection, through the palatine cleft, of exudate originally obtained from naturally infected fowl. A nasal discharge, the only consistent symptom, generally appeared after an incubation period of 24 to 28 hours and continued, on the average, for 11 days.

"The etiological agent of the coryza was not established by the injection either of bacteria isolated from aerobic plates or of exudate filtered through Berkefeld V and N candles. . . . It was subsequently found, however, that the fluid from blood agar cultures of exudate which had been filtered through certain Berkefeld V candles contained a small, nonmotile, Gram-negative bacillus apparently in a pure state. The organism grew sparsely in fluid blood at the base of slanted agar but failed to colonize on the slant or on the surface of aerobic blood agar plates. Colonization was later initiated by sealing the plates with modeling clay.

"A typical coryza was produced in normal birds, 35 in all, by injecting the bacillus into the palatine cleft. The same organism was recovered from the nasal exudate induced in these birds, at first by filtration and later by the use of sealed plates. The duration of the period of nasal discharge, averaging 5 days, was shorter than that of the coryza produced by exudate. There was also an indication that the bacillary coryza was less communicable by direct contact. . . . It was found that recovery from the coryza of bacillary origin was commonly followed by a state of resistance to reinfection."

While cultural studies are not complete, the failure of the organism to colonize on aerobic blood agar plates, together with an inability to multiply in media containing sufficient accessory material of plant origin to support growth of *B[acillus] influenzae*, appears to exclude it from the group of true hemophilic bacteria.

Observations on the use of pigeon-pox virus as a cutaneous vaccine for fowl-pox in an egg-laying contest, F. H. ORR, JR., and M. W. EMMEL (*Jour. Amer. Vet. Med. Assoc.*, 82 (1933), No. 4, pp. 562-564).—The authors report that the use of pigeon pox virus as a cutaneous vaccine for fowl pox proved most satisfactory to the management of the Alabama egg-laying 1931-32 contest, the results seeming to warrant its use in future contests in the State.

Experiments on immunization against laryngotracheitis in fowls, F. R. BEAUDETTE and C. B. HUDSON (*Jour. Amer. Vet. Med. Assoc.*, 82 (1933), No. 3, pp. 460-476).—Contributing from the New Jersey Experiment Stations, the authors point out that swabbing of the cloacal mucosa or that of the bursa of Fabricius with a virus suspension results in an infection of these parts (E.S.R., 67, p. 747). The disease process runs its course in about 1 week, after which

the cloaca, as well as the respiratory tract, is immunized against it. It is thought that successful infection of the cloaca probably depends upon the dose of virus.

"It is important to induce cloacal infection in every bird, otherwise the ones not so infected are exposed to the infection eliminated by those successfully vaccinated. If cloacal infection is induced in every bird there is no loss attending immunization, otherwise the losses are almost entirely confined to the birds in which cloacal infection was not successful. In any event the loss has never been unusual. Vaccination of young chicks was not satisfactory, and in birds 6 months old the percentage of takes was not large enough, although a larger dose of virus may compensate to some extent. The most desirable age for vaccination seems to be between 2 and 3 months. Infection of the cloaca may be facilitated by rotating the swab on the mucosa or by the addition of an inert abrasive substance. Limited observations seem to indicate that vaccinated birds do not continue to carry the virus in the cloaca."

Leucosis of the fowl, a diagnostic study, H. HEINSEN (*Leukose der Hühner, eine Diagnostische Studie. Inaug. Diss., Hyg. Inst. Tierärztl. Hochsch., Hannover, 1930, pp. 68*).—An investigation of 20 fowls suffering from leucosis showed 25 percent to be affected with the myeloid type, 70 percent with the lymphatic type, and 5 percent with the myelolymphatic type. The report is presented in connection with a list of 65 references to the literature.

Report of the conference of official research workers in animal diseases of North America on standard methods of pullorum disease in barnyard fowl, November 29, 1932 (*Jour. Amer. Vet. Med. Assoc., 82 (1933), No. 3, pp. 487-491*).—This report deals with (1) the diagnosis of the disease in young chicks and (2) with serological diagnosis of pullorum disease (carrier condition) in maturing and in adult breeding stock.

A study of pullorum disease diagnostic tests, R. GRAHAM, F. THORP, JR., and J. P. TORREY (*Poultry Sci., 12 (1933), No. 2, pp. 112-119*).—"Comparisons of the results of the pullorin or intradermal, the rapid plate, the rapid whole blood stained antigen, and the field tube tests with the standard tube test showed a lower correlation between positives than between negatives, or conversely, a higher agreement between negatives than between positives. Using the standard tube test as an arbitrary standard of perfection, the pullorin test agreed in 72 to 91 percent of the fowls tested; the rapid plate test agreed in 72 to 96 percent; the rapid whole blood antigen in 72 to 90 percent; and the field tube test agreed in 81 to 95 percent."

Newly recognized poultry disease, F. R. BEAUDETTE and C. B. HUDSON (*North Amer. Vet., 14 (1933), No. 3, pp. 50-54*).—This contribution from the New Jersey Experiment Stations presents 11 case reports of an apparently new disease, first met with in August 1932 in Hunterdon County, N.J. The disease is characterized by a swelling of the periorbital tissues, which may extend over the face and frequently involves the wattles and submaxillary space. The swollen wattle is frequently cyanotic, and the swelling occasionally involves the top of the head. The swellings appear and disappear in a relatively short time. Sneezing and mild respiratory symptoms are frequently seen, but on autopsy one does not find the exudate peculiar to infectious laryngotracheitis.

Some observations on the development of the caecal worm, *Heterakis gallinae* (Gmelin, 1790) Freeborn, 1923, in the domestic fowl, A. D. BAKER (*Sci. Agr., 13 (1933), No. 6, pp. 356-363, figs. 8*).—It is pointed out that the reports of studies which have been made of the development of *H. papillosa* in all probability refer to *H. gallinae*.

In reviewing the literature the author has found that there is no general agreement as to the length of time required for the cecal worm to complete its development within the chicken, records ranging from 24 to 61 days. The author has found that the development of *H. gallinae* in the chicken is frequently completed within a 30-day period. "Blackhead frequently makes its appearance in chickens by the second and third weeks after ingestion of embryonated cecal worm egg material. Cecal worms recovered from chickens badly infested with blackhead have been observed as being markedly checked in their development. It appears evident that excessive development of blackhead in the ceca of chickens tends to render conditions rather unsuitable for the development of *H. gallinae*."

It is thought that the influence of blackhead is sufficient to explain the difference in the findings of those that have studied the life cycle of the cecal worm.

On the life-history of *Heterakis gallinae*, P. A. CLAPHAM (*Jour. Helminthol.*, 11 (1933), No. 2, pp. 67-86, figs. 16).—This is a report of studies of the fowl nematode *H. gallinae*, better known as *H. papillosa*, presented in connection with a list of 24 references to the literature.

The life history of *Leucocytozoon anatis* Wickware, E. C. O'ROKE (*Jour. Parasitol.*, 18 (1931), No. 2, p. 127).—An account is given of a parasitic protozoan, *L. anatis*, which infests both wild and domestic ducks, in which it causes serious juvenile losses. Gametocytes which are present in the red blood cells are ingested by the female of the blood-sucking black fly *Simulium venustum*.

The blackfly, *Simulium venustum* Say, and a protozoan disease of ducks, C. R. TWINN (*Canad. Ent.*, 65 (1933), No. 1, pp. 1-3).—The author reviews recent literature on the disease of ducks due to *Leucocytozoon anatis* and common in Canada, which was first reported by Wickware at Ottawa in 1915 (*E.S.R.*, 33, p. 488) and by O'Roke in 1930 as transmitted by *S. venustum* (*E.S.R.*, 64, p. 565). The author then considers the possible role of this black fly in its dissemination, and records are given of its occurrence in the several Provinces of Canada.

Endemic paratyphoid infection in turkeys, L. F. RETTGER (*Jour. Amer. Vet. Med. Assoc.*, 82 (1933), No. 3, pp. 452-460).—This general account of paratyphoid infection in turkeys contributed from the Connecticut Storrs Experiment Station includes a history of recurring epizootics on two farms situated 90 miles apart, supplemented by general remarks on blackhead.

AGRICULTURAL ENGINEERING

[Agricultural engineering investigations at the Everglades Substation] (*Florida Sta. Rpt. 1932*, pp. 164-167, 196-198, figs. 2).—The progress results of studies of water control in soils being conducted by R. V. Allison et al. in cooperation with the U.S.D.A. Bureau of Agricultural Engineering are briefly reported.

[Agricultural engineering investigations at the Kansas Station] (*Kansas Sta. Bien. Rpt. 1931-32*, pp. 45-47, 119, 120).—The progress results are reported of studies on the influence of method of harvesting and baling alfalfa hay on quality and on the efficiency of the combined harvester-thresher for harvesting grain sorghums, by F. J. Zink; the effect of the method of storing combined wheat upon quality, by F. C. Fenton and C. O. Swanson; and soil erosion and moisture conservation.

Surface water supply of the United States, 1931, Parts 3, 6, 12A, 12C (*U.S. Geol. Survey, Water-Supply Papers 713* (1933), pp. IX+346, fig. 1; 716 (1933), pp. X+347, fig. 1; 722 (1933), pp. VIII+188, fig. 1; 724 (1933), pp. VI+

166, *fig. 1*).—Part 3 of this report, prepared in cooperation with the States of Illinois, Indiana, Kentucky, New York, North Carolina, Ohio, Tennessee, Virginia, and West Virginia, presents the measurements of flow made on streams in the Ohio River Basin during the year ended September 30, 1931. Part 6, prepared in cooperation with the States of Kansas, Missouri, Montana, Nebraska, North Dakota, and Wyoming, part 12 A, prepared in cooperation with the States of Idaho, Montana, and Washington, and part 12 C, prepared in cooperation with the States of Oregon and Washington, present corresponding measurements for the Missouri River Basin and the North Pacific slope drainage basins (part 12 A dealing with the Pacific slope basins in Washington and the upper Columbia River Basin and part 12 C with the Pacific slope basins in Oregon and lower Columbia River Basin), respectively.

Surface water supply of Hawaii, July 1, 1930, to June 30, 1931 (*U.S. Geol. Survey, Water-Supply Paper 725 (1933), pp. IV+99*).—This report, prepared in cooperation with the Territory of Hawaii, presents the measurements of flow made on certain streams and ditches in the Territory during the year ended June 30, 1931.

Daily river stages at river gage stations on the principal rivers of the United States, compiled by M. W. HAYES (*U.S. Dept. Agr., Weather Bur., Daily River Stages, 29 (1931), pp. III+165*).—This volume, containing the daily river stages for 1931, is the twenty-ninth of a series on the principal rivers of the United States (*E.S.R., 66, p. 472*).

[**Irrigation investigations at the New Mexico Station**] (*New Mexico Sta. Rpt. 1932, pp. 73-80*).—The progress results are reported of investigations on duty of water for cabbage, rate and cause of rise of ground water in the Mesilla Valley, potato culture under irrigation, water requirements and the economical use of water for cotton, rainfall supplemented by underground water in the production of crops of low water requirements, and the effect of fertilizers and frequency of irrigation on the yield and the keeping and marketing qualities of the Early Grano onion. These investigations are being conducted in cooperation with the U.S.D.A. Bureau of Agricultural Engineering.

The physical properties of soil of interest to agricultural engineers, L. D. BAYER (*Agr. Engin., 13 (1932), No. 12, pp. 324-327, figs. 6*).—This contribution from the Missouri Experiment Station briefly discusses those physical factors of soils which are of vital interest to agricultural engineers.

The conclusion is drawn that the moisture content at which tillage is most efficient is dependent upon the consistency of the soil. It is characterized by the moisture content of the soft, friable consistency. Mechanical manipulation causes only a temporary formation of a certain structural condition. Frequency of manipulation is determined by the need for the restoration of this condition of structure.

The conservation of moisture by cultivation is associated with the control of weeds, with the maintenance of such structural qualities of the soil as enhance water absorption, and to some extent with the hindering of evaporation because of the formation of a dust mulch.

Drainage problems are closely related to the structural relationships in soils. The effectiveness of subsurface drainage is wholly dependent upon the degree of aggregation and the noncapillary porosity of the soil profile. The permeability of a soil is determined by the rate of percolation through its least permeable horizon or layer. The depth of the heavy subsoil layer determines the effectiveness of tile drainage in most upland soils. The porosity of the soil also determines the effectiveness of supplementary lateral ditches in the drainage of lowland soils.

A comparison of methods of mechanical analysis of soils, A. CARNES and H. D. SEXTON (*Agr. Engin.*, 14 (1933), No. 1, p. 15).—Studies conducted at the Alabama Experiment Station on methods of mechanical analysis of soils with reference to their utility in connection with soil dynamics studies are briefly reported.

The pipette methods of analysis of soils investigated were found to consume too much time where a great number of analyses were to be made. The same was true with the elutriation method. The Bouyoucos hydrometer method was found to be rapid and sufficiently accurate for work in soil dynamics and erosion studies.

Principles of reinforced concrete construction, F. E. TURNEAURE and E. R. MAUREE (*New York: John Wiley & Sons; London: Chapman & Hall, 1932, 4. ed., rev., pp. XI+461, figs. 220*).—This is the fourth revised edition of this book (E.S.R., 42, p. 589), in which due consideration is given to the latest experiments and developments in methods of calculation and design. Some of the more important changes include revised formulas and diagrams for the design of beams, including circular sections subjected to bending and compression; adaptation of diagrams to the use of any desired value of n ; discussion of recent tests on beams and columns; amplification of material on flat slabs, including detailed treatment of footings; more adequate development of the analysis of continuous beams; application of the slope-deflection method to building frames, including haunched beams, with general results for typical cases; application of method of moment distribution to continuous girders and frames; complete detailed analysis of the arch with methods of arriving at tentative designs; torsional stresses in beams; and effect of shrinkage and plastic flow on stresses in beams, columns, and arches.

Shear tests of reinforced brick masonry beams, D. E. PARSONS, A. H. STANG, and J. W. MCBUNEY ([*U.S.*] *Bur. Standards Jour. Res.* 9 (1932), No. 6, pp. 749-768, figs. 7).—Eighteen beams of reinforced brick masonry were tested to determine their resistance to failure by diagonal tension. The beams were 14 ft. long and about 1 ft. square in cross section. Beams of three different types of construction were tested, an equal number with each of two kinds of brick. A 1:3 portland cement mortar, with addition of lime equal to 15 percent of the volume of the cement, was used in all beams. Each beam contained six 0.5-in. square steel bars as tensile reinforcement. Tensile and shear tests of the bond between mortar and brick and pull-out tests of steel bars embedded in brick masonry were made to supplement the data from the beam tests.

Positions of the neutral axes in the beams varied with the kind of brick, arrangement of bricks in the beams, and loads. The ratio of depth to neutral axis to depth of the tensile reinforcement increased with an increase in the number and total thickness of mortar joints in the masonry. The position of the neutral axis corresponded to that calculated by means of the design formulas applying to beams of reinforced concrete, with an assumed modulus of elasticity of the masonry equal to from 50 to 70 percent of that of the masonry piers.

The failures of all beams were accompanied by cracks near the ends of the beams, between a support, and the nearer load. The cracks were evidence of failures by diagonal tension.

Maximum shearing stresses for the different types of beams ranged from 65 to 159 lb. per square inch. Resistance to diagonal tension increased with an increase in the proportion of bricks laid with staggered joints. Shearing strengths of the beams were in the same order as shearing and tensile bond strengths of small masonry specimens.

With the relatively absorbent bricks used, tensile and shearing strengths of the masonry were much greater when bricks were wetted before laying than when laid dry.

Bond strengths as determined by pull-out tests of 0.5-in. square deformed bars embedded about 8 in. in brick masonry ranged from 870 to 950 lb. per square inch. Differences in the kinds of brick and curing conditions did not cause significant changes in bond strength.

Spreading of liquids on solid surfaces: The anomalous behavior of fatty oils and fatty acids, with experiments leading to a tentative explanation, R. BULKLEY and G. H. S. SNYDER (*Jour. Amer. Chem. Soc.*, 55 (1933), No. 1, pp. 194-208, figs. 8).—Several lines of experimental evidence are described in support of the view that the interfacial tension between metals and petroleum oils is substantially greater than between metals and fatty oils or between metals and fatty acids. The energy requirements for spreading on solids being the same as for spreading on liquids, the fatty oils and fatty acids should spread more readily than mineral oils on metal surfaces. Experimentally, fatty oils and fatty acids spread little or not at all while mineral oils spread apparently without limit. The nonspreading of the fatty liquids must therefore be regarded as anomalous.

The higher fatty acids do not wet polished metal surfaces in the ordinary sense, but roll about freely. They deposit an adsorbed film on the surface which reduces the surface energy to a low value. Thin layers of mineral oil containing fatty acids rupture spontaneously on metal surfaces. The explanation is the same as when a similar phenomenon occurs on water, namely, the formation of an underlying film of low surface energy. Thin layers are unstable on areas of low surface energy. Fatty oils and fatty acids are prevented from spreading on metal surfaces by the great reduction in the surface energy of the metal which is brought about to some distance in advance of the spreading layer by the breaking away of an expanding ring or by the condensation of vapors.

Public Roads, [March-April 1933] (*U.S. Dept. Agr., Public Roads*, 14 (1933), Nos. 1, pp. 20+[2], figs. 6; 2, pp. 21-36+[2], figs. 2).—These numbers of this periodical report the current status of Federal-aid road construction as of January 31 and February 28, 1933, respectively. No. 1 also contains an article entitled Tar Surface Treatment of Low Cost Roads (pp. 1-20), and No. 2 an article entitled The Wisconsin Financial Survey (pp. 21-36).

Certain errors of temperature measurement, L. M. K. BOELTER (*Agr. Engin.*, 14 (1933), No. 1, pp. 16-23, figs. 3).—In a contribution from the University of California, data and other technical information are presented on the measurement of ordinary temperatures by means of mercury thermometers, long distance indicating thermometers, resistance thermometers, and thermocouples, special attention being given to the common corrections and precautions necessary to attain an accuracy of $\pm 0.5^\circ$ F.

Piston temperatures in a solid-injection oil engine, G. F. MUCKLOW (*Engineering [London]*, 134 (1932), No. 3493, pp. 745-747, figs. 8).—Studies conducted at the University of Manchester are reported, the object of which was to determine the temperature of the piston of a solid-injection heavy-oil engine at a number of points distributed over the crown and walls and under a variety of running conditions.

With reference to piston temperatures at different loads, the highest temperature was reached at a point in the middle of the central knob of the piston, increasing about 50 percent from less than half load to full load. The temperatures at other points in the central knob were also very high. At points on the edge of the crown the temperature was considerably below that of the

central knob. The temperatures recorded at points below the first set of rings and in the piston skirt showed but little variation with changes of load. At points on the thrust slipper of the piston the temperature was in each case slightly below that of the corresponding point in the upper slipper.

As the jacket outlet temperature was raised, the temperature at points on the central knob decreased. At points close to the edge of the crown the temperature remained very nearly unchanged. The temperatures at points in the piston skirt increased with increase in jacket outlet temperature, the rise being appreciably greater for points situated in the upper side of the piston skirt.

Removal of the diaphragm plate caused a slight fall in piston temperature, the cooling effect increasing with increase of load. The decrease in temperature was greatest at points situated in the piston knob.

The ignition and combustion process in the coal dust engine, W. WENTZEL, trans. by K. GOGGIN (*Forsch. Geb. Ingenieurw., Forschungsheft 343 (1931)*, pp. [4]+23, figs. 21; trans. in *Fuel*, 11 (1932), Nos. 5, pp. 177-196, figs. 19; 6, pp. 222-228, figs. 2).—An experimental apparatus is described for determining the time required for ignition and combustion of coal dust which is injected by means of compressed air into compressed heated air. With this apparatus the effects of temperature and density of the combustion air, injection pressure, particle size, and kind of coal on the ignition lag and combustion time were investigated.

The ignition lag was found to be independent of excess air and almost independent of injection pressure. It increased with decreasing temperature of the combustion air. The ignition limit was reached at a definite temperature, and the ignition lag and the position of the ignition limit were found to depend on the density of the combustion air. The size of the smallest particles present determined the ignition lag, and if no very fine particles were present in the dust the ignition lag increased rapidly. The richer the coal in gas the lower was the ignition limit. For temperatures of combustion air near the ignition limit, the values for ignition lag in the case of prepared dust lay between 0.01 and 0.03 second.

Combustion time was found to be independent of the temperature of the combustion air so long as this was not too near the ignition limit. On the other hand there was a strong dependency on excess air and on injection pressure. The density of the combustion air had no effect on combustion. Combustion time was also greatly dependent on the grain size composition of the dust. With sufficient excess air and good injection the values for combustion time of prepared dust lay between 0.15 and 0.35 second, according to the grain size composition and kind of coal. These results are discussed in their application to the operation of the coal dust engine.

V-belt drives for farm motors and equipment, H. BERESFORD (*Idaho Sta. Circ. 70 (1932)*, pp. 14, figs. 11).—This circular reports one of a series of studies conducted by the station in cooperation with the Idaho Committee on the Relation of Electricity to Agriculture.

It has been found that V-belt drives for farm motors and equipment are efficient, flexible, and well adapted to most belt-driven farm machinery suited to electric motor power. High reduction or increased ratio drives are obtained with V-belts at a minimum expense and economy of space. The power transmission capacity of a multiple V-belt drive may be increased by addition of individual belts or strands. Combination V-grooved drives and flat-driven pulleys on portable farm motors and farm machines permit a convenient and satisfactory drive for reduced speed ratio needed on silage cutters, hay choppers, and similar machines. V-belts are not adapted to operation under temperatures above 120° F., or where oil or grease is prevalent.

Tractor and horse power in the wheat area of South Dakota. C. M. HAMFSON and P. CHRISTOPHERSEN (*South Dakota Sta. Circ. 6 (1932), pp. 39*).—The data discussed in this circular, obtained in cooperation with the U.S.D.A. Bureau of Agricultural Economics, indicate that many farms in the wheat area of South Dakota are not operating their separate power units at their maximum efficiency. The low efficiency units are represented by the tractors which consume more fuel and oil per 10 hours than the averages, by the horses which are fed more than the average of other horses doing a similar amount of work, and by tractors and horses that perform less work per 10 hours than the most common performances. Even the averages are not to be considered the optimum of efficiency, since many teams and tractors do better than the averages, and since the averages include power units which were operated with less than their respective optimum loads.

The efficiency of tractors may be improved and the cash costs of operation reduced by making needed repairs and adjustments, by using proper hitches, by operating with an optimum load, and by good bargaining for fuel and oil. Efficiency of horses may be increased and the costs reduced by having harness and implements in best adjustment, by using proper hitches and loads, by economical feeding, and by using mostly young horses. Farm power costs may be further reduced by less threshing of feed crops and by harvesting more of the feed crops with livestock.

Many farms in the South Dakota wheat area do not have the best possible power combinations. Adjustments to secure such combinations frequently involve considerable changes in amounts of land, labor, and capital, and a period of several years. Increasing the crop acreage of farms would reduce the total costs per acre of the power units thereon, and on many farms the increase would make the power units more effective. If the added acreage could be secured with small cash outlay, the net returns to the farm might be enhanced also. A partial shift from the use of a large tractor to more use of a smaller one or a shift from tractor as major power to horses as major power would be desirable on some farms during periods of low prices for farm products. Net returns to the farm business over a period of years should determine any adjustments which would be effective for a long time. Under normal economic conditions net returns are of greater importance than the temporary lowering of cost per unit of power, per unit of land, per laborer, or per unit of product.

Information is also given on adjustment and utilization of farm power under conditions similar to 1932.

Comments on depreciation and repairs of combine harvesters and tractors on the Canadian prairies. E. G. GREST (*Sci. Agr., 13 (1932), No. 1, pp. 26-35*).—An attempt is made in this brief contribution from the Canadian Department of Agriculture to develop a satisfactory method for the calculation of depreciation on combines and tractors in western Canada under average prevailing conditions of operation.

A note on the machines used in the testing of paddy for breakage in milling. A. HAYES (*Agr. and Livestock in India, 2 (1932), No. 2, pp. 162-169, pls. 2, figs. 8*).—Four machines are described and illustrated, including a seed mixer, a huller, a separator, and a rice pounder.

A new type of cotton sorter. E. H. PRESSLEY (*Jour. Amer. Soc. Agron., 25 (1933), No. 2, pp. 89-98, figs. 4*).—A new device upon which combed samples of unginned cotton may be sorted, developed at the University of Arizona, is described and illustrated with remarks on preparation of samples for sorting, some of the results obtained with the sorter, and its advantages.

Artificial drying of hay in Russia [trans. title], M. EVREINOV (*Elektrif. Sel'sk. Khoz.*, 1 (1931), No. 7, pp. 30-44, figs. 19).—The results of experiments on the artificial drying of hay by hot air blast through open stacks or stacks inclosed in tubes are reported. The hot air blast is gravity cleaned and has a temperature of from 90° to 100° C. The data are mostly of a service character but indicate the probability that the process is sound and economical.

Heating the soil by electricity [trans. title], A. TSEKULINA (*Elektrif. Sel'sk. Khoz.*, 1 (1931), No. 7, pp. 46-51, figs. 8).—The methods and equipment used in the electrical heating of soil under 2,200 coldframes for the germination of cotton plants are described and illustrated. The electrical current was conducted through a set of iron wires 12 to 15 cm below the soil which was supported on a wooden grill. Data on installation and operation are given, it being pointed out that the open iron wires are a source of danger.

Electrification of the poultry industry [trans. title], G. SHEKHALEVICH (*Elektrif. Sel'sk. Khoz.*, 1 (1931), No. 7, pp. 52-57, figs. 4).—Data are presented on the installation of electric light in poultry and brooder houses, on the use of ultraviolet ray treatment of poultry, electrical ventilation of poultry houses, electrical incubation, and electrical heating.

The development and use of roofing nails, A. J. DENISTON, JR. (*Agr. Engin.*, 14 (1933), No. 1, pp. 9, 10, fig. 1).—A brief description is given of different types of roofing nails together with recommended practice as to their use.

Deterioration of domestic chimneys, I, II, J. E. MACONACHIE (*Canad. Chem. and Metall.*, 16 (1932), Nos. 11, pp. 270-274, figs. 5; 12, pp. 292-295, figs. 4).—Studies conducted for 2 years at the Ontario Research Foundation are reported, in which special attention was given to the influence of flue gas condensation on chimney deterioration and the development of preventive measures.

A field survey of several cases of chimney deterioration and an analytical study of some of the products pointed to sulfuric and sulfurous acids arising from the condensation of some of the products of combustion as the chief causes of trouble.

Determinations of chimney temperatures and dew points indicated that in order to prevent deterioration, turbulence in the flue gas stream should be avoided. An acid-resistant coating could be successful, and would, in contrast to metallic linings, entail little installation expense. A search for a suitable material resulted in the selection of an asphalt and chromate emulsion that proved to be particularly well adapted to the purpose.

An appendix lists materials tested for protective coating purposes.

The septic tank, E. R. GROSS (*New Jersey Stat. Circ.* 267 (1933), pp. 4, figs. 3).—Practical information is given on the planning and construction of small sewage disposal systems for isolated residences. These include treatment by septic tank and tile absorption area.

AGRICULTURAL ECONOMICS

[Investigations in agricultural economics at the Kansas Station, 1930-1932] (*Kansas Sta. Bion. Rpt.* 1931-32, pp. 19-25).—Findings are briefly given regarding the estimated cost with different yields per acre of producing wheat in 1930 and 1931, farm grain storage facilities in the State, local elevator costs and business required for profitable operation, cooperative marketing by large-scale wheat producers, the seasonal fluctuations of the prices of wheat and the factors affecting such fluctuations, the movement of banking business from the strictly rural sections to the larger cities and from small to large

banks, the methods used by insurance, mortgage and loan, and trust companies in extending long-time credit to agriculture, the distribution of the poultry industry in the State, the relation of size of flocks to egg production and receipts, some factors affecting prices received for eggs, the decline in associations marketing livestock, the time at which and places where Kansas livestock and livestock products are marketed, and the factors influencing the time and place, and the present status of and marketing methods and practices, price-making factors, sources and character of competition, and seasonal variations in production in the fruit and vegetable industry of the State.

Current Farm Economics, Oklahoma, [February and April 1933] (*Oklahoma Sta., Cur. Farm Econ.*, 6 (1933), Nos. 1, pp. 20, figs. 4; 2, pp. 21-52, figs. 5).—Included in the first of these numbers are articles on the general agricultural situation and the foreign trade of the United States in relation to agriculture, by L. S. Ellis; the dairy and wheat situation, by P. H. Stephens; the receipts of sheep at the Oklahoma City markets, 1923-32, and the sheep and lamb situation, by R. A. Ballinger; the beef cattle and hog situation, by P. Nelson; and the potato outlook, by W. J. Green. Tables show (1) by years 1910-32 and for January 1932 and 1933, the indexes of farm prices in Oklahoma and the United States, of prices paid by farmers in the United States, wholesale prices in the United States, the Oklahoma corn-hog ratio, and demand deposits in Oklahoma; and (2) by years 1910-32 and months January 1932 to January 1933, the prices of different Oklahoma farm products, and the index of farm prices of such products and of the purchasing power of all crops, all livestock, and all products.

The April issue includes discussions of the general agricultural situation, by L. S. Ellis; of a long-time view of the competitive position of Oklahoma cotton producers, by J. T. Sanders; of the cattle and hog situation, by P. Nelson; of the wool and broomcorn situation, by R. A. Ballinger; of the economic consequences of the World War debts, by Z. B. Wallin; of the monetary reform in relation to farm relief, by P. H. Stephens; and of some immediate social problems facing Oklahoma agriculture, by O. D. Duncan.

[Investigations in agricultural economics at the Rhode Island Station, 1932] (*Rhode Island Sta. Rpt.* [1932], pp. 41-43).—Some results of studies are given showing (1) the relative average sales price, cost of grading, and net prices received for sized, graded, and labeled and for farmers' pack hothouse tomatoes in 1930 and 1931; (2) comparisons for 1928 and 1932 of the sources and size of purchases of eggs, kinds of eggs purchased, and type of container preferred in the same sections of Providence; and (3) the average costs for feed, labor, overhead, replacements, etc., and the credits in producing milk on 73 Rhode Island farms during February to April 1932.

Agricultural economics, C. S. ORWIN (In *Agricultural Research in 1930*. London: Roy. Agr. Soc. England, 1931, pp. 60-80).—Short summaries are given of the research work in England during the year 1930 in farm management, cooperation, and farm organization and agricultural policy. The scope and methods of research are discussed, and a list is given of publications during the year.

History and theory of agricultural credit in the United States, E. S. SPARKS (New York: Thomas Y. Crowell Co., 1932, pp. XIII+476, figs. 3).—This is a source and textbook for classes in agricultural credit and for general readers. Agricultural credit in the United States has been traced historically with a view of finding the various sources of rural credit and making possible a clearer insight into the principles of agricultural credit as they have developed from time to time. The first five parts deal with the early flows of

capital into frontier agriculture and foreign trade and the merchant, the land banks, other important agencies that furnish long-time loans to agriculture on land mortgages, commercial banking and agriculture, and intermediate credit institutions. The sixth part discusses the question whether the farmers in the United States are amply supplied with rural credit facilities, the status of farm debt in the United States, and the present and future credit needs of agriculture.

Most of the 33 chapters are followed by questions and topics for investigation and most of them by a selected bibliography.

[Thirteenth, fourteenth, and fifteenth annual reports of the Federal Farm Loan Board, 1929-1931], A. W. MELLON, O. L. MILLS, ET AL. (*U.S. House Represent.*, 71. Cong., 2. Sess., Doc. 212 (1930), pp. III+195, figs. 2; 3. Sess., Doc. 555 (1931), pp. III+180, figs. 2; 72. Cong., 1. Sess., Doc. 36 (1932), pp. III+158, figs. 3).—These reports continue the series previously noted (E.S.R., 62, p. 283) and cover the operations of the Federal land banks, joint-stock land banks, and Federal intermediate credit banks for the years ended December 31, 1929, 1930, and 1931.

Nebraska farm mortgages, M. C. WEAVER (*Nebr. [Univ.] Studies in Business No. 30* (1932), pp. 50, figs. 2).—This includes the extent, purposes, and costs of farm mortgage debt and the length and methods of payment of loans in the State.

Between 1890 and 1930, the percentage of farm mortgages increased from 52 to 61, the debt per mortgaged acre from \$6.43 to \$21.62, and the combined value of land and buildings per acre from \$18.63 to \$55.81. The percentage of debt to value of land and buildings remained well within accepted limits of soundness, which were 50 percent of the value of the land plus 20 percent of the value of the buildings. The interest rate, which averaged 8.2 percent in 1890, dropped to 6.3 by 1915, and to 5.7 by 1920.

Research in agricultural insurance: Scope and method, J. D. BLACK ET AL. (*Social Sci. Res. Council Bul. 14* (1932), pp. [4]+63).—Agricultural insurance as a field of research is outlined in this report, which was prepared under the direction of the advisory committee on social and economic research in agriculture. The contributions were made by J. D. Black, S. B. Black, W. L. Cavert, C. H. Cyrus, H. Giese, J. A. Hodges, G. W. Hoffman, S. Johnson, H. Metzger, J. D. Pope, V. N. Valgren, and H. W. Yount.

Agricultural insurance is defined as all the different forms of insurance that are used or needed in connection with agricultural risks. Some of the forms enumerated are insurance on farm buildings and ordinary personal property against fire and lightning and windstorm and hail; farmers' automobile and truck insurance against theft, fire, windstorm, hail, collision, property damage, and public liability; livestock insurance against loss of animals by disease or accident; crop insurance against individual hazards such as hail or frost and freeze; broader forms of crop insurance against all or a stipulated variety of climatic, insect, and other hazards to which growing crops are exposed; employers' liability insurance; life insurance; and health and accident insurance for farm people.

Included are discussions of basic principles and concepts, a brief history of research in agricultural insurance, sources of data, and outlines and analyses of research projects in this field. These illustrative projects are divided into three groups. Group A includes 3 projects selected from the point of view of the insured; group B includes 12 projects selected from the point of view of the type of risk and the agencies handling it; and group C includes 4 projects,

miscellaneous in character, including relative advantages and disadvantages of insurance provided by different types of agencies, hedging as a form of price insurance, possibilities and problems involved in flood insurance, and case analysis of individual insurance companies.

This report is designed to be of specific help to research specialists and administrative officers in the development of projects in agricultural insurance.

World agriculture: An international survey (*London: Oxford Univ. Press, 1932, pp. [VII]+314, fig. 1*).—In this report by a study group of members of the Royal Institute of International Affairs, world agriculture is surveyed from the following viewpoints: Production and consumption; international trade in agricultural products; modern methods; returns from agricultural enterprise; price movements; aspects of the price fall; national aims and conditions in agriculture overseas, in Europe, Asia, and the Tropics; tariff action by individual States and by groups of countries; organization of agricultural producers for trade purposes; and international associations representing agricultural interests.

The conclusion is reached that increases in production are, by themselves, insufficient to account for the present price fall, and that the depression is primarily due to diminished purchasing power resulting from the breakdown of international exchange. The hope is expressed that the forthcoming World Economic Conference may promote world recovery and enable farmers to extricate themselves from their present plight.

Appendix 1 carries extracts from the data gathered, appendix 2 is a summary statement of the Ottawa agreements, and appendix 3 discusses direct relations between producers' and consumers' cooperative societies.

The agricultural crisis, Vol. II (*Genève (Geneva): League of Nations, Econ. Com., 1931, pp. 113, figs. 3*).—This second volume (E.S.R., 66, p. 265) is divided into two parts. Part 1 contains studies on the position of agriculture in Canada, China, Colombia, Egypt, Portugal, Turkey, and the Union of Soviet Socialist Republics. Part 2 contains reports on the spread between the prices paid to the producers and the prices paid by the consumers in Austria, Finland, Germany, Hungary, Netherlands, Norway, Poland, Rumania, Spain, Switzerland, and the United States.

An economic survey of Australia, edited by D. B. COPLAND (*Ann. Amer. Acad. Polit. and Social. Sci., 158 (1931), Nov., pp. [V]+281, figs. 19*).—The main object of this volume is to offer a survey of recent trends in Australian economic development. The contributors were requested to deal with developments up to the depression beginning in 1929. The 31 articles cover the population and economic resources, trends in production and trade, industrial organization and economic control, labor and industrial relations, public finance and State enterprise, and politics and industry—stock taking.

The following articles deal quite largely with agriculture: Sketch of Economic Geography (pp. 1-8), Growth of Population and Immigration Policy (pp. 9-17), Occupations and Urbanisation (pp. 18-25), and Survey of Production and the National Income (pp. 26-30), all by G. L. Wood; Land Utilisation (pp. 31-39), The Pastoral Industries (pp. 40-48), The Wheat Industry (pp. 49-57), and Dairying and Other Rural Industries (pp. 58-65), all by S. M. Wadham; The Export Trade and Imperial Preference, by R. Wilson (pp. 86-94); Marketing Organisation, by A. G. Whitlam (pp. 111-118); The Tariff—Its Costs and Effects, by L. F. Giblin (pp. 119-132); and The Possibilities of Scientific Research, by A. E. V. Richardson (pp. 251-258).

Agricultural regions of North America.—Part X, The grazing and irrigated crops region (Continued), O. E. BAKER (*Econ. Geogr., 8 (1932), No. 4,*

pp. 325-377, figs. 39).—This is a continuation of the article previously noted (E.S.R., 66, p. 881).

Recreational and forestry uses of land in Massachusetts, D. ROZMAN (*Massachusetts Sta. Bul. 294* (1933), pp. 20, figs. 7).—The changes in agricultural land utilization from 1880 to 1930 are traced. The extent of nonresident ownership and the relation between it and land in farms, improved land in farms, farm land values, elevation of land, and utilization of land especially for recreational purposes; State, town, and other public or semipublic forests; and possibilities of extending public ownership of lands are discussed.

The area in farms and number of farms in the State declined from 3,360,000 acres and 35,406 farms, respectively, in 1880 to a little over 2,000,000 acres and 25,509 farms, respectively, in 1930. The improved acreage in farms declined nearly two thirds. About one third of the total area in towns with less than 10,000 population is now owned by nonresidents. The greatest increase in the abandonment of farm lands and in nonresident ownership has been in the hilly and poor farm land sections. Except in coastal towns and in a few towns in Berkshire County the development of recreational uses has not encroached upon the farm land. The development of recreational uses in communities with large idle land areas has benefited the local conditions by increasing tax returns, local markets for agricultural products, and by providing some employment for local people. In some cases a negative effect was found due to the lack of interest in local institutions and competition for farm labor. Future development of good roads will result, it is believed, in a considerable amount of the idle land being used for part-time farming, recreational, and residential purposes, but the major portion will have to be used for growing trees.

Programs for land utilization in the towns and sections should be based on careful study of local conditions. It is suggested that in the acquisition of land by the State or other public institutions for forestry or recreational purposes (1) towns should not be included in which the improvement of present roads and the construction of new roads are likely to create a considerable development of part-time farming and summer homes in the near future, and (2) in towns having a major portion of the land abandoned it may be advisable to convert the entire town into a State forest by arranging for the exchange of lands in adjoining counties for lands now occupied for farming.

An economic study of Sumter County agriculture, W. C. JENSEN, B. A. RUSSELL, and M. GUIN (*South Carolina Sta. Bul. 288* (1933), pp. 72, figs. 13).—This bulletin reports the results of a study made to determine the extent to which the farmers can advantageously supply their local markets and to find the most profitable crop and livestock enterprises for the county. The survey method was used in gathering the data, and complete farm records for 1931 were obtained from 120 white and 68 negro families and special production records for 1932 from 50 white farmers. Data were also obtained from wholesale and retail grocers, housewives, boarding houses and restaurants, railroads, trucksters, hucksters, etc., and 200 records of other studies in the State were used. The people, labor, land, systems of farming, size of farms, rural credit, industry and trade, and transportation of the county are described. Analysis of the records covers the organization, size of farm, financial management, receipts, expenses, and income of the farms, farm practices, quantity inputs, costs of production of different crops and kinds of livestock, and the marketing and consumption of livestock, dairy, poultry, and field crop products, fruits, and vegetables.

The results on standard farms and with standard enterprises, special types of farms and new enterprises, operation of negro farms, marketing standards,

possible production of local market deficits, food consumption per family on the white and negro farms, and the consumption of specified fruits, berries, vegetables, and livestock, dairy, and poultry products per adult equivalent in white and negro families in the city of Sumter, grouped into families of low and medium to high purchasing power, are discussed. The 1933 outlook, the long-time outlook, and the 10-year development program are also considered.

Farm production costs in Oklahoma, 1931, P. H. STEPHENS (*Oklahoma Sta. Bul. 208 (1933), pp. 56, figs. 8*).—The findings in a study made in cooperation with the Bureau of Agricultural Economics, U.S.D.A., are reported. Data regarding the farm business were obtained for over 200 Tillman and Washita County farms in the cotton areas of the southwestern part of the State for 1929 and from 87 of the Tillman County farms for 1931. The cooperation of 61 farmers in Garfield County—a north-central county—and of 53 farmers in Craig and Mayes Counties—northeastern counties—was secured in the fall of 1930 in keeping farm account books and supplying data on crop and livestock production requirements. The general conditions existing in 1931 as regards weather, prices, and wages are described.

Tables are included and discussed showing for the northeastern and north-central counties the monthly distribution of man labor on livestock; quantities and costs of feeds fed per dairy cow, cost of butterfat production, sources of income on dairy farms; number of man hours per cow for different size herds; effect of pounds of concentrates fed per cow on production and cost of butterfat and returns per man hour; relation of butterfat production per cow to cost of production; returns per man hour and profit per cow; cost of poultry production; monthly distribution of egg production and value of eggs; tractor operation costs; horse work costs; maintenance cost of automobile or truck, combines, field machinery, and buildings other than residence; costs of operating combine; and itemized costs per bushel and net profit per acre in producing wheat, oats, barley, corn, kafir, soybeans, and alfalfa hay. The farms in some cases were grouped as horse, tractor, and horse-tractor operated farms. Other tables show for cotton in the southwestern counties for the years studied the man labor, horse work, tractor operation, and machinery costs, and the total costs and net profits per acre.

Tests of farm organization in the Turlock area, R. L. ADAMS and L. A. CRAWFORD (*California Sta. Bul. 544 (1932), pp. 128, figs. 9*).—"The purpose of this publication is to present in detail a method of making an intensive business analysis of various types of farm organizations to determine the present earning power and to test proposed changes in the existing plan of organization as these affect the earning power of the farm."

The area selected for study and its agriculture are described. The plan of procedure consisted of an account of the type of business, total acreage, net acreage in crops, utilization, farming practices, yields, and disposition of the products; a list of the necessary investment items and their costs or value; a statement of kinds and amounts of products, reported as gross, reserved for farm or home use, and net for sale; the preparation of a calendar of operations; a statement of production and maintenance outlays required for different crops and dairy and poultry products; and a financial statement drawn up to show the value of production and cost of various expenditures, and to indicate the resulting net farm income.

The types of farm organizations tested were (1) a 40-acre field-crops farm with alternative plans under conditions of (a) changes in the selling prices of products, (b) an increase in yields, (c) an increase in the size of farm, (d) the addition of a 10-cow dairy, and (e) the addition of a 500-foot poultry plant;

(2) a 40-acre fruit farm with alternative plans with changes in selling prices, increase in yields, the addition of a 500-fowl poultry plant, the selling of dried fruit instead of fresh fruit, and a 20-acre unit instead of 40 acres; (3) a 40-acre truck farm to determine the prices necessary to provide a net farm income of \$1,800, to note the effects of increasing yields, and to compare the relative incomes when sweetpotatoes were substituted for cantaloups, and to determine the effect of increasing the size of farm and the possibility of adding a livestock enterprise; and (4) a 40-acre dairy farm to determine the effect upon earnings of larger production per cow, changes in selling prices of dairy products, increased crop yields, and the effect on net income of selling manure and reducing overhead expenses.

An economic survey of the incomes, expenses, and taxpaying abilities of farmers on lands in the Merced Irrigation District, California, M. R. BENE-DICT (*California Sta., 1933, pp. [6] + 195, pls. 2, figs. 5*).—This is a mimeographed preliminary report of a survey requested by the board of directors and committees of landowners and farmers and bondholders of the district as a result of the current or prospective inability of the district to meet in full the payments of interest and bonds due or maturing. An appendix includes copies of the forms used in the survey.

A method of determining what to produce, B. HUNTER and P. A. EKE (*Idaho Sta. Bul. 195 (1932), pp. 48, figs. 7*).—The major purpose of this bulletin, prepared in cooperation with the Bureau of Agricultural Economics, U.S.D.A., is "to present a method of studying the agriculture of an area and the business of individual farms." This bulletin applies especially to the "deep soil phase" of the Twin Falls south side irrigation project.

The area and the changes in livestock, 1914–29, and in uses of land, 1913–29, are described. Tables of production standards, prices, and costs based on data for the years 1922–29 and 1931 are given and used in outlining 11 plans for operating an 80-acre farm. Tables are given and discussed, showing for the 11 plans the crop rotation and crop acreage, estimated number of livestock, estimated amount of hired labor, production of different crops, kinds of livestock and disposal thereof, capital, receipts, expenses, and labor income. Comparisons are made of the different plans and the farm income with different prices for products, and the making of a budgeting program for an individual farm is discussed.

An economic study of broomcorn production, R. S. WASHBURN and J. H. MARTIN (*U.S. Dept. Agr., Tech. Bul. 347 (1933), pp. 42, figs. 9*).—This bulletin, prepared by the Bureaus of Agricultural Economics and Plant Industry in cooperation with the State experiment stations of Illinois and Kansas, describes and discusses the changes in areas and quantity of production and in prices of broomcorn, the exports of broomcorn and brooms, the relation of supply to price, acreage needed to supply the demand, cost of production and returns, and the choice of competing cash crops. The usual field practices, the practices that should increase profits, and the costs of production in Illinois, Kansas, and Oklahoma are also described.

The annual production of broomcorn in the principal producing States, 1925–1931, varied from 31,200 to 54,700 short tons. The demand for domestic use averaged about 45,500 tons and that for export about 4,500 tons. A change of approximately 10,000 short tons from the average requirements, 1923–24 to 1931–32, resulted in a change of about \$15 per ton in price from that of the preceding year. Costs of production in 1928 in Illinois, Kansas, and Oklahoma ranged from \$91 to \$136 per ton, of which cash costs represented approximately 50 percent. The 5-year average yields for the districts studied

ranged from 295 to 583 lb. of brush per acre, of which from 274 to 488 lb. were required to pay costs, including interest. On the basis of average production and prices, broomcorn appears to have had a slight advantage over corn in Illinois. The net returns from milo in Kansas and from cotton in Oklahoma were slightly greater than those from broomcorn.

Supply, demand, and prices of California peaches, H. R. WELLMAN (*California Sta. Bul.* 547 (1932), pp. 64, figs. 23).—This bulletin supersedes the circular previously noted (E.S.R., 55, p. 688). The general conditions in the peach industry, including the production in the main peach-producing areas of the United States and in different countries and the utilization of the United States and California crops, are described. Analysis is made of the situation in the United States, and especially in California, in the canned, dried, and fresh peach industries, including the trends in production, acreages, demand, prices, exports, foreign competition, competition of other fruits, etc.

The enormous increase in the production of clingstone peaches, used mainly for canning during the past decade, resulted in a marked downward trend in the prices to both canners and growers. From 1921 to 1926 the demand increased rapidly but was offset by the increased production. Since 1929 the decline in purchasing power of consumers and in the general price level, the less rapid decline in the cost of production and canning, reduced exports, increased competition of Australian peaches in the United Kingdom market, etc., have resulted in reductions of demand, of prices to canners and growers, and of wages to both farm and cannery labor. The lower prices have resulted in a cessation of plantings, the removal of trees, and the neglect of orchards, so that production is now declining, and it is thought that the surplus situation will be corrected eventually.

The production of freestone peaches, used chiefly for drying and fresh fruit shipment, has declined. The output of dried peaches and shipments of fresh peaches have remained at approximately the same level as in former years. Prices of dried peaches have not shown a downward trend during the last decade, and with the prospects of a further downward trend in production, the industry is likely to be in a favorable position when consumers' buying power increases. Production and shipments of fresh peaches increased rapidly up to 1926. Since then there has been a gradual decline, and the trend will probably continue downward for several years. It is expected that during the coming years eastern markets will afford an outlet for a substantially larger volume of California fresh peaches than in 1931, a year of large crops in competing States.

Wool survey: A summary of production and trade in the Empire and foreign countries ([*Gt. Brit.*] *Empire Marketing Bd.* [Pub.] 57 (1932), pp. 221, pls. 10).—This, the first of two reports setting forth the results of a statistical survey by the Empire Marketing Board of the world production of and trade in wool, deals with the sheep population and production and export trade in raw wool, by countries; prices of raw wool; and miscellaneous animal fibers.

[**Second and third annual reports of the Federal Farm Board**] (*Fed. Farm Bd. Ann. Rpts.*, 2 (1931), pp. VII+95, figs. 8; 3 (1932), pp. III+110, figs. 7).—These reports continue the series previously noted (E.S.R., 64, p. 567) and cover the operations of the board for the years ended June 30, 1931 and 1932. Each report discusses the developments in cooperative marketing; surplus control methods, including stabilization operations, for wheat and cotton; production adjustments; and the organization of the board. Tables are also included relating to the board's loan operations.

Cotton marketing (*Georgia Sta. Rpt. 1932, pp. 25-27*).—A table is included showing by years 1929-32 the distribution by staple lengths of cotton ginned in Georgia prior to November 1.

Memorandum on Empire sugar policy for submission to delegates to the Imperial Economic Conference, Ottawa, 1932 (*London: Sugar Fed. Brit. Empire, 1932, pp. [2]+36*).—This memorandum submitted by the Sugar Federation of the British Empire to the Imperial Economic Conference held at Ottawa, Ont., in 1932, includes suggestions for a coordinated policy for sugar throughout the British Empire. Appendixes include a list of the members of the federation; a table showing the duties and preferences on sugar in all parts of the Empire, July 1, 1932; a statement of the State aid and subsidies accorded in the United Kingdom, Australia, South Africa, and Jamaica; tables showing the imports from and exports into countries of the Empire of raw and refined sugar; a memorandum to the Chancellor of the Exchequer in January 1932; and a table showing the duties on sugar manufacturing machinery in different countries of the Empire.

The voluntary domestic allotment plan for wheat, J. S. DAVIS (*Wheat Studies, Food Res. Inst. [Stanford Univ.], 9 (1932), No. 2, pp. [2]+23-62*).—This plan is described as launched upon the social assumptions that there is normally a balance between agriculture and industry, that it is now disturbed in a manner unfavorable to agriculture, and that agricultural recovery is a prerequisite to general economic recovery. The author raises the question whether these assumptions are entirely sound and whether social science as yet affords much foundation for social engineering. The plan is commended for the fact that it would not be likely to stimulate exports or excite retaliation and for its acreage-restriction features. Some questions are raised, however, as to whether commercial mills would run the risk of losing business through reduced flour consumption or processing in channels that could evade the tax on domestically consumed wheat. Acreage restrictions might not, in themselves, control production and might be weakened by frequent adjustments of the allotment basis or by lax enforcement. Difficulties might also be encountered in determining just when particular commodities and individuals were entitled to participate in allotment benefits.

Attention is called to the possible effects of a tax on consumption, which in the case of flour might amount to \$2 a barrel. Between the date of assured prospect of the passage of an act and the actual imposition of the tariff adjustment charge, buyers would be enabled to stock up, and these stocks would probably affect subsequent wheat purchases and prices.

The question is also raised whether the substantial transfer of purchasing power from consumers to farmers is socially justified. The plan is characterized as possessing attractive features but involving major experiments in which its complications should not be minimized or its promise exaggerated.

Organization of wheat trade in the north-western region, United Provinces, T. PRASAD (*[United Provs. Agra and Oudh, Dept. Agr.] Bul. 51 (1932), pp. [XI]+60, pl. 1*).—This is a survey of the marketing organization and methods in the upper portion of the Ganges-Jumna doab in India. The findings are discussed in chapters on the distribution of markets, communications and transportation, methods of agricultural finance, the chain of middlemen, speculation, and storage. Some suggestions are made as to means of reducing costs of marketing and stabilizing prices.

The physical volume of production in the United States, G. F. WARREN and F. A. PEARSON (*New York Cornell Sta. Mem. 144 (1932), pp. 72, figs. 43*).—Tables and charts are included and discussed showing the annual index numbers (1923-30=100), 1839-1932, of population, and of the physical volume of

production and the physical volume of production per capita of food and feed crops, total crop production, forest products, electric current, water power other than electric, coal, other fuel, fuel and power, other minerals, secondary metals, other minerals and secondary metals, all minerals and power, and total basic production with constant group weights, with constant group weights weighted by value plus value of manufacture, with variable group weights, and with variable group weights weighted by value plus value of manufacture. Other tables and charts show the rate of change of the index numbers during different periods of years and the index numbers of building construction in the United States, 1899-1932. Still other tables and charts show the index numbers of production of wheat, corn, and cotton, their relation to prices and to production of all crops in the United States and to world production.

The methods used in calculating the several indexes are discussed. Tables show Snyder's measures of physical volume of basic production, 1865-1931; Persons' index numbers of physical production in the United States, 1860-1930; and the equations of rates of change based on the authors' index numbers of physical volume of production and of physical volume of production per capita.

Research in marketing of farm products: Scope and method, J. D. BLACK ET AL. (*Social Sci. Res. Council Bul.* 7 (1932), pp. [6]+221, figs. 2).—This is one of a series of publications on scope and method in the several subfields of agricultural economics and rural sociology. Marketing as a field of research is discussed by J. D. Black and the history of research in marketing and current trends by H. B. Price and J. M. Cassels. Some 40 agricultural economists are listed as contributors to the report.

Researches in the several phases of the subject are treated under 9 group headings. Group A contains 7 typical projects relating to the structure of markets and market areas; group B, 8 projects, the consumption basis of the marketing of farm products; group C, 3 projects, market outlets; group D, 12 projects, the organization of marketing business units; group E, 11 projects, business unit operations; group F, 6 projects, government participation in marketing; group G, 5 projects, marketing institutions; group H, 3 projects, general projects by commodities; and group I, 11 projects, miscellaneous. The relation of particular projects in marketing to research in other subfields of social and natural science research is recognized.

Crops and Markets, [March 1933] (*U.S. Dept. Agr., Crops and Markets*, 10 (1933), No. 3, pp. 81-112, figs. 3).—Besides the usual market reports and price situation data, information is given regarding planting intentions as of March 1, 1933, for different crops; acreages, by States, of different crops harvested in 1931 and 1932 and indicated for harvest in 1933; and estimated prices, by States, of different farm products, February 15, 1932 and 1933.

Wholesale prices for 213 years, 1720 to 1932, I, II (*New York Cornell Sta. Mem.* 142 (1932), pp. 222, figs. 39).—Part 1, Wholesale Prices in the United States for 135 years, 1797 to 1932, by G. F. Warren and F. A. Pearson (pp. 5-200), presents the results of a study, the aim of which was "to present comprehensive index numbers to correspond with the present index numbers of the U.S. Bureau of Labor Statistics." Index numbers are given for 11 groups of commodities—farm products, foods, hides and leather, textiles, fuel and lighting, metals and metal products, building materials, drugs and chemicals, house furnishings, miscellaneous, and spirits. For the years previous to 1797, the prices obtained in part 2 were used. For the period 1880 to 1889, from 113 to 146 commodities were used, there being 116 in 1800 and 138 in 1889. For 1890 and later years, the index numbers of the Bureau of Labor Statistics, converted to the 1910-14 base, were used for the first 10 groups, and an index number was computed for spirits. A section (pp. 120-167) on the technical

details of construction of the index numbers includes descriptions and discussions of the methods of weighting of the commodity groups and of the commodities within the groups, the quantities of different commodities entering into the commerce of the United States, the methods of tabulating prices and of making computations, and the test weights used. Prices in different countries; the value of gold in England; currency price of gold in London; prices of individual commodities as compared with the general price level; and the effects of declining commodity prices on the building industry, losses on inventories, debtors, fixed charges, wages in general, unemployment, farm wages, efficiency in the use of labor, amount of farm products required to pay for a month's labor, farm management, distributing charges, the importance of marketing, and legislation are discussed. The world monetary stocks of gold and the relation of such stocks and the world physical volume of production to prices in England, United States monetary stocks of gold and the relation of such stocks and the United States physical volume of production to wholesale prices in the United States, efficiency in the use of gold, and future relationships of gold to prices are also discussed.

The tables and charts included show, among other things, the monthly index numbers of wholesale prices of all commodities with variable group weights, 1720-1932; comparison of such prices in the War of 1812, the Civil War, and the World War periods; comparison of prices in the United States with those in France and China, 1913-32; comparative price declines (or increases) from peak years to 1929 and to November 1931 in the United States, England, France, Italy, Germany, and North China; monthly index numbers of prices in England, 1885-1932, and in France, 1901-32; index numbers of wholesale prices in England, 1782-1931, and comparison of such prices during the Napoleonic and World War periods; comparison of prices in gold and in currency and value of gold in England, by years 1782-1932; currency price of gold in London, by years 1798-1821, and by months 1910-32; average monthly exchange rates on London, 1912-32; comparison of wholesale prices of all commodities in the United States and prices of hogs at New York City, 1860-84, of heavy hogs at Chicago, 1914-32, of winter wheat at New York City, 1860-84, of No. 2 hard winter wheat at Kansas City, 1914-32, and of wages, exclusive of agriculture, in the United States, 1860-90; comparison of prices of white pine and brick, 1860-91, and of yellow pine and brick, 1914-32, of rents in 5 large cities, 1860-80, and in 8 large and 10 lesser cities, 1914-32; purchasing power of hourly wages, exclusive of agriculture, 1840-1929; wholesale prices and percentage of unemployment in Great Britain, 1888-1932; comparison of wholesale prices and wages in England, 1790-1855; farm wages in different States of the United States, 1910-32; amount of wheat, milk, and eggs required to pay one month's cash wages and board in New York during different periods, 1880 to 1929; labor income, 1908 and 1928, on northern Livingston County, N.Y., farms with different crop indexes and work units per man; monthly index numbers, 1910-32, of prices paid farmers in the United States for food, of retail prices paid by consumers for food, and cost of distributing food; changes in prices of basic commodities in periods of rising and declining prices; relation between monetary stocks of gold and the physical volume of production and wholesale prices in England, 1830-1931, and in the United States, 1830-1932; and monetary gold, money in circulation, and bank deposits in the United States, 1880-1932.

Other tables and charts show the monthly index numbers, 1797-1932, of wholesale prices of all commodities with constant group weights and compare them with those with variable group weights and with those of 30 basic commodities; currency value of gold in the United States, by months 1814-17, 1837-43, and 1862-78; gold value of currency in the United States, by months

1862-78; and the monthly index numbers of wholesale prices in the United States in gold, 1862-78, with variable and constant group weights and of basic commodities.

Tables show the monthly and yearly index numbers from 1785 to 1798 to 1932 for each of the 11 commodity groups and for farm foods. Charts compare the index numbers, except for house furnishings, with those for all commodities. Other tables show for the period 1860-71 the monthly index numbers of wholesale prices of farm products and of basic commodities with cotton at full weight, and the monthly index numbers of wholesale prices of lumber, 1797-1932.

Comparisons are made of the several index numbers calculated by the authors in this study with the following index numbers: The Aldrich simple-average index; Snyder's index of wholesale prices of 14 basic commodities, 1860-1928; Cole's index of wholesale prices of 33 commodities, 1843-62, and of 38 commodities, 1825-45; Smith's index of wholesale prices of 33 commodities in Boston, 1795-1824; Roelse's index of wholesale prices, 1791-1801; an unweighted quarterly 20-commodity index calculated by the authors, 1843-91; a weighted quarterly 37-commodity index computed by the authors, 1840-91; a 147-commodity index computed by the authors, 1840-1930; and the index numbers of McNeil, Mitchell, Dun, Snider, Hurlin, and Juergens, the U.S. Bureau of Labor Statistics, and others. The computation of the several indexes, the weightings, etc., are discussed, special attention being given to the period 1840 to 1890. A bibliography is included.

Part 2, Wholesale Prices at New York City, 1720 to 1800, by H. M. Stoker (pp. 201-222) presents a series of index numbers calculated from quotations published in New York City and Philadelphia newspapers. The base period chosen was 1798-1800. The index numbers on this base were converted to the 1910-14 base to conform to those presented in part 1. Other index numbers included are a 71-commodity index for 1787-1800, and a 15-commodity index for 1720-87. The weightings of the several commodity groups and of the individual commodities in the groups are shown, discussed, and compared with the Warren and Pearson index numbers presented in part 1. Comparisons are also made of the indexes, 1720-1800, for New York City prices and the index numbers of G. R. Taylor for Charleston, S.C., Warren and Pearson and Roelse for Philadelphia, and W. B. Smith for Boston. The depreciation of currency during the period, and the agricultural development and trade of Colonial New York are described.

Price fixing in New Zealand, W. B. SUTCH (*Thesis, Columbia Univ., New York, 1932, pp. 165, figs. 4*).—"This survey covers the history of the war and postwar authoritative price-fixing and commodity control in New Zealand—its effects and effectiveness." The several chapters deal with the principles of commodity control, the control of sugar, butter, building materials, and wheat, and briefly with other commodities, including hides, footwear, petrol, potatoes, coal, milk, meat, bacon and ham, and groceries.

Appendix describe the New Zealand legislation authorizing commodity control and compare the index numbers of controlled products. A bibliography is included.

Farmers' cooperative associations in Florida, H. G. HAMILTON and M. A. BROOKER (*Florida Sta. Rpt. 1932, pp. 25-27*).—Tables are included showing the number of associations of different types active and inactive in 1929-30, with the reasons given for 129 associations for ceasing to operate.

Agricultural co-operation in Scotland and Wales (*London: George Routledge & Sons, 1932, pp. XI+246*).—This volume, the third in the series (E.S.R.,

63, p. 888; 68, p. 555), completes the exhaustive survey of agricultural cooperation in the British Isles made by The Horace Plunkett Foundation. The first part (pp. 1-174), dealing with Scotland, traces the history of cooperation and discusses the legal position of the movement; cooperative societies handling agricultural requirements and eggs; cooperative creameries; the Scottish Milk Agency; cooperative marketing of wool, livestock, meat, bacon, potatoes, raspberries, and fish; sheep stock clubs; and societies undertaking services. The second part (pp. 175-246), dealing with Wales, traces the history of cooperation and discusses agricultural requirement societies and cooperative organizations for marketing and undertaking services.

Both sections include a detailed survey, by counties, of the existing organizations.

RURAL SOCIOLOGY

Research in rural organization: Scope and method, edited by J. D. BLACK (*Sociol. Sci. Res. Council Bul. 12 (1933), pp. 160, fig. 1*).—This report was prepared under the leadership of a special advisory committee consisting of Black, C. C. Zimmerman, E. deS. Brunner, B. L. Hummel, J. H. Kolb, C. E. Lively, D. Sanderson, and H. R. Tolley. The twelfth in the series on scope and method, this publication represents the joint efforts of some 25 of the more experienced specialists in agricultural economics and rural sociological research in the United States. Preliminary to project analysis, rural organization as a field of research and the theoretical basis of such research are discussed by Black and Zimmerman. The latter also discusses the history of research in rural organization.

The type projects developed are divided into four distinct groups. Group A embraces 14 projects dealing with area and ecological organization; group B, 18 projects dealing with special-interest and related organizations; group C, 9 projects dealing with relationships of organizations to institutions and social environment; group D, 9 projects dealing with general and miscellaneous subjects, such as isolated-farm v. farm-village organization, unutilized human resources of an area, effects on social organizations of the commercialization of agriculture and the intrusion of urban residence into farming districts, the social significance of part-time farming, and utilization of leadership in social organizations.

This report is designed to be of service to administrative heads and specialists dealing with research in agricultural economics and rural sociology in the United States.

Rural social trends, E. DE S. BRUNNER and J. H. KOLB (*New York and London: McGraw-Hill Book Co., 1933, pp. IX+386, figs. 20*).—This is one of a series of monographs published under the direction of the President's Research Committee on Social Trends. The authors made a comprehensive survey of social changes which are proceeding simultaneously and interacting upon each other to an undetermined degree. They express the view that social problems arise largely from such unplanned reactions of the rapidly changing phases of social life upon the more stable phases. Among examples pointed out are changes in industrial technic which affect employment and changes in immigration policy which affect the growth of population and the demand for farm products.

The twelve chapters treat of the mobility and changing characteristics of rural population, country life and agriculture, village growth, country-village and rural-urban relationships, merchandising and credit services, the public school and education, religious agencies and services, social and recreational

organizations, rural social services, social implications of local government, and a forward-looking chapter on 1930 and after.

In six appendixes are presented the history and scope of the study, source data on rural and village population and rural-urban relations, case studies of tendencies regarding neighborhood changes, data on village and open country churches, source data on other social institutions, and social utilities and wealth.

The authors endeavor to present a clear picture of the American rural community in 1930, to contrast it with earlier conditions, and to offer suggestive explanations or interpretations of those changes that were found. The view is expressed that if men and women of all shades of opinion can find a common basis of knowledge to build upon, future social changes may be brought in large measure under the control of social intelligence.

The rural community: The natural history of a sociological group. D. SANDERSON (*Boston and London: Ginn & Co., 1932, pp. IX+723, figs. 57*).—This is a sociological study of the rural community. The object was to secure a knowledge of the forces and principles influencing the formation, persistence, and decline of various types of rural locality groups. Communities of different times and regions are classified according to structure and function into the primitive agricultural village, the village community, the modern agricultural village, and the modern rural community types.

The author traces the history, structure, economy, political organization, social institutions, social control, and causes of decline of the village community. The latter part of the book deals with the modern agricultural village and rural community, including social organization, attitudes, and control. In concluding chapters the future of the rural community and its sociological significance are developed.

Some conclusions reached are as follows: (1) The problem of the rural community group is one of both internal and external adaptation, of adjusting itself to existing environment and readjusting itself to ever new environment, to re-create environment to meet unsatisfied desires through communication, discovery, invention, science, art, and religion. The process is ever recurring and never completed. (2) The locality group as a mode of human association combines the factor of physical environment with that of human nature. (3) The modern rural community has less unity of the common will than has the village community. An advantage of the modern over the primitive village community, however, is that its common will is more potent and creative, whereas that of the village community was directed toward the maintenance of the status quo. (4) The rural community group is essential to human society. Vocationally, the farmers are attached to the land. Those who move are less likely to succeed. Acquaintance and the development of common interests in a local area are inevitable. (5) The environmental areas in which human association is frequent and intimate are greatly modified and extended with modern means of transportation and communication. The ties of history and tradition in a rural community tend to be stronger than in special interest associations. (6) The rural community acts collectively for purposes of defense. With progress the objects of defense necessarily change. Defense of the primitive village against attack of neighboring tribes, robbers, or wild animals becomes collective action against economic and social inequities and injustices in the modern rural communities. (7) No community can permanently exist without having available within the locality certain services which are essential to its life. Increased wants and greater division of labor call for larger areas for the support of highly specialized and occasional services and widen the area of the rural community. (8) The desire of the people

for sociability, recognition, and response forms a bond of the rural community. This calls for common meeting places for purposes of association within a local area. (9) For reasons indicated, the rural community becomes the most important group for social control, with the possible exception of the family. Because of interrelated interests, the rural community is both a primary group of individuals and a complex of voluntary associations. The form of the rural community changes but not the necessity for social organization of an agricultural people.

South Dakota town-country trade relations, 1901-1931, P. H. LANDIS (*South Dakota Sta. Bul.* 274 (1932), pp. 47, figs. 14).—This study, made in cooperation with the Bureau of Agricultural Economics, U.S.D.A., is based upon Bradstreet's Commercial Ratings for each fifth year, 1901 to 1931, inclusive, supplemented by Federal and State census reports, data from State departments, and correspondence with commercial firms.

Maps, tables, and graphs are included dealing with such factors as the normal annual precipitation; density of population; distribution of trade centers; number of mercantile enterprises of different kinds; percentages of rural and urban population; number and percentage of chain and independent units in trade centers of different sizes; and the relation of population to trade centers, retail stores, and chain stores.

Some of the implications of the findings of the study are as follows: (1) The farmer can, within limits, choose his trade center, and if he desires the small center his patronage is necessary; (2) if the small town disappears as a shopping center, there is danger it will also disappear as a market; (3) as the farmer participates more fully in urban modes of life, the farm home as a self-sustaining and self-determining economic and social unit declines, and it shifts its functions to the urban trade center; (4) in the absence of rural patronage, the crossroad general store will disappear, except where transient trade in gasoline and confectioneries supports it; (5) merchants must recognize the fact that the farmer now has a choice of trade centers and that trade is dependent on cultural and psychological factors as well as on neighborhood relations; (6) large towns and cities will probably supersede small towns to quite a degree in eastern South Dakota unless the small town can offer advantages that appeal to the new rural values; (7) different types of business units succeed best in different size trade centers; (8) merchants, by advertising, can radically change life habits and thus increase contacts between town and country; (9) probably the most successful trade center today is the one keeping its interests and wares before the tributary population continually by the use of the press, radio, etc.; and (10) the deflation of the farm income has dealt the rural trade center a stunning blow, prohibits the farmer from exercising many of his acquired buying habits, and is causing many farm families to return temporarily to a greater simplicity in living habits, which, if prolonged, means ruin for many merchants. This situation is bringing about a realization by both farmer and tradesman that the town is the farmer's town.

[**Papers on rural sociology presented at the twenty-sixth annual meeting of the American Sociological Society**] (*Amer. Sociol. Soc. Pub.*, 25 (1931), No. 4, pp. 3-64).—Included are the following papers presented in the rural sociology section at the meeting held at Washington, D.C., December 28-30, 1931: Proposed Method for Studying the Farm Family, by E. L. Kirkpatrick (pp. 3-9); Suggestions for a Sociological Analysis of the Rural Church, by H. W. Beers (pp. 10-17); Farmers' Co-operative Associations, by R. C. Smith (pp. 18-28); The Relationships of Mohammedan Culture Patterns to Social Processes in the Mohammedan Community in India, by J. L. Hypes (pp. 29-37);

The Influence of National Cultural Patterns on the Rural Life of Japan, by F. R. Yoder (pp. 38-44); Contrast of Some Major Elements in the Social Pattern of Rural China and Rural America, by W. A. Anderson (pp. 45-51); and The Family and Village in India, by W. H. Wilson (pp. 52-64).

AGRICULTURAL AND HOME ECONOMICS EDUCATION

Rural adult education, B. Y. LANDIS and J. D. WILLARD (*New York: Macmillan Co., 1933, pp. XIII+229*).—The results of a research project of the American Association for Adult Education are presented. The several chapters deal with the significance of rural life in American civilization, social and economic factors influencing adult education, library services, the public schools, agricultural extension, college and university extension, parent education, religious organizations, farm organizations, the cultural arts, radio programs, folk schools, and community study and organization. Part 3 discusses the main problems involved in improvement of rural adult education and the objectives of a program, and contains certain suggestions for a national program.

Fifth Ohio Dairy Day (*Ohio Sta. Spec. Circ. 42 (1932), pp. 4, figs. 5*).—A program for Ohio Dairy Day held at Wooster, August 12, 1932.

Rural school organization in Michigan, F. M. THRUN (*Michigan Sta. Spec. Bul. 229 (1933), pp. 32, pls. 6*).—Results are presented of a study of the organization and administration of the public schools of the State in relation to costs and efficiency in educational service rendered. Costs have risen until in 1930 the annual outlay amounted to some \$135,000,000.

The different kinds of school districts, including primary school, city school, graded school, township unit, rural agricultural school, and county agricultural high school districts, are discussed. Conclusions drawn from surveys of six selected counties are presented. The prevailing independent school district system is said to lack coordinated leadership in educational policies. That the district form of administration is lacking in financial efficiency is indicated by the fact that it does not permit the most efficient use and planning of school facilities. Great economies could be realized by enlarging the unit of administration. Suggested changes include flexible attendance areas; a central board empowered to prepare or review school budgets, plan new building requirements, and control the issue of bonds; supervision by an appointed county superintendent possessing proper qualifications and having greater powers than the present county commissioner of schools; centralized purchasing of supplies and equipment; and enlargement of the taxing unit. Opposition to a larger unit comes from districts enjoying a tax advantage. This opposition might be overcome by the adoption of an equalization plan by the State.

The bulletin was prepared as a report to the Michigan Commission of Inquiry into County, Township, and School District Government.

Buildings and equipment for home economics in secondary schools, M. BRODSHAUG (*Thesis, Columbia Univ., New York, 1932, pp. X+179, fig. 1*).—The evolution of home economics plant facilities, the nature of home economics education in senior and junior high schools, space allotment for different purposes, building problems, and the equipment for different lines of work are considered and suggestions made for planning the home economics department in a secondary school. Appendixes include tabulations of data gathered as to space and miscellaneous equipment, an analysis of State standards for home economics plant facilities, and a check list for evaluating objectives and topics preliminary to a study of plant facilities and equipment for home economics.

Food, M. R. FRIEND and H. SHULTZ (*New York: D. Appleton & Co., 1933, pp. XX+304, figs. 80*).—This is one of a series of beginning texts in home economics. The material in each discussed is organized for the unit plan for teaching.

The three units in this volume are food preparation, including sections on preparing the three daily meals; nutrition, including sections on fuel, protein, mineral, and vitamin needs, ridding the body of waste, and the needs of a balanced diet; and marketing, including sections on meal plans and the market list, choosing for good qualities, preventing waste in storage, cost of service, and the buyer and storekeeper. The unit on food preparation is of the practical art type and the other two of the science type.

Clothing, M. R. FRIEND and H. SHULTZ (*New York: D. Appleton & Co., 1933, pp. XX+300, pl. 1, figs. 121*).—This volume is one of the series noted above. The units used are good grooming, beauty in dress through color and design, choice of fabrics, care of clothing, and a girl's allowance.

Living in our homes, M. R. FRIEND and H. SHULTZ (*New York: D. Appleton & Co., 1933, pp. XVIII+274, figs. 94*).—This volume is one of the series noted above. The units used are cooperation in the home, a girl's room, play in our homes, and pleasure from our foods.

FOODS—HUMAN NUTRITION

Food, health, vitamins, R. H. A. and V. G. PLIMMER (*London and New York. Longmans, Green & Co., 1932, 5. ed., pp. XII+143, pl. 1, figs. 12*).—This is the fifth edition of the popular booklet formerly called *Food and Health* (E.S.R., 56, p. 791).

[**Food and nutrition studies at the Florida Station**], O. D. ABBOTT, L. W. GADDUM, and C. F. AHMANN (*Florida Sta. Rpt. 1932, pp. 92, 94, 95*).—In this progress report (E.S.R., 67, p. 619), projects on which findings are reported include studies of plant pigments as sources of vitamin A, the glucosides of citrus fruits, methods of preventing the development of rancidity in pecans, the value of improved diets in the nutrition of children with hookworm infection, and the jelling properties of several varieties of blackberries and grapes.

Edible mollusks of Manila, F. TALAVERA and L. A. FAUSTINO (*Philippine Jour. Sci., 50 (1933), No. 1, pp. 1-48, pls. 18, figs. 6*).—In this compilation of information on various species of shellfish sold and used in and around Manila, the mollusks are arranged in order of their importance by families, beginning with oysters. Inasmuch as practically all of the mollusks are sold in their shells, descriptions of the shells, with photographs, are given for each species. Notes are included on the general occurrence, habitat, and habits; the cultivation, collection, and utilization of the different families or types; and the special properties of different species under each family.

A study of the losses incurred in cooking and the factors affecting the palatability of the New Mexico pinto bean; with a later similar study of the bayo and other varieties of beans (*New Mexico Sta. Rpt. 1932, pp. 58, 59*).—This progress report (E.S.R., 67, p. 86) summarizes the findings in a study of the factors affecting the palatability of the New Mexico pinto bean on baking.

Further studies on the use of wheat bran as a laxative: Observations on patients, G. R. COWGILL and A. J. SULLIVAN (*Jour. Amer. Med. Assoc., 100 (1933), No. 11, pp. 795-802, fig. 1*).—The investigation noted previously (E.S.R., 68, p. 856) was extended to six male subjects who had suffered from constipation for a considerable period. These subjects subsisted on carefully selected and controlled basal diets throughout a period of approximately 8 to

10 weeks. At intervals the diets were supplemented with one of the products under investigation, which included commercial bran, a processed bran product, and fruits and vegetables, all furnishing definite amounts of fiber varying from 50 to 113 mg per kilogram of body weight daily. The general plan of the experiment and the criteria for laxative action were the same as in the earlier study.

One subject was unable to take fibrous roughage either as commercial bran, processed bran, or fruits and vegetables. In this subject agar agar fed at a fiber intake of about 50 mg per kilogram gave satisfactory results, but was not tolerated at a 90-mg level. In the other subjects the commercial bran and processed bran, when taken in such amounts as to bring the daily fiber intake up to 90 mg per kilogram of body weight, were effective in correcting the constipation, while the fruits and vegetables furnishing the same amount of fiber were satisfactory in only two cases. The commercial bran was slightly superior in its laxative effect to the processed bran, but was much less palatable and more difficult to ingest in reasonable quantity. In these subjects unchanged fiber recovered in the feces was much less than was the case with the healthy men studied in the earlier investigation.

"It is suggested that the tendency to constipation which these patients exhibited was due to this fact. A diet of common foods that will suffice to promote satisfactory laxation in healthy persons evidently will do so in some of these patients but not in all, and, therefore, the latter require some form of roughage that will resist all decomposition. Both commercial wheat bran and the processed bran product tested in this study were found to be satisfactory sources of fibrous roughage for these patients."

The effect of pasteurization upon the nutritive properties of milk, W. G. SAVAGE (*Lancet [London]*, 1933, I, Nos. 8, pp. 429-433; 9, pp. 485-488).—This critical review of the literature on the subject includes changes in the mineral constituents, enzymes, and vitamins produced in milk by pasteurization; the chemical composition of raw and pasteurized cow's milk and human milk; feeding experiments with raw and pasteurized milk on rats, pigs, calves, and guinea pigs, with a discussion of their validity as applied to human feeding; and human feeding experiments involving a comparison of raw and pasteurized milk and dried milk.

It is pointed out that the known changes in cow's milk produced by pasteurization are very slight and, as far as calcium and possibly phosphorus are concerned, tend to make it approximate a little more closely in composition human milk; that while animal feeding experiments furnish some evidence that pasteurized milk is less favorable than raw milk for promoting growth in animals, the calcium needs of which are equal to or greater than that of the calf, they furnish no evidence that it is less favorable for animals such as human infants whose needs for calcium are lower than that of the calf; and that there are no human experiments demonstrating that pasteurized milk is less nutritive than raw milk for young children. "For much older children, if their diet is insufficient in calcium, it is possible that the small reduction in available calcium which seems to occur with pasteurization might exert a slight retardation of growth. At the most this would be slight and probably unimportant, while at present it is only a possibility. It is too small to have any significant bearing on the value of pasteurization."

A list of 49 references to the literature is appended.

The utilization of calcium and phosphorus from various forms of milk and milk products (*Kansas Sta. Bion. Rpt. 1931-32*, pp. 144, 115).—This progress report (R.S.R., 64, p. 895) summarizes data on the relative proportions of calcium and phosphorus in different types of cheese.

Soy bean (vegetable) milk in infant feeding.—Preliminary report, F. R. RITTINGER and L. H. DEMBO (*Amer. Jour. Diseases Children*, 44 (1932), No. 6, pp. 1221-1238, figs. 8).—This report includes a review of the literature on the use of soybean milk as an infant food, a compilation of published data on the composition of soybeans, a summary of a study by H. Goldblatt of the contents of vitamins A, D, and B (complex) in a commercial soybean milk powder, results of preliminary tests of the value of soybean milk powder as an exclusive food for rats, and a report and discussion of a preliminary clinical study of the use of a specially prepared soybean milk in infant feeding.

The soybean milk powder contained 560 Sherman units of vitamin A and 28 Steenbock units of vitamin D per ounce. In the vitamin B tests the technic of Bourquin was used as regards depletion period and length of experimental period, but there was no differentiation of vitamin B₁ from B₂. A value of 22 units of the vitamin B complex per ounce was reported.

For the clinical tests, soybeans of the Mammoth Yellow variety were cleaned, washed, specially treated to remove unpleasant flavors, and converted to a milky fluid to which were added special sugars, salts, and oils to make up recognized deficiencies in the beans. The mixture was homogenized, spray dried, and packed in tin cans evacuated with nitrogen. The powder contained moisture 2.5, protein 23.69, fat 20.2, carbohydrate 48.31, total ash 5.3, and starch 0.5 percent. When reconstituted with boiled water in the proportion of 35 g of powder to 8 oz. of water, the liquid contained 3.6 percent of protein, 3.07 of fat, and 7.3 percent of carbohydrate, and had a pH value of 5.5.

The 50 infants selected for the study included breast-fed infants receiving an insufficient quantity of milk from their mothers and infants which received no other food than the soybean milk. The experiment was started when the infants were about 4 weeks old and was continued for a year. The usual supplements of cod-liver oil and orange juice were given with other supplements at the proper ages.

In general, growth and development were satisfactory on the soybean milk. The stools were of normal consistency and resembled those of the normal breast-fed infant in bacterial flora, but were much more bulky. In a few instances satisfactory gains were not made. The question is raised as to the relative availability of the soybean milk protein as compared with normal protein. To test this point nitrogen metabolism experiments are under way.

An investigation into the effect of certain factors upon child health and child weight. G. C. M. MCGONIGLE and P. L. MCKINLAY (*Jour. Hyg. [London]*, 32 (1932), No. 4, pp. 465-488).—Of particular interest in this report of the analysis of a large number of record cards of children who had attended child welfare centers in an industrial town on the northeast coast of England is the frank discussion of the limitations in such a study. It is emphasized in particular that "any attempt accurately to study the influence of any factor (such as diet) on the incidence of certain pathological conditions in childhood would require to take account of at least the three following factors: (1) The degree of any such factor, e.g., the amount of any deviation from a 'normal diet'; (2) the period of time over which the factor is operative; (3) the age of the child at which the deviation began and over which it lasted." It is admitted that the record cards available did not make possible accurate estimation of the three factors enumerated and that in such an investigation "the plan of campaign should precede, not succeed, the collection of information."

The effect of other factors upon the reliability of health records is discussed, with special emphasis on the influence of personal bias in recording information. In this connection it is considered advisable although often impractical for the

investigator who records the nature of the diet to work independently of the physician who records the clinical data.

The report proper consists of two sections, the first dealing with the incidence and possible correlation between certain conditions discovered among the 741 children whose records were studied. These included unsatisfactory diet, bone conditions, pharyngeal conditions, dental decay, squint, anemia, diarrhea, bronchitis, and otorrhea. The most significant positive correlations were shown between defective diet and bone defects, pharyngeal conditions, dental decay, squint, and anemia. The second section dealt with the relation between infant weight and certain factors, including diet, overcrowding, size of the family, maternal health, and maternal efficiency. The highest and most consistent relationship to weight of the children was the efficiency of the mother, although the method of determining this is not stated.

Physical unfitness in the preparatory school. W. R. P. EMERSON (*Amer. Jour. Diseases Children*, 44 (1932), No. 3, pp. 509-523, figs. 2).—This discussion is based upon records obtained over several years of the health status and height and weight measurements of a large number of entering students at Dartmouth College and Massachusetts Institute of Technology and of students in eight representative high schools and seven leading private schools.

Physical unfitness to an appalling degree was found, not only among students entering college and preparatory schools but also among those who had had the benefit of health programs. The explanation offered to account for the failure of present-day health programs is that the essential causes of impaired health are not found and corrected.

"The chief obstacle to health work is the persistent idea that if a person is not sick he is well, which prevents the physician from entering the field of health in the same scientific spirit in which he meets the problems of disease. Because of the failure of present health programs as indicated by the extent of physical unfitness, the plea is made that medical training should be as efficient in the diagnosis of health as in that of disease."

Some factors determining the insensible perspiration of man. F. G. BENEDICT and H. S. H. WARDLAW (*Arch. Int. Med.*, 49 (1932), No. 6, pp. 1019-1031).—Attention is called to various precautions which must be taken if insensible perspiration measurements are to be applied successfully to physiologic and clinical problems, and an investigation of the effect of various factors upon such determinations is reported, with results which are summarized as follows:

"When measured under the usual conditions obtaining in basal metabolism experiments, the rate of insensible perspiration of an adult man became constant within 30 minutes after the assumption of the lying position. Changing from the lying to the sitting position caused an increase of 20 percent in the rate of insensible perspiration under the special experimental conditions. Sleep during the daytime had no significant effect on the rate of insensible perspiration. Sleep at night lowered it markedly. About 15 percent of the total loss by insensible perspiration was due to the loss from the surfaces of the hands and feet. Of the total skin loss, 30 percent was derived from the surfaces of the hands and feet. The rate of loss from the hands and feet was approximately three times greater than that from the rest of the skin per equal unit of skin area. Heating the feet increased the loss by insensible perspiration considerably."

The authors conclude that the accurate measurement of insensible perspiration may have considerable clinical value, but that the method has its limitations which must be clearly recognized.

The importance of temperature on the survival time of bacteria in acid foods. P. J. BEARD and P. J. CLEARY (*Jour. Prev. Med.*, 6 (1932), No. 2, pp.

141-144).—Nutrient broth at pH 3.5 and 4 was seeded with strains of *Eberthella typhosa*, *Shigella dysenteriae*, and staphylococci, stored at temperatures of 37.5°, -4°, and -12° C., and tested from time to time for viability of the organisms, new tubes being used for each sample. Similar tests were carried on with orange juice at pH 3.5 inoculated in the same way and stored at -4°.

Both series of tests showed an appreciable inhibition of the bactericidal effect of acidity at low temperatures. In the orange juice the survival period varied from 50 hours for staphylococci to 170 hours for strains of *E. typhosa* and *S. dysenteriae*. "This suggests the possibility of infection by this group of organisms in highly acid foods preserved only by storage at such temperatures. This possibility of infection is increased by the fact that such foods are frequently served with little storage—indeed freshness is often made a selling point. Danger is probably decreased by the fact that massive infection of the product would be relatively rare. It follows that preparation and handling of such foods should be subject to as rigid regulations and inspection as are applied to other types of food."

The significance of phosphoric esters in metabolism, R. ROBISON (*New York: N.Y. Univ. Press; London: Humphrey Milford, Oxford Univ. Press, 1932, pp. IX+104, pls. 8, figs. 10*).—This volume consists of three lectures delivered in 1931 at the New York University and Bellevue Hospital Medical College under the auspices of the Herter Lecture Foundation. The first lecture deals with the occurrence of phosphoric esters in nature, the second with calcification of cartilage and bone, and the third, which is illustrated by numerous photomicrographs and drawings, with calcification in vitro. Literature references are given at the end of each section.

Recent research on the vitamins (*Nature [London], 131 (1933), No. 3300, pp. 118-121*).—This concise review of recent vitamin literature is intended to serve as a supplement to the summary by Drummond in lectures given in April and May 1932 (*E.S.R.*, 68, p. 704).

Preliminary report on the vitamin content of the mango, E. O. V. PERRY and S. S. SILVA (*London: Empire Marketing Bd., 1932, pp. 20*).—Three varieties of Indian mungo, Alphonso, Cawasji Patel, and Shendrya, shipped in the fresh state from India to England, were tested for vitamins A, C, and D in 1931 after preliminary tests had been conducted in 1930 on the vitamin A and C content of the Alphonso variety. The tests were carried out for the most part on the pulp only.

The three varieties showed decreasing vitamin C content in the order named. The Alphonso variety proved to be a very rich source of this vitamin, from 0.5 to 1 g daily proving sufficient for complete protection to guinea pigs during a 90-day period. The rind of this variety proved equally potent in vitamin C. The Cawasji Patel was nearly as potent, from 1 to 1.5 g sufficing for complete protection. The Shendrya variety contained very little vitamin C. Attention is called to the fact that the mango has an importance in the Tropics similar to that of the apple in temperate countries, and that the Alphonso variety contains about six times as much vitamin C as the most potent apple thus far examined, the Bramley Seedling (*E.S.R.*, 64, p. 498).

The Alphonso variety was slightly richer than the other two in vitamin A. On 0.2 g daily complete protection was secured, although growth was not equal to that of the controls receiving cod-liver oil. From the results obtained, the mango is considered to be a fairly potent source of vitamin A, resembling butter in this respect.

Vitamin D was not found in significant amounts in any of the varieties tested.

Vitamin A in the pimiento pepper, L. ASCHAM (*Science*, 77 (1933), No. 1997, p. 351).—In this brief preliminary report from the Georgia Experiment Station it is announced that in vitamin A tests according to the Sherman technic fresh, commercially canned, and dried pimiento pepper induced a growth response above the unit rate in quantities equivalent to 4 mg of the material, calculated on the dry basis, and that the dried material contained from 200 to 300 mg of carotene per kilogram.

Vitamin content of common foods (*Georgia Sta. Rpt. 1932*, p. 39).—This is a preliminary report of the content of vitamins B and C in the Puerto Rican sweetpotato, raw, boiled, and baked.

A determination of the vitamin content of some common fruits and other foods (*Kansas Sta. Bien. Rpt. 1931-32*, pp. 113, 114).—This progress report (E.S.R., 64, p. 896) summarizes data on the relative vitamin B (B_1) content of milling products made from Kansas hard red winter wheat and on four yeast breads made without milk from different milling products.

The vitamin B and G content of raw and cooked broccoli, H. E. MUNSELL and H. B. KIFER (*Jour. Home Econ.*, 24 (1932), No. 9, pp. 823-826, figs. 2).—The experiments reported were conducted in the winter on California-grown broccoli. To obtain representative samples of buds, stems, and leaves, the material was chopped finely on a glass plate with a special chopper made of safety razor blades inserted in a brass block. For the cooked sample the vegetable was prepared for cooking, weighed, cooked until tender (about 15 minutes) in a small quantity of slightly salted, rapidly boiling water, cooled, and weighed again. Any water remaining was discarded, and the cooked material was chopped in the same way as the raw.

For both vitamin B and G determinations, modifications of the Sherman-Spohn diet for determining the vitamin B complex were used. The source of G in the B experiments was 10 percent autoclaved yeast, and of B in the G experiments such an amount of an 80 percent (by weight) alcoholic extract of rice polish that 100 g of the diet contained the extract of 18 g of the rice polish. In the vitamin B experiments, quantities of 1, 2, 3, and 4 g of the raw material and equivalent portions of the cooked were used. The 3-g samples induced a total average gain in weight of 25 g during the entire test period, thus indicating that 3 g of raw broccoli contains 1 unit of vitamin B. The amount of cooked broccoli equivalent to 4 g of raw induced about the same gains in weight as 2 g of the raw material, thus indicating a 50 percent loss in cooking.

In the vitamin G test, unit gains were not secured. According to the chart, 2 g of raw broccoli induced a gain of not quite 20 g in the 8 weeks' period. The animals fed an equivalent amount of cooked broccoli gained at a somewhat lower rate. The authors conclude that broccoli contains "a measurable quantity of vitamin G", and that there is "slight destruction of this vitamin during cooking."

The content of vitamin B_1 in the organs of white rats on normal and vitamin B-free diets [trans. title], H. G. K. WESTENBRINK (*Arch. Néerland. Physiol. Homme et Anim.*, 17 (1932), No. 4, pp. 560-577, figs. 8).—Various organs of normal rats and of paired rats which had subsisted for definite lengths of time on a vitamin B (B_1)-free ration were fed to other paired rats as the sole source of vitamin B, and the relative content of vitamin B in the various organs was estimated by comparisons of the growth curves of the animals receiving corresponding organs of the normal and the experimental animals. As thus determined, the liver, kidney, and heart were found to have the highest content of vitamin B after the first week of deficiency, followed by the brain and then by the muscles, tongue, spleen, stomach, and intestines.

All of these organs with the exception of the brain lost the greatest part of their vitamin B content during five weeks' subsistence on the vitamin B-free ration.

The retention of vitamin B in the brain is thought to point to this organ as the primary seat of the action of this vitamin, as suggested by the studies of Gavrilescu and Peters (E.S.R., 67, p. 634). It is indicated that further studies of the mechanism of the action of vitamin B should be concentrated on the brain.

Vitamin C in canned citrus products, C. R. FELLERS and P. D. ISHAM (*Jour. Home Econ.*, 24 (1932), No. 9, pp. 827-832, figs. 4).—The products tested at the Massachusetts State College included canned orange juice, orange slices, grapefruit juice, and grapefruit slices and fresh orange juice and grapefruit juice. The oranges and grapefruit were grown and canned in Orlando, Fla. The canned products were taken from grocers' stock at Buffalo, N.Y., and were from 7 to 10 months old when examined. The fresh juices were expressed from Florida fruits bought in the public market at Amherst, Mass., during August and September and thus had undergone from 6 to 9 months' storage.

The canned orange juice was fully protective to guinea pigs in daily doses of 1 g over the 90-day experimental period. The other three canned products were slightly less effective, but from the excellent growth and complete protection on 2-g doses it is estimated that slightly more than 1 g of these products would be sufficient for complete protection. The freshly expressed juices were fed at the 1.5-g level. Protection against scurvy was secured with both orange and grapefruit juice, but growth and physical condition were slightly inferior on the grapefruit juice.

In explanation of the excellent results with the canned citrus products, the authors suggest that the hermetically sealed tin can prevents oxidation of vitamin C.

The determination of vitamin C (antiscorbutin) in milk [trans. title], B. BLEYER (*München. Med. Wchnschr.*, 80 (1933), No. 7, pp. 257, 258).—A summary is given of the results obtained in testing various types of milk for antiscorbutic activity by the Tillmans reducing test (E.S.R., 69, p. 7). The data, when given numerically, are in terms of titration values representing the number of cubic centimeters of the indicator required to complete the titration of 100 cc of the milk.

The titration value of human milk was highest in the colostrum and decreased to a fairly constant level after about a month of between 40 and 50 cc. Cow's milk showed greater variation than human milk, but averaged about 20 to 25 cc, or about half that of human milk. In certain instances human milk was about four times as high in vitamin C as market milk. Transportation and storage were more destructive to the vitamin C content of cow's milk than quick scalding as practiced in the home. Pasteurization by the holding process proved more destructive than heating to the boiling point for a short time. The nature of the container in which milk is stored, shipped, or treated was found to have considerable influence on the stability of the vitamin.

Nickel, chromium, and aluminum were without effect and copper and silver quite destructive. Heat increased the destructive effect. The drying of milk by the roller process was less destructive of vitamin C than by the spray process. Irradiation of dried milk to increase its vitamin D content tended to destroy vitamin C. Sweetened condensed milk was richer in C than unsweetened. Various buttermilk products on the market contained relatively high proportions of vitamin C.

Titration values for fresh milk from other animals on the same satisfactory feed were goats 22 to 28 cc, sheep 3 to 4, and asses 150 cc. Camel's milk was reported as having values twice that of cow's milk.

Some sources of vitamin C in India, Part II (Continued) (*Indian Jour. Med. Res.*, 19 (1931), No. 2, pp. 393-413, figs. 8; 20 (1932), No. 1, pp. 89-106, figs. 10).—The two papers noted below are in continuation of an earlier study¹.

The antiscorbutic values of the fruits, R. C. Wats and W. I. White (pp. 393-413).—In the feeding experiments on guinea pigs reported, the basal diet used consisted of bran and crushed oats with crushed or ground chick-pea or gram (*Cicer arietinum*) in place of heated milk. Contrary to the present custom of using animals weighing only about 300 g, most of the test animals weighed 400 g or more, some over 700 g, at the beginning of the experiment. This fact, together with the use of but a single animal for a given amount of the material tested, makes the results of little quantitative value.

The fruit which appeared to be richest in vitamin C was the pomelo (*Citrus decumana*), 1 cc of the juice of which afforded complete protection. Next in order was pineapple (*Bromelia ananas*). The peeled fruit was fed in 1-, 3-, and 7-g amounts, and complete protection was secured with 3 g. Peeled bananas (*Musa paradisiaca*) were fed in amounts of 5, 10, and 15 g, with complete protection on the smallest amount. The results with oranges did not compare favorably with published data, for 10 cc of juice was required for protection. The juice of sweet limes (*C. medica limetta*) was tested in amounts of 1, 3, and 5 cc daily, and protection was not secured with even the largest amount. Pomegranates (*Punica granatum*) and pears (*Pyrus communis*) were also very low in vitamin C, for amounts as high as 20 cc of pomegranate juice and 10 g of the peeled fruit of pears afforded no protection.

Germinated pulses, tomatoes, mangoes, and bananas, R. C. Wats and C. M. E. Eyles (pp. 89-106).—The pulses tested for their germinating properties included the chickpea (*Cicer arietinum*), peas (*Pisum sativum*), mung (*Phaseolus mungo*), urd (*P. mungo radiatus*), lobia (*Vigna catjang*), and soybean (*Glycine hispida*). These were soaked for 24 hours and then allowed to stand at room temperature for 24 hours between layers of moist lint. Only a small percentage of the lobia and soybeans germinated. In the others the percentage varied from 65 percent in the case of urd to 90 percent in the peas. The germinated soybeans were not tested for vitamin C. The others were fed in amounts of 3, 4, and 5 g daily. None of the animals grew normally, and protection against scurvy was secured only with the germinated mung beans in amounts of 3, 4, and 5 g, urd 4 and 5, and lobia 5 g.

Ripe green and red bananas, varieties of *M. sapientum*, were fed to groups of 3 animals each in amounts of 5, 10, and 15 g of the pulp. Scurvy was prevented with 10 g of the red pulp, but even 15 g of the green proved insufficient.

The tomato (*Lycopersicum esculentum*) tested was described as about the size of a large plum, deep red in color, and uniformly round. Amounts of 3, 5, and 7 cc of the juice were fed, with protection in the case of the two larger doses.

The mango (*Mangifera indica*) tested was locally called "nettiya" and described as having no fiber in the pulp. Ten cc of the pulp afforded complete protection.

Vitamin-D in cacao beans (*Jour. Soc. Chem. Indus., Chem. and Indus.*, 51 (1932), No. 49, p. 1008).—A brief note stating that a sample of raw ground cacao bean (with shell removed) was found by K. H. Coward to have a vitamin D potency of one unit (E.S.R., 59, p. 689) per gram.

¹ Some sources of vitamin C in India, Part I, R. C. Wats. *Indian Med. Gaz.*, 64 (1929), pp. 79-85, figs. 5.

Lesions of the nervous system in vitamin deficiency.—I, Rats on a diet low in vitamin A, H. M. ZIMMERMAN (*Jour. Expt. Med.*, 57 (1933), No. 2, pp. 215-228, pls. 4).—Observations of marked weakness and incoordination of the extremities in rats on diets deficient in vitamin A led to macroscopic and microscopic studies of the tissues of the central and peripheral nervous systems of rats suffering from this deficiency. Seven groups, comprising a total of 23 animals, were used. The conditions of the experiment varied in the different groups with respect to the diet of the mothers during pregnancy and lactation and the stage of deficiency at which the experimental animals were sacrificed for examination. Staining methods were selected to give both a positive (Marchi and Scharlach R preparations) and a negative (Spielmeyer preparations) picture of any possible degeneration in the medullary sheaths.

On gross examination no abnormalities could be detected in the brain, spinal cord, peripheral, or optic nerves of any of the animals. On microscopic examination, no abnormalities could be detected in the optic nerves or, with the exception of one animal, in the brain. The changes in the nervous system observed microscopically are summarized as follows:

"Degeneration of the medullary sheaths of the brachial plexuses and sciatic nerves, and less often of the vagus nerves. . . . Degeneration of the medullary sheaths of the sensory tracts on the periphery of the spinal cord and in the posterior columns. . . . Changes of the same nature in the posterior nerve roots and less frequently in the anterior nerve roots of the spinal cord."

The examination of the tissues of animals killed at various stages of the deficiency and recovery showed that the lesions were not present for any appreciable period preceding the onset of clinical signs of muscular weakness and incoordination, but were present to a marked degree for a short but undetermined period following clinical signs of recovery from the nervous disease.

Attention is called to the fact that the ration employed contained no cereals which might have contributed a toxic substance to account for the degeneration of the myelin sheaths, and that a deficiency in unsaturated fatty acids did not appear to have played any role.

The effect of parathyroid hormone and of irradiated ergosterol on calcium and phosphorus metabolism in the rat, L. I. PUGSLEY (*Jour. Physiol.*, 76 (1932), No. 3, pp. 315-328, figs. 11).—In this contribution to the question of the relationship of the parathyroid hormone and vitamin D to calcium and phosphorus metabolism, a comparison was made of the effects of parathyroid hormone and large doses of irradiated ergosterol on calcium and phosphorus excretion in adult rats. Other experiments included the effect of parathyroid hormone upon the serum calcium of adult rats, of irradiated ergosterol on the phosphorus and calcium excretion in rats refractory to parathyroid hormone, of the urine of immune rats receiving parathyroid hormone on the calcium excretion of responsive rats, and of the injection of serum of immune rats upon the response of normal rats to parathyroid hormone.

The injection of parathyroid hormone in doses of from 5 to 20 units daily led to an increase in serum and fecal calcium and urine phosphorus and a relatively more striking but transient increase in urine calcium. The oral administration of irradiated ergosterol in doses of 20,000 to 50,000 units daily led to an increase in urine calcium but a decrease in fecal calcium and phosphorus. A further difference between the action of the two agents was shown in the apparent immunity of rats to parathyroid but not to irradiated ergosterol. This immunity developed quite rapidly, but animals almost completely immune to parathyroid were still responsive to irradiated ergosterol.

It is concluded that "if large doses of irradiated ergosterol do stimulate parathyroid secretion, this is but a small part of their pharmacological action."

The effect of irradiated ergosterol on calcium and phosphorus retention in children, C. B. WELD and J. F. SYKES (*Roy. Soc. Canada, Trans., 3. ser., 26 (1932), Sect. V, pp. 81-88*).—Calcium and phosphorus balances were determined in six growing children receiving a diet somewhat restricted in calcium but otherwise adequate. The diet was given unsupplemented with vitamin D for 5 weeks, and in the case of four of the subjects supplemented during the succeeding 5 weeks by 50 Steenbock units daily of irradiated ergosterol.

No significant differences were noted in the retention of calcium or phosphorus as the result of the addition of vitamin D. The calcium balances were negative in all cases but one. This subject was older than the others and her diet throughout the whole experiment had been increased by one third over that of the others.

The effect of irradiated ergosterol upon the absorption of calcium, N. B. TAYLOR and C. B. WELD (*Roy. Soc. Canada, Trans., 3. ser., 26 (1932), Sect. V, pp. 9-12, figs. 2*).—This report and the two noted below are preliminary communications dealing with various phases of the problem of the mechanism of the action of irradiated ergosterol as determined by experiments on dogs. In the present report a few data are presented on the calcium excretion in young dogs on adequate and rachitic diets supplemented by varying but not excessive amounts of irradiated ergosterol. No evidence was obtained of increased absorption of calcium. On the contrary, there was definite indication of increased excretion of calcium even in small doses and of a decided increase in excretion on larger doses.

The effect of small (therapeutic) doses of irradiated ergosterol upon the serum calcium, N. B. TAYLOR and C. B. WELD (*Roy. Soc. Canada, Trans., 3. ser., 26 (1932), Sect. V, pp. 13-16, figs. 4*).—The evidence presented indicates that small doses of irradiated ergosterol by mouth, or larger doses subcutaneously, invariably cause a depression in serum calcium as an initial effect.

The administration of irradiated ergosterol to dogs with biliary fistulae, N. B. TAYLOR, C. B. WELD, and J. F. SYKES (*Roy. Soc. Canada, Trans., 3. ser., 26 (1932), Sect. V, pp. 29-31, fig. 1*).—The possibility is suggested that bile is necessary for the absorption of irradiated ergosterol in dogs with biliary fistulae. The administration of irradiated ergosterol by mouth was not followed by hypocalcemia or any other sign of overdosage. When the ergosterol was injected intravenously, a rise in serum calcium was induced in some of the animals but not in others. Bile collected from animals receiving the ergosterol by mouth had no antirachitic properties, while that from animals treated intravenously was definitely antirachitic.

The absorption of irradiated ergosterol by bile is thought to afford an explanation of various phenomena connected with its administration. The prolonged effect of a single dose can be explained by the excretion of the irradiated ergosterol into the bowel and its reabsorption by the bile. "The varying degrees of susceptibility between different species and individuals of the same species may possibly find an explanation in the variability of absorption. The relatively low curative power of irradiated ergosterol in some cases of rickets in infants may also be a matter of defective absorption."

The mobilization and excretion of calcium following overdosage with irradiated ergosterol, N. B. TAYLOR and C. B. WELD (*Brit. Jour. Expt. Path., 13 (1932), No. 2, pp. 109-127, figs. 2*).—In this contribution to the disputed question as to the source of excess serum calcium following overdosage with irradiated ergosterol, experimental evidence obtained for the most part on dogs is reported, leading to the following conclusions:

"The hypercalcemia following large doses of irradiated ergosterol is due to the withdrawal of calcium from the skeleton. Ergosterol overdosage de-

presses the power of the intestine to excrete calcium. The calcium mobilized from the bones accumulates in the serum. A certain level of serum calcium having been reached, an increase in the urinary calcium follows. Ergosterol in the amounts which produce hypercalcemia does not increase absorption of calcium from the intestine."

Effect of sunshine through window glass and fresh air on resistance to infection: Experiments on animals, J. R. ROSS, E. C. ROBERTSON, and F. F. TISDALL (*Amer. Jour. Diseases Children*, 45 (1933), No. 1, pp. 81-95, figs. 6).—Data are reported showing that "the exposure of rachitic rats to sunshine transmitted by common window glass outdoors markedly raises their resistance to an oral infection with 'rat typhoid', although the rickets is not improved. The beneficial effect of exposure to fresh air alone is approximately half that of the combination of fresh air and sunshine through glass. The addition of vitamin D to this rachitogenic diet also increases the resistance of the rats to the infection, and if they are exposed to sunshine under window glass as well, the resistance is still further raised."

The authors conclude that "the vital radiations from the sun should not be limited to the narrow band in the short ultraviolet region, which is anti-rachitic. The foregoing results show definitely that rays longer than those that are necessary to prevent or cure rickets have a marked effect on the animal organism, as evidenced by a decided increase in the resistance to infection."

Efficiency of New Orleans sunshine in preventing rickets in rats, H. LAUBENS and H. S. MAYERSON (*Amer. Jour. Diseases Children*, 45 (1933), No. 1, pp. 66-80).—The seasonal changes in the antirachitic activity of New Orleans sunshine and skyshine over a period of 2½ years were measured biologically by suitable exposure of rats on a rachitic diet and physically by means of a pyrheliometer and a spectrograph. Some of the animals were also exposed behind Vitaglass, Corex D, and Cel-O-Glass.

The average length of daily exposure to sunshine (sun plus sky) required to prevent rickets in rats was from 2 to 3 minutes from April through October and from 5 to 6 minutes from November through March. Exposures through the three types of special glass were also effective, although somewhat longer times were required. The average time required for protection by exposure to skyshine alone was from 16 to 17 minutes daily from May through September, from 22 to 28 minutes from October through February, and from 16 to 20 minutes during March and April. Correspondingly longer exposures under Vitaglass and Corex D were effective, but Cel-O-Glass was effective only through the summer months.

Rickets: Comparative value of several light sources for cure and prevention, A. KNUDSON (*Amer. Jour. Diseases Children*, 44 (1932), No. 3, pp. 531-541, fig. 1).—Comparisons are reported of the antirachitic potency, as determined by preventive and curative experiments with rats, of several light sources and of winter and summer sunshine in Albany, N.Y. The agents tested and the minimum daily exposure required for the cure and prevention of rickets, respectively, were as follows: Victor Uviarc, operating at 70 v at a distance of 3 ft., 60 and 20 seconds, and G.E. sunlamp, type S1 bulb, 30 and 7 minutes, respectively; exposure to sunshine in June and July 1930, 120 and 30 minutes, in June and July 1931, 90 and 20 minutes, and in January and February 1931, 1,080 (calculated) and 270 minutes, respectively; CX lamp, 60 w, 24 hours at 9 in. and 24 hours at 18 in.; and CX lamp, 500 w, 11 hours at 18 in. and 11 hours at 36 in., respectively. An addendum states that the S2 Mazda sunlamp has been found to have from one fifth to one sixth the potency of the S1 sunlamp.

It is noted that the effectiveness of the sunshine in Albany in winter is approximately the same as reported by Tisdall and Brown for Toronto (E.S.R., 58, p. 495), but that the summer sunshine in Albany is approximately 10 times as effective as in winter, while that of Toronto was reported to be approximately 8 times as effective.

Seasonal variation of antirachitic effect of sunshine in the latitude 42°39' (Albany, N.Y.), A. KNUDSON (*Soc. Expt. Biol. and Med. Proc.*, 30 (1932), No. 1, pp. 66-68, fig. 1).—This investigation has been noted essentially above. Commenting upon the applications to human beings of the findings with rats, particularly the small area of the skin which it is necessary to expose, the author expresses the opinion that "it should be possible to obtain ample radiation in this vicinity for the prevention of rickets for at least 8 to 10 months of the year by exposure of the face and hands to sunshine."

Amount of ultraviolet radiation needed to cure rickets with respect to area of skin exposed, A. KNUDSON (*Amer. Jour. Diseases Children*, 44 (1932), No. 3, pp. 524-530, figs. 2).—Essentially noted from a preliminary report (E.S.R., 67, p. 636).

The use of autolyzed liver in the treatment of pernicious anemia: A preliminary clinical report, W. F. HERRON and W. S. McELLROY (*Jour. Amer. Med. Assoc.*, 100 (1933), No. 14, pp. 1084-1086, fig. 1).—This report covers 13 cases, supplementing a preliminary report announcing the effectiveness of autolyzed liver in the treatment of pernicious anemia (E.S.R., 68, p. 281). It is of interest that the requirement of autolyzed liver by mouth approaches the intramuscular requirement of other liver preparations.

Treatment of pernicious anemia: Effect of a single injection of concentrated gastric juice (addisin), R. S. MORRIS, L. SCHIFF, J. H. FOULGER, M. L. RICH, and J. E. SHERMAN (*Jour. Amer. Med. Assoc.*, 100 (1933), No. 3, pp. 171-173, figs. 4).—Further evidence is given of the remarkable effects obtained in the treatment of pernicious anemia with single doses of concentrated gastric juice (addisin) from swine (E.S.R., 68, p. 869). In the two case reports given the material was administered by intramuscular injection. In one case, 3,200 cc of swine gastric juice was reduced to a volume of 5 cc and in the other 5,700 cc to a volume of 8.5 cc for the single injection. In each instance the injection was followed by intense stimulation of the bone marrow and marked subjective improvement.

"In the light of our limited experience, it seems probable that a product can be obtained from the gastric contents of swine of such potency that a single intramuscular injection may be sufficient to bring about a complete remission in pernicious anemia. Should this prove to be true, it seems not unreasonable to predict that one injection of potent material at intervals of two or more months may be all that is required in this disease to maintain the blood count and the hemoglobin at normal levels."

Anemia of pregnancy: Relation to anemia in general, V. C. ROWLAND (*Jour. Amer. Med. Assoc.*, 100 (1933), No. 8, pp. 537-540).—Two types of anemia of pregnancy are discussed—(1) pernicious or hyperchromic anemia, which is attributed to a relative or temporary deficiency of the intrinsic factor in gastric juice during pregnancy, and (2) secondary or hypochromic anemia, which is attributed to dietetic deficiency and faulty absorption of hemoglobin-forming substances on account of gastro-intestinal disturbances. It is thought that these anemias occur in slight degree in the majority of American women during pregnancy.

"Intelligent management of pregnancy must include a check-up on the condition of the blood and, when there is any degree of anemia, a supervision of the diet, the administration of iron in the secondary or hypochromic form, and the

use of liver extract promptly on the appearance of evidence of the rarer pernicious form or in pregnancy anemia, which is refractory to treatment by iron."

Minimum cost dietaries for diabetic patients, W. A. GROAT and M. I. ROSBROOK (*Jour. Amer. Med. Assoc.*, 100 (1933), No. 8, pp. 566-568).—Included in this paper are a minimum cost dietary in use in welfare work in Syracuse, N.Y., a diabetic dietary with six modifications developed from the minimum cost dietary, and sample menus and diet lists based upon the basic diabetic dietary.

Miscellaneous studies on the iodine and goitre problem in New Zealand, C. E. HERCUS and H. A. A. AITKEN (*Jour. Hyg. [London]*, 33 (1933), No. 1, pp. 55-79, figs. 4).—Included among the findings reported in this extension of the investigation noted previously (E.S.R., 67, p. 487) are data on the content and nature of the iodine present in some New Zealand seaweeds and sea fish; variations in the iodine content of the blood of rabbits during anesthesia, together with in vitro studies of the effect of chloroform and ether on the permeability of blood erythrocytes to potassium iodide, thyroxine, and saline thyroid extract; experimental goiter and iodine balance in rabbits; a comparison of urinary iodine excretion of goiter-free Samoans with that of inhabitants of a goiter endemic center in Christchurch, New Zealand; the incidence of goiter in a mental hospital in the latter locality; and the iodine content of pigs' thyroids in Otago, New Zealand.

TEXTILES AND CLOTHING

The colloid aspects of textile materials and related topics (*Faraday Soc. Trans.*, 29 (1933), No. 1, pp. 6-13, 65-77, 132-211, 218-279, 300-347, pls. 7, figs. 52).—Papers presented at the colloid meeting held at the University of Manchester, September 21-23, 1932, and concerned with various phases of research with natural fibers included: The Fine Structure and the Mechanical Properties of Fibres, by H. Mark (pp. 6-13); Relations between the Refractive Indices and the Behaviour of Cellulose Fibres, by J. M. Preston (pp. 65-77); Protein Structure and Protein Hydration, by D. J. Lloyd and H. Phillips (pp. 132-148); The Constitution of the Keratin Molecule, by J. B. Speakman and M. C. Hirst (pp. 148-172); The Electrical Resistance of Wool Fibres, by M. C. Marsh and K. Earp (pp. 173-193); Some Problems in the X-ray Analysis of the Structure of Animal Hairs and Other Protein Fibres, by W. T. Astbury (pp. 193-211); Contribution to the Study of the Degree of Ripening of Cotton, by O. Roehrich (pp. 218-228); The Modification of Natural Cotton Cellulose by Swelling and by Degradation, by S. M. Neale (pp. 228-238); The Physical Significance of Crimp or Waviness in the Wool Fibre, by S. G. Barker (pp. 239-250); A Discussion of Surface Tension and Dehydration as Contributory Agencies for the Production of Crimp, by E. Hill (pp. 251-257); Chemical Considerations in Relation to the Study of Mammalian Hair Growth—Part I, The Sulphur Economy of Animal Fibre Production, by A. T. King (pp. 258-271), and Part II, Observations on the Chemico-Histological System in Follicle Activity, by A. T. King and J. E. Nichols (pp. 272-279); The Swelling of Silk, by W. S. Denham and E. Dickinson (pp. 300-305); The Tensile Properties of Silk Filaments, by W. S. Denham and T. Lonsdale (pp. 305-316); Note on the "Regain" of Silk of Different Origins, by W. S. Denham and A. L. Allen (pp. 316, 317); Some Observations on the Chemical Degradation of Linen Cellulose, by C. R. Nodder (pp. 317-326); and On the Theory of the Dyeing Process—The Influence of Acid-Dyes on Animal Fibres, by E. Elöd (pp. 327-347).

The effect of sunlight and other factors on the strength and color of cotton fabrics, M. A. GRIMES (*Texas Sta. Bul. 474 (1933), pp. 56, figs. 27*).—White and colored cotton fabrics, including muslins, zephyr gingham, suiting, and voiles, were exposed to sunlight for 25 to 375 hours in 25-hour periods, and in all cases changes in breaking strength and in color occurred, although the loss in strength was not at the same rate or to the same extent in all fabrics. The average loss in breaking strength after 375 hours of exposure ranged from about 8 to 47 percent in the warp and from 18 to 58 percent in the filling. Zephyr gingham and suitings which were dyed with vat dyes usually lost less strength than did the voiles dyed with direct dyes. Dark colors, in general, were less weakened than light colors, probably due to the increased protection given by the vat dyes when in higher concentration and to greater resistance to penetration by light waves which produce tendering. Coarse, hard twisted yarns, in general, were less tendered than fine, soft twisted yarns, mercerized fabrics less than unmercerized, and unbleached less than bleached fabrics. Some of the sizes and finishes seemed to have a tendering effect.

Hours of exposure had a much greater effect than other environmental factors upon loss in strength, and temperature was next, accounting for nearly twice as much change as did relative humidity. Of the structural factors, only percentage take-up and ply significantly affected the change in strength. Much more of the change in strength was due to environmental factors than to structure.

Comparisons of the random, the random-Latin square, and the systematic random method of sampling showed that the last named method, used in the study, in which a sample comprised nine specimens, gave sufficiently accurate results.

Spectrophotometric analyses made before and after exposure to sunlight showed that all fabrics, whether white or dyed, changed somewhat in color. Unbleached fabrics became lighter and bleached undyed fabrics became grayer and more yellow. Dyed fabrics varied in the type and extent of color change, some becoming lighter, some darker, and some darker and then lighter, while others changed in tint. No one color could be said to be more fast than others. Fastness depends on the nature of the individual dye and not its hue. Fabrics dyed with vat dyes, the zephyrs and suitings, were more fast than voiles dyed with direct dyes. Dark colors appeared to fade less than light colors. Guaranteed fabrics, zephyrs and suitings, were less faded than the nonguaranteed voiles. Price did not measure fastness or retention of strength. The classifying of fadings by direct observation, giving each fabric a class number, was found unsatisfactory. It appeared that when at all possible, objective measurements of colors should be made.

The ultraviolet radiation of the sunlight at College Station was observed to be approximately one third greater than reported at Chicago, somewhat more than at San Juan, Puerto Rico, and approximately three times as much as at Honolulu, and, therefore, the sunlight at the station probably causes more tendering of fabrics and greater fading of certain dyes than at the other three localities.

The results obtained emphasized the importance of avoiding unnecessary exposure of cotton fabrics to sunlight, particularly where the ultraviolet radiation of the sunlight is great. For the least loss of strength when exposed to sunlight, a cotton fabric should be composed of unbleached, mercerized, coarse, hard twisted yarns, and if dyed, a vat dye with protective characteristics and high in concentration should be used. The desirability of buying materials guaranteed to be color fast was evident.

HOME MANAGEMENT AND EQUIPMENT

The rural homemaker in Washington County, frequency of paid work and its effects upon her and her home (*Rhode Island Sta. Rpt.* [1932], pp. 51, 52).—A brief summary is given of the analysis of the records of paid work done by 624 rural home makers in the State, including correlations between the amount of education and the cash income of the home makers.

Comparison of the methods of refrigeration in the rural home in Rhode Island (*Rhode Island Sta. Rpt.* [1932], pp. 52, 53).—A brief summary is given of a comparison of the operation costs and efficiency of temperature, both in degree and evenness, of ice refrigerators and mechanical refrigerators operated by kerosene and electricity.

A comparison of cooking equipment for the farm home (*Kansas Sta. Bien. Rpt.* 1931-32, pp. 115, 116).—This progress report summarizes the results obtained in a study of some of the factors affecting the efficiency of top burners on kerosene stoves as determined by the fuel consumption and the time required to bring water to the boiling temperature.

Higher efficiency in domestic heating, H. J. DANA and H. H. LANGDON (*Northwest Sci.*, 6 (1932), No. 3, pp. 90-97, figs. 2).—Studies conducted at the Washington State College are reported briefly. These showed that hand firing in the usual type of household furnace yields a very low over-all fuel efficiency of from 30 to 40 percent. The use of a stoker will improve this efficiency between 10 and 20 percent. Replacing the conventional furnace with an improved design of furnace having better combustion space and more adequate heat exchanger gave an efficiency of 82.5 percent, using less than half the coal to heat the same house at 33.7 percent. The addition of a hot air economizer to a conventional hot water, stoker-operated furnace, yielded an over-all average efficiency of 87.2 percent, the additional heat being extracted from the flue gases.

High efficiency, namely, 90.2 percent, was obtained during the stoker operating period, but this was reduced by the long coasting period to an average of 87.2 percent for the entire cycle, showing the desirability either of burning the fuel as fast as it is introduced, or of maintaining continuous stoker operation with varying rate of combustion.

MISCELLANEOUS

Report of the director [of Connecticut State Station] for the year ending October 31, 1932, W. L. SLATE (*Connecticut State Sta. Bul.* 347 (1933), pp. 269-288).—The experimental work not previously referred to is for the most part noted elsewhere in this issue.

Annual Report [of Florida Station], 1932, W. NEWELL ET AL. (*Florida Sta. Rpt.* 1932, pp. 218+VIII, figs. 29).—The experimental work not previously referred to is for the most part noted elsewhere in this issue. Meteorological observations are also included (pp. 149, 157, 167-173), calling attention especially to the unusually mild winter of 1931-32 in the Everglades as in other parts of the country.

Forty-fifth Annual Report [of Georgia Station], 1932, H. P. STUCKEY (*Georgia Sta. Rpt.* 1932, pp. 55, figs. 16).—The experimental work not previously referred to is for the most part noted elsewhere in this issue.

[Biennial Report of Kansas Station, 1931-32], L. E. CALL (*Kansas Sta. Bien. Rpt.* 1931-32, pp. 139, figs. 3).—The experimental work not previously referred to is for the most part noted elsewhere in this issue.

Fortieth Annual Report [of Minnesota Station], 1932, A. BOSS (*Minnesota Sta. Rpt. 1932*, pp. 77).—In addition to data noted previously or elsewhere in this issue, this report contains abstracts of the following: Preliminary Studies of the Internal Structures of *Braula coeca* Nitzsch, by E. C. Alfonsus and E. Braun (p. 15); Breeding Wheat for Baking Quality, by C. H. Bailey and H. K. Hayes (p. 16); Free and Bound Water in Elastic and Non-Elastic Gels, by I. D. Jones and R. A. Gortner (p. 18); Thiocyanogen Number and Its Application to Studies on Lard, by L. Zeleny and C. H. Bailey (pp. 23, 24); The Inadequate Distribution of State Agricultural Experiment Station Bulletins to Foreign Countries, by J. G. Leach, H. Macy, and C. H. Bailey (p. 25); Effect on the Agglutination Reactions of Bovine Sera of Variations in Concentration of Sodium Chloride in Rapid-Test *Bact. abortus* Antigens (p. 26), The Effect on the Agglutination Reactions of Bovine Sera of Variations in Bacterial Concentration of Antigens for Use in the Rapid Agglutination Test for the Diagnosis of Bang's Disease (p. 26), The Influence of Some of the Properties of the Serum-Antigen Mixture on the Results Obtained with the Rapid Agglutination Test for Bang's Disease (pp. 26, 27), and A Study of the Occurrence of Discrepancies in the Results Obtained with the Rapid and the Test-Tube Agglutination Tests for the Diagnosis of Bang's Disease (p. 27), all by C. R. Donham and C. P. Fitch; Hypersensitiveness to Air-Borne Bee Allergen, by R. V. Ellis and H. G. Ahrens (pp. 31, 32); Paradoxical Terminology in Genetics, by F. B. Hutt (p. 35); and Is Water in Living Organisms Ordinary Water? by R. A. Gortner (p. 36).

Forty-third Annual Report [of New Mexico Station, 1932], F. GARCIA (*New Mexico Sta. Rpt. 1932*, pp. 85, figs. 9).—The experimental work not previously referred to is for the most part noted elsewhere in this issue.

Forty-fifth Annual Report of [Rhode Island Station, 1932], B. E. GILBERT (*Rhode Island Sta. Rpt. (1932)*, pp. 39-61).—The experimental work not previously referred to is for the most part noted elsewhere in this issue.

Dedication of Jenkins laboratory, October 11, 1932 (*Connecticut State Sta. Bul. 345* (1933), pp. 185-207, figs. 3).—The papers and proceedings at the dedication exercises (F.S.R., 68, p. 139) are here given.

Publications available for free distribution (*Idaho Sta. Circ. 69* (1932), pp. 4).—A list of the publications available as of December 1932.

Reports on the work of agricultural research institutes and on certain other agricultural investigations in the United Kingdom, 1930-1931 (*London: Govt., 1932*, pp. 377).—In this volume is presented the progress of agricultural research conducted during the year 1930-31 at research agencies in the United Kingdom. The research report includes soils; plant nutrition, physiology, and breeding; crop varieties and seeds; horticulture and glass-house crops; entomology and plant pathology; agricultural parasitology; animal pathology, nutrition, and breeding; dairying; agricultural economics; preservation and transport; agricultural engineering; local investigations at advisory centers; and various other investigations.

A list of papers published during the year is inserted at the end of each subdivision of the report. The appendix carries a list of names and addresses of research institutes and persons in charge of investigations at other research centers.

British and Irish writers on agriculture, compiled by W. F. PERKINS (*Lymington, Eng.: Chas. T. King, 1932*, 2. ed., pp. XI-193).—This is a bibliography of about 1,300 British and Irish writers on the agriculture of the United Kingdom from the earliest printed books through the year 1900. Appendixes list over 370 anonymous books during the same period.

NOTES

Colorado College.—Dr. Barton Orville Aylesworth, president from 1899 to 1900, as well as professor of political economy and logic, died in Denver July 1 at the age of 73 years. He was a native of Illinois and had been president of Drake University, pastor of the Central Church of Christ of Denver, and a national lecturer and organizer of the National American Woman's Suffrage Association.

Iowa College and Station.—Dr. A. G. Black, head of the department of agricultural economics, has been granted leave of absence to become acting corn-hog production chief of the Agricultural Adjustment Administration of the U.S. Department of Agriculture. In this new activity he will assist in the formulation of initial policies for applying the Agricultural Adjustment Act to corn and hog production and marketing problems.

Kansas College.—The honorary D.Sc. degree was conferred at the college at its recent commencement on Frank A. Waugh '91, head of the department of landscape architecture of the Massachusetts College.

Massachusetts College.—At the recent commencement the honorary D.Sc. degree was conferred upon Dr. Joseph B. Lindsey '83 (E.S.R., 68, p. 426), and Dr. Homer J. Wheeler '83, for many years director of the Rhode Island Station.

Montana College and Station.—The legislature reduced the station appropriations from \$118,800 to \$72,517 for the coming biennium. A request for detailed soil survey work was eliminated. This curtailment has resulted in the elimination from the station work of L. P. Reitz, assistant agronomist; D. M. Feese, assistant in the grain inspection laboratory; and Theodore T. Chaddock, laboratory assistant in veterinary research. M. L. Wilson, head of the agricultural economics work in the station and extension service, has been granted indefinite leave of absence to become wheat production administrator in the Agricultural Adjustment Administration of the U.S. Department of Agriculture. Louis Vinke, head of the department of animal husbandry in the college and station, has resigned, effective July 31, to engage in commercial work.

Nevada Station.—The station reports that even though the snow surveying project is suffering temporary loss of support through failure of State legislatures to make the usual appropriations, the expansion of this activity has continued. Local appreciation of its importance has been shown by the water users of the Humboldt Basin, who despite financial problems have authorized the continuance of the snow surveys in that basin at private expense. A Western Inter-State Snow Survey Conference was recently organized at the station, which is planning to publish the proceedings of the first meeting.

West Virginia Station.—Fred E. Brooks, associate entomologist in the fruit insect investigations of the U.S. Department of Agriculture, with which he had been connected since 1911, died at French Creek, March 9, at the age of 65 years. He was a native of the State and had served as agent in the station from 1903 to 1906 and as associate entomologist from 1907 to 1911.

New Journals.—*The Empire Journal of Experimental Agriculture* is being published quarterly by Humphrey Milford, Oxford University Press, Amen House, Warwick Square, London, E.C. 4, under the management of an editorial board headed by Sir John Russell of the Rothamsted Experimental Station. It is projected as a medium for the publication of original papers dealing particularly with problems relating to crops and animal husbandry

and the results of controlled experimental work in the field arising from fundamental scientific investigation. The initial number contains the following articles: The Breeding of Early-Ripening Varieties of Spring Wheat in Canada, by L. H. Newman (pp. 3-16); The Influence of the Nutritional State of the Sheep on Its Susceptibility to Infestation with the Stomach Worm, *Haemonchus contortus*, by A. H. H. Fraser and D. Robertson (pp. 17-21); Rothamsted Experiments on Residual Values of Leguminous Crops, by H. Nicol (pp. 22-32); Methods and Scope of Soil Surveys in Western Canada, by A. H. Joel (pp. 33-42); Grassland Management and Its Influence on the Sward—Part I, Factors Influencing the Growth of Pasture Plants, by M. G. Jones (pp. 43-57); The Development of Haymaking Machinery, by W. H. Cashmore and J. E. Newman (pp. 58-67); The Influence of Artificially Dried Grass in the Winter Ration of the Dairy Cow on the Colour and Vitamin A and D Contents of Butter, by S. J. Watson, J. C. Drummond, I. M. Heilbron, and R. A. Morton (pp. 68-81); The Relation of Soils to Grain-Growing in Kent in the Thirteenth Century, by R. A. Pelham (pp. 82-84); and Investigation of Soil Profiles from Cyprus—Part I, Profiles of Soils over Limestone and Serpentine, by A. Reifenberg and E. K. Ewbank (pp. 85-96).

Herbage Reviews is being published quarterly in conjunction with *Herbage Abstracts* by the Imperial Bureau of Plant Genetics, Aberystwyth, Wales. In addition to news notes, short articles, and a bibliography on lucerne pollination, breeding, and seed setting, the initial number contains the following original articles: Research on Forage Plants at the Agricultural Experiment Station in Bari, by E. Pantanelli (pp. 1-4); The Genus *Lespedeza* in Agriculture, by A. J. Pieters (pp. 4-7); Grass Seed Production and Gall Midges, by H. F. Barnes (pp. 7-9); and Theoretical and Practical Significance of Lyssenko's Research on the Vernalisation of Agricultural Plants, by F. Favorov (pp. 9-14).

Revue Vétérinaire Slave is being published by Józef Jankowski & Co., Zielna 20, Warszawa (Warsaw), as the official organ of the Union of Slavic Veterinarians. Its purpose is to present brief abstracts of original publications and bibliographical notices of veterinary publications of the countries represented in the union, Poland, Bulgaria, Czechoslovakia, and Yugoslavia. The initial number contains about 75 abstracts. Titles are for the most part given in the Slavic languages but with translations in German, French, or English. The abstracts are mainly in German or French, with some in English.

The forthcoming publication of an *Index Veterinarius* is announced by the Imperial Bureau of Animal Health of the Ministry of Agriculture and Fisheries of Great Britain, which is located at Weybridge, Surrey, England. The first number of this index, covering material indexed by the bureau during the first quarter of 1933, is to be issued during the present summer. An annual volume, made up of four quarterly numbers, each of about 400 pages and containing about 2,500 references, is contemplated.

Miscellaneous.—Following transfer by the South Carolina State Legislature on May 13 of the State Food Research Laboratory at Charleston to the State Medical College, the trustees of the college have announced that because of heavy reductions in the appropriations continuance of the laboratory will be impossible. For some years this work has been under the direction of Dr. R. E. Remington.

Press reports announce the discontinuance of the College of Agriculture of Syracuse University, organized in 1910. A statement from the university chancellor attributes this action to a desire to avoid duplicating in considerable measure the work of the New York State College of Agriculture at Cornell University.

EXPERIMENT STATION ~~RECORD~~

VOL. 69

SEPTEMBER 1933

No. 3

EDITORIAL

APPROPRIATIONS AVAILABLE TO THE FEDERAL DEPARTMENT OF AGRICULTURE

For many years it has been the custom in these columns to summarize briefly the current legislation making provision for the Federal Department of Agriculture. Normally this discussion is based on the agricultural appropriation act covering the new fiscal year. Under present conditions, however, the situation is much more complicated, and such estimates as now seem possible are dependent in large degree upon other legislation and subject to the possibility of later revision.

According to a statement recently issued by the Department, its cash withdrawals from the Treasury during the fiscal year ending June 30, 1934, will be limited to \$60,189,538. This amount is available for the regular work of the Department and for Federal aid to the States for experiment stations, extension work, and forestry, but does not include the very substantial allotments for roads, permanent construction under the various recovery acts, or the expenditures under the Agricultural Adjustment Act. It is comparable with appropriations aggregating \$81,879,556 for the previous fiscal year, and represents a reduction by the President under special powers conferred upon him by Congress of \$15,154,569 from the appropriations made by the Seventy-second Congress in an act approved March 3, 1933. It is a reduction of 37 percent as compared with the corresponding appropriations for the fiscal year 1932. The allotments for research in the two years are estimated at about \$17,000,000 and \$11,000,000, respectively, a reduction of 35 percent.

Of the total amount still available \$42,794,618 is allotted to what are termed the ordinary activities of the Department. The remainder includes \$9,839,322 for payments to the States for experiment stations and extension work and \$7,555,598 for anticipated deficiencies in fighting forest fires and similar items.

The allotments to the various bureaus and offices of the Department represent an aggregate decrease of \$15,834,507 from the previous year. About half of this amount is accounted for by the 15 percent reduction in all salaries which has been effective since April 1, 1933, and the remainder is expected to be absorbed mainly by additional furloughs without pay, nonfilling of vacancies, curtailment, suspension, or discontinuance of lines of work, and other economies.

The reductions have been apportioned among the bureaus and offices in varying degree. The Bureau of Animal Industry is allotted \$11,778,135, a reduction from \$15,324,947; the Forest Service \$7,645,559 as compared with \$10,780,924; and the Bureau of Agricultural Economics \$4,497,150, a reduction of \$2,152,691, mainly because of radical curtailments in the Market News Service. For the Bureau of Plant Industry \$3,728,195 is allotted, as compared with \$4,930,874 for the previous year. Other reductions include the Weather Bureau from \$4,164,038 to \$2,909,884; the Bureau of Plant Quarantine from \$2,490,125 to \$1,797,694; the Bureau of Entomology from \$2,471,700 to \$1,729,241; the Food and Drug Administration from \$1,716,167 to \$1,493,000; the Bureau of Chemistry and Soils from \$1,925,080 to \$1,470,305; the Extension Service from \$1,688,170 to \$1,189,267; the Office of the Secretary from \$1,206,547 to \$1,029,442; the Bureau of Biological Survey from \$1,756,177 to \$1,017,261; and the Office of Information, including the Department's printing funds, from \$1,335,800 to \$916,966. For the smaller units the reductions are for the Bureau of Dairy Industry from \$717,448 to \$545,000; the Bureau of Agricultural Engineering from \$618,690 to \$423,971; the Bureau of Home Economics from \$233,365 to \$169,338; the Grain Futures Administration from \$218,838 to \$166,639; and the Library from \$106,100 to \$88,901.

The Office of Experiment Stations is allotted \$198,670, an apparent reduction from \$294,294, but of the latter amount \$30,000 was provided for the liquidation of the Alaska, Guam, and the Virgin Islands Stations in 1932. The significant reduction is \$45,622, or slightly under 17 percent.

The item previously mentioned of \$9,839,322 for the payments to the States for experiment stations and extension work has been computed as a 25 percent reduction from the 1934 appropriations in conformity with the terms of an Executive order issued by the President on June 10, 1933. The quota payable on July 1, 1933, under these appropriations was, however, met in full, and on July 26 a further Executive order deferred the effective date for the enforcement of the previous order until March 21, 1934. This postponement affords 60 legislative days for consideration of the matter by Congress as proposed in a joint resolution passed by the Senate on June 15, 1933. Should subsequent installments for the year ultimately be made on the basis of the appropriation act, the experiment stations would receive \$4,381,000 and the extension services \$8,738,096. These are the full amounts authorized under the Hatch, Adams, and Purnell Acts, the various extension measures, and supplementary legislation extending the acts in whole or in part to the Territories and other possessions of the United States.

RECENT WORK IN AGRICULTURAL SCIENCE

AGRICULTURAL AND BIOLOGICAL CHEMISTRY

Colloid chemistry, theoretical and applied.—III, IV, **Technological applications**, edited by J. ALEXANDER (*New York: Chem. Cat. Co., 1931, vol. 3, pp. 655, figs. 164; 1932, vol. 4, pp. 734, figs. 116*).—Volumes 3 and 4 of this work (E.S.R., 55, p. 709; 60, p. 410) are designated the first and second series, respectively, of papers on technological applications.

Volume 3 contains 42 papers, among them the following: Cohesion and Adhesion, by J. W. McBain and J. Alexander (pp. 9-26); Some Practical Results of X-ray Researches on Colloids, by G. L. Clark (pp. 27-40); Wetting of Solids by Liquids, by F. E. Bartell (pp. 41-60); Spontaneous Dispersion of Small Liquid Particles, by N. Rashevsky (pp. 61-64); The Influence of Elasticity and Permeability on the Swelling of Two-Phase Systems, by K. von Terzaghi (pp. 65-88); On the Rubber-like and Liquid-Crystalline States of Matter, in Connection with the Classification of Crystals and Molecules According to Their Vectorial Fields, by P. P. von Weimarn (pp. 89-102); Surface and Catalysis, by E. F. Armstrong (pp. 103-106); Contact Catalysis, by H. S. Taylor (pp. 107-118); Adsorption by Silica Gel, Theory and Applications, by E. B. Miller (pp. 119-134); Colloid Factors in Water Supply, by W. D. Turner and D. D. Jackson (pp. 135-156); Crushing and Fine Grinding of Quartz, by L. Navias (pp. 157-178); Colloid Mills and Comminution Chemistry, by A. Chwala (pp. 179-188); Suspensoids and Their Electrical Precipitation, by W. W. Strong (pp. 189-206); The Super-Centrifuge in Industry, by E. M. James (pp. 207-214); Notes on Filtration, with Special Reference to Metafiltration, by J. A. Pickard (pp. 215-224); The Flotation Process, by G. H. Buchanan (pp. 225-238); Colloid Chemistry and Geology, by R. E. Liesegang (pp. 251-260); Colloidal Minerals, by C. Doelter (pp. 261-282); Some Colloidal Properties of Sodium Silicate Solutions, by W. Stericker (pp. 289-296); The Colloidal Nature and Properties of Cements and Mortars, by A. B. Searle (pp. 357-412); The Properties of Thin Films on Metals, by U. R. Evans (pp. 473-476); The Colloids and the Corrosion of Iron, by J. N. Friend (pp. 477-490); Soil Colloids, by J. di Gleria and F. Zucker (pp. 559-568); The Colloidal Chemistry of the Soil, by R. Bradfield (pp. 569-590); Rapid Colloidal and Mechanical Analysis of Soils, by G. J. Bouyoucos and M. M. McCool (pp. 591-596); and The Colloid Chemistry of Wheat, Wheat Flour, and Wheat Flour Products, by R. A. Gortner (pp. 597-626).

Volume 4 also contains 42 papers, among them Colloid Chemistry of Cellulose, by M. Samec (pp. 7-86); Colloid Chemistry of Wood and Wood-Formation, by H. Wislicenus (pp. 67-74); Cellulose Esters, by E. W. J. Mardles (pp. 87-100); Colloid Chemistry in the Sugar Industry, by R. T. Balch and H. S. Paine (pp. 137-162); Applied Colloidal Chemistry in Confectionery Manufacture, by S. Jordan (pp. 163-166); A Summary of the Colloid Chemistry of Starches, by M. Samec (pp. 167-186); Starch and Some of Its Derivatives, by V. G. Bloede (pp. 187-192); Sizing and Finishing of Textile Materials, by L.

A. Olney (pp. 193-196); The Process of Dyeing, by G. Georgievics (pp. 197-204); Dyeing, by W. Harrison (pp. 205-218); Theory of Dyeing, by W. D. Bancroft (pp. 219-234); Synthetic Resins, by H. L. Bender (pp. 351-362); Dispergation and Aggregation of Natural Silk in Aqueous Solutions of Neutral Salts, by P. P. von Weimarn (pp. 363-396); Technologically Useful Properties of Casein, by F. L. Browne (pp. 399-414); Notes on Colloidal Phenomena in Paint and Varnish Products, by H. A. Gardner (pp. 477-494); Colloidal Aspects of Paint and Varnish Removers, by N. Boehmer (pp. 495-498); Colloidal Aspects of Baking Chemistry, by C. N. Frey and Q. Landis (pp. 539-578); Butter and Margarine from the Standpoint of Colloid Chemistry, by W. Clayton (pp. 579-588); The Pectic Substances, by R. Johnstin and M. A. Griggs (pp. 601-616); Alkaline and Other Detergents, by H. G. Elledge (pp. 635-652); The Colloid Chemistry of Washing, by L. Zakarias (pp. 653-666); and Colloidal Aspects of Waste Treatment, by A. M. Buswell (pp. 669-695).

A carotene derivative giving with antimony trichloride an absorption band at 610-630 μ , M. VAN EEKELEN and A. EMMERIE (*Nature [London]*, 131 (1933), No. 3304, p. 275).—A carotene derivative has been prepared which gives the same absorption band in the antimony trichloride reaction as vitamin A, but is devoid of growth-promoting activity. The method consisted in boiling 150 mg of carotene for 15 minutes with a mixture of 100 cc of acetone and 1 cc of hydriodic acid (sp. gr. 1.7), cooling to room temperature, adding 150 cc of petroleum ether, and removing the acetone by washing with water. When the petroleum ether solution is shaken vigorously with strong sodium thiosulfate solution and treated with antimony trichloride in chloroform (with the addition of 1 drop of anhydrous acetic acid), a blue color develops with an absorption down to 640 μ . On adding to the petroleum ether solution 20 cc of 1 percent sulfuric acid and shaking with small quantities of a 1 percent sodium nitrite solution and testing from time to time with the antimony trichloride reagent, a strong absorption band at from 610 to 630 μ appears, maximum absorption being reached at a point at which the color of the petroleum ether solution has almost disappeared.

Physiological studies of the butyl-acetone group of bacteria.—I, Gelatinolysis, C. H. WERKMAN and G. L. STAHLY (*Iowa State Col. Jour. Sci.*, 7 (1933), No. 2, pp. 93-109, pl. 1, figs. 4).—For the testing of cultures of bacteria for their capacity to liquefy gelatin, the authors of this contribution from the Iowa Experiment Station found three methods—namely, the formation of white precipitate when acidified mercuric chloride solution was added to undecomposed gelatin, the use of a culture-tube viscometer, and the determination of the maximum temperature of gelation—to agree among themselves. Of the relative usefulness of two of these methods it is noted that "the modified mercury-protein precipitation method has given very satisfactory results in our hands and is simple and convenient. The use of the culture-tube viscometer is likewise to be recommended. This method gives excellent results and provides for the determination of the progress of gelatinolysis with time. For cultures growing at 37° C. over a period of 48 hours, no rejuvenation is necessary. Before using the culture-tube viscometer at incubation temperatures below 37°, it would be necessary to determine whether rejuvenation is required. Should rejuvenation be necessary at 50° for 10 to 20 minutes, it would, of course, prevent taking readings at intervals." Of the gelatin temperature method it is recorded that "it may be concluded that nonliquefying cultures do not change the maximum temperature of gelation during 3 days' growth at 37°."

The behavior, in these tests of 22 species and strains of the butyl-alcohol-acetone group of bacteria is recorded.

Direction of microbial lipase by copper soap formation, J. A. BERRY (*Jour. Bact.*, 25 (1933), No. 4, pp. 433, 434).—The author of this contribution from the U.S.D.A. Bureau of Plant Industry utilized copper soap formation as a test for lipatic activity by adding to each tube of standard nutrient agar 0.5 cc of a suitable oil or melted fat (for example, melted butter of good quality), sterilizing in the usual way, and pouring the well mixed medium at 45° C. into Petri dishes. The test itself consisted in the incubation for 48 hours at a suitable temperature of streak inoculations, the growth period being followed by the flooding of the plate with saturated aqueous copper sulfate, and carefully rinsing with water after 10 minutes. Bluish green streaks of the insoluble copper soap appearing on the plate indicate a lipolytic activity of the extent of which the intensity of the color was found to serve as a rough index. Cottonseed oil or soybean oil could be used in place of the butter.

"Among organisms giving positive tests are *Staphylococcus aureus*, *S. albus*, *Sarcina lutea*, *Pseudomonas fluorescens*, *Penicillium expansum*, and other molds. Among the negative organisms are *Escherichia coli*, *Bacillus subtilis*, *B. mycoides*, and yeasts generally."

Characteristics of highly active vitamin A, F. H. CARR and W. JEWELL (*Nature [London]*, 131 (1933), No. 3299, p. 92).—The authors announce briefly the preparation by the help of a high vacuum distillation technic of a much more active concentrate of vitamin A than hitherto prepared, as noted in papers by Karrer et al. (*E.S.R.*, 68, p. 151) and Heilbron et al. (*E.S.R.*, 68, p. 723). The fraction, boiling between 136° and 137° C., had an antimony trichloride blue value of 78,000 as compared with 65,000 reported by Heilbron et al. The spectographic figures were also high. Ultimate analysis gave values of C 83.5 percent and H 10.6 percent, which are in excellent agreement with the theoretical values of 83.9 and 10.5 percent, respectively, required for the formula $C_{40}H_{56}O$ suggested by Karrer. In rat feeding tests 0.0006 mg daily gave slightly better growth than 0.001 mg (one unit) of international standard carotene. This dosage also cured xerophthalmia.

Ultra-violet absorption spectrum and chemical structure of vitamin B₁, (*Nature [London]*, 130 (1932), No. 3290, pp. 773, 774, fig. 1).—This communication includes a brief report by F. F. Heyroth and J. R. Loofbrouow of studies of the absorption spectra of various vitamin B₁ concentrates and the comments upon this report by F. P. Bowden and C. P. Snow, whose earlier report on the photochemistry of the vitamins has been noted (*E.S.R.*, 67, p. 500).

The concentrates examined in the present investigation included four vitamin B₁ concentrates prepared in the authors' laboratory, three supplied by other workers, and three reported by Guha (*E.S.R.*, 66, p. 707) and by Windaus et al. (*E.S.R.*, 67, p. 101). With the exception of two relatively inactive concentrates with high absorption in the region of 2,600 Å, a good degree of correlation was found between the activity and the absorption in this region.

"The type of absorption thus attributed to vitamin B₁ resembles most closely, of the nitrogenous heterocyclic compounds which have thus far been investigated, the absorption of pyrimidine-ring-containing compounds, or of compounds of the type of ergothioneine. The absorption curve of the sulfur-containing Windaus preparation, the most active of those considered, is in fact very similar to that of uracil or other pyrimidines. The molecular extinction coefficient of the Windaus preparation at 2,600 Å, as calculated from the empirical formula of Windaus, is 8,225, and, as calculated from the formula of Van Veen, is 8,925. That of uracil at the same wave length is 9,500."

The antineuritic vitamin, II-VI [trans. title], A. G. VAN VEEN (*Rec. Trav. Chim. Pays-Bas*, 50 (1931), Nos. 2, pp. 200-220; 5, pp. 610-616; 51 (1932), No. 2,

pp. 265-272, 279-285).—In continuation of the investigation noted from a preliminary report (E.S.R., 65, p. 311), five papers are presented.

Paper 2 (pp. 200-207) deals with the Jansen and Donath method of concentrating vitamin B from rice polishings through the stage of adsorption by "acid clay" and liberation of the active material by barium hydroxide.

In the third paper (pp. 208-220), entitled *The Constituents of the Extract from Activated Acid Clay*, the results are reported of fractional precipitation of the extract from acid clay with silver nitrate and barium hydroxide at varying H-ion concentrations.

The fourth paper (pp. 610-616) is concerned with the purification of the silicotungstic acid fraction by successive treatments with aqueous platinum chloride, aqueous gold chloride, and alcoholic cadmium chloride and the use of aromatic acids and sulfonic chloride to remove the impurities. The final separation of the active material was as a crystalline hydrochloride with the same melting point and properties as that obtained by Jansen and Donath.

Paper 5 (pp. 265-272), entitled *The Empirical Formula of the Antineuritic Vitamin*, reports the analysis of the crystalline hydrochloride obtained in the previous study. An empirical formula of $(C_6H_{10}O_2N_2HCl)_x$ is proposed, but the possibility is suggested that the crystalline substance is not the vitamin itself but a provitamin which is converted into the vitamin in the animal body.

In paper 6 (pp. 279-283), entitled *The Properties of the Antineuritic Vitamin from Rice Bran*, the author summarizes the chemical properties of the crystalline hydrochloride.

The crystalline preparation of vitamin B from yeast and rice bran, I [trans. title], A. G. VAN VEEN (*Hoppe-Seyler's Ztschr. Physiol. Chem.*, 208 (1932), No. 1-3, pp. 125-128).—In this paper, which is the seventh in the series noted above, the author reports biological and chemical comparisons of samples of the crystalline vitamin B hydrochloride prepared by Windaus and associates from yeast (E.S.R., 67, p. 101) and his own crystals from rice bran. Both preparations had identical activity when tested on rice birds. The hydrochlorides, chloroaurates, and picolonates of both had identical melting points, but on analysis the author's preparation gave values corresponding most closely with an empirical formula of $C_{10}H_{10}O_2N_2S$ for the free base, a formula differing slightly from that of Windaus.

The sulfur is thought to be combined otherwise than in cystine or cysteine.

The antineuritic vitamin from rice bran.—VIII, The antineuritic vitamin from rice bran and polyneuritis in experimental animals [trans. title], A. G. VAN VEEN (*Meded. Dienst Volksgezondh. Nederland. Indië*, 21 (1932), No. 4, pp. 184-195).—In this continuation of the series noted above, tests are reported of the activity of crystalline preparations of vitamin B (B_1) for rice birds, pigeons, and rats and interpreted in terms of activated clay, the international standard for vitamin B (E.S.R., 66, p. 690). It is concluded that 100 units of the standard clay have the same activity as 0.4 mg of the crystalline vitamin. For protection against polyneuritis from 0.4 to 0.5 international unit is required for rice birds, from 2 to 3 units for pigeons, and from 1 to 2 units for young rats.

Potency of vitamin B_1 preparations, H. W. KINNERSLEY, J. R. P. O'BRIEN, and R. A. PETERS (*Nature [London]*, 130 (1932), No. 3290, p. 774).—Comparative pigeon tests (curative) are reported for crystalline specimens of vitamin B (B_1) prepared by the authors' method (E.S.R., 68, p. 725) and the crystals of Windaus et al. (E.S.R., 67, p. 101), with results showing that crystals prepared by the authors' technic were $1\frac{1}{4}$ times as potent as those of Windaus. It is concluded that the preparation of Windaus cannot be pure vitamin B.

Indophenol reducing capacity of lemon juice and its fractions in relation to vitamin C activity, S. S. ZILVA (*Nature [London]*, 131 (1933), No. 3306, p. 363).—A reply to the comments of Dann noted previously (E.S.R., 69, p. 169).

On the sulfur content of the hemoglobin of human blood [trans. title], Z. ASZÓDI (*Biochem. Ztschr.*, 252 (1932), No. 4-6, pp. 387-391).—The author determined the sulfur content of hemoglobin preparations made from the blood of 32 patients showing various conditions specified in the table of results submitted, and reached the conclusions (1) that the hemoglobin of human blood contains about 0.65 percent of sulfur, and (2) that the red blood corpuscles of human blood may contain hemoglobins of various sulfur contents.

Cataphoresis: An improved cylindrical cell, S. MATTSO (*Jour. Phys. Chem.*, 37 (1933), No. 2, pp. 223-227, fig. 1).—A new form of cataphoresis cell described in this contribution from the New Jersey Experiment Stations is a modification of the author's former design (E.S.R., 60, p. 410), and has as one of its important advantages over the former style of construction the much greater ease with which the cell may quickly and thoroughly be cleaned. The electrodes are prevented from interfering with the cleaning by being made in the form of cones sealed to the walls of exactly fitted conical expansions or electrode chambers at the ends of the tube. Further, this construction permitted the relatively large electrode area necessary to prevent the appearance of gas bubbles.

The paper contains also a brief discussion of some mathematical features of cataphoretic measurements.

The measurement of organic impurities in sands by means of a photo-electric cell, H. W. LEAVITT and W. S. EVANS (*Matne Technol. Expt. Sta. Bul.* 28 (1932), pp. 12, figs. 3).—The color intensity of dilute sodium hydroxide extracts of sand samples was measured in a simple, readily standardized photo-electric cell apparatus, replacing the usual ocular comparison with temporary or permanent color standards. The construction and manipulation of the device are given in detail. The new procedure gave a wide range of readings to cover plate colors from plate 0 to plate 4.5, very accurate readings, and almost perfect check readings. It was found not subject to any personal equation of the operator. The necessary apparatus could be installed in any laboratory at small expense, and the method gave a high correlation with the old field test so that accurate conversions can be made if desired.

A simple, inexpensive electron tube potentiometer for use with the glass electrode, L. D. GOODHUE, L. H. SCHWARTZ, and E. I. FULMER (*Iowa State Col. Jour. Sci.*, 7 (1933), No. 2, pp. 111-118, figs. 2).—A simplified circuit for an electron tube potentiometer for use with the glass electrode is described as composed of standard units which can readily be obtained at small cost. The equipment "makes use of the common vacuum tube UX 232, which is inexpensive and can be obtained at any radio supply shop. Circuits previously described in the literature generally involve the use of the more expensive types of vacuum tubes, complex circuits, and elaborate shielding. The equipment described can be used with almost any type of potentiometer and fairly sensitive galvanometer and can be made compact to form a portable unit. The structure and operation are so simple that the apparatus is suitable for routine laboratory use."

Electron tube potentiometer for the determination of redox potentials, C. H. WERKMAN, C. A. JOHNSON, and H. D. COILE (*Iowa State Col. Jour. Sci.*, 7 (1933), No. 2, pp. 163-175, pl. 1, figs. 7).—The authors describe three electron tube potentiometers found to be suitable for the determination of oxidation-reduction potentials in bacterial cultures, the apparatus using inexpensive elec-

tron tubes obtainable from radio dealers. "The apparatus has been in use for several months and gives consistent and reproducible readings."

Soil testing: A practical system of soil diagnosis, C. H. SPURWAY (*Mightigan Sta. Tech. Bul. 132 (1933), pp. 16, pls. 8*).—The bulletin gives working directions for the preparation and use of reagents for semiquantitative tests of soil extracts for nitrates, phosphates, potassium, calcium, carbonates, ammonia, nitrites, magnesium, iron, aluminum, manganese, sulfates, chlorides, and sodium, prescribing as a general extracting reagent a solution of one part of pure acetic acid in three parts of distilled water. Color charts included in the bulletin are to be used for classifying the results into the four indications as blank, low, medium, and high. For the white precipitates obtained in the chloride, sulfate, and calcium tests, the method is nephelometric, the shell vial containing the test mixture being placed upon a square of a standard deep red on the lighter color seen through the column of white suspension matched to squares of shades lighter than that of the full color, to which are attached the semiquantitative grades above noted, together with the approximate indications of the parts per million and pounds per acre 6 in. of soil, as is also done in the case of strictly colorimetric tests. In some of the tests the grades low or medium are subdivided into two indications numerically evaluated into parts per million and pounds per acre, and in some instances the descriptive discussions are omitted and only the numerical approximations given.

Rapid chemical methods for the estimation of the capacity of the soil to supply phosphoric acid to plants, G. S. FRAPS and J. F. FUDGE (*Jour. Amer. Soc. Agron., 25 (1933), No. 3, pp. 217-230*).—At the Texas Experiment Station chemical methods for estimating the capacity of the soil to supply phosphoric acid, consisting of two laboratory and two field methods, were compared with a new rapid colorimetric method devised by the authors, with the regular volumetric method using 0.2 N nitric acid, and with the results of pot experiments with 146 soils. The Hi-lo-fosphate field method of Bray (*E.S.R., 62, p. 13*) gave erratic results on the same soil at different times and was not reliable. The colorimetric citric acid method was slow and exacting and tended to give erratic results. The other methods tested were found to be erratic to a certain extent, but gave satisfactory results when properly controlled and checked and were rapid in operation. Results obtained by the several methods for most of the soils agreed quite well, indicating that the same phosphates were being brought into solution. The colorimetric Truog method (*E.S.R., 64, p. 312*) did not remove as much phosphoric acid from soils high in soluble phosphoric acid as did the two 0.2 N nitric acid methods and the colorimetric citric acid method. Usually in such cases, the Truog method was in best agreement with the pot experiments.

Results obtained by the 0.2 N nitric acid methods (regular and colorimetric) and the colorimetric Truog method agreed quite well with the results of the pot experiments as measured by the phosphoric acid removed by crops. "The relation of the colorimetric citric acid method to the results of the pot experiments was regular but not as close as with the above methods. The Truog-LaMotte method was fairly closely related to the results of the pot experiments on soils which gave low amounts of phosphoric acid to the crops, after which the relations were irregular. The Truog-LaMotte method seems to be much more reliable for field work than the Hi-lo-fosphate method. Extreme care must be taken at all times with all of the colorimetric methods to prevent erroneous results due to impurities in the reagents or other causes of error."

Comparison of methods for estimating available phosphorus in alkaline calcareous soils, R. D. HOCKENSMITH, R. GARDNER, and J. GOODWIN (*Colorado*

Sta. Tech. Bul. 2 (1933), pp. 24).—The Winogradsky method in the special case of calcareous alkaline soils gave, of 67 fields which did not respond to phosphate fertilizer, indications ranging from no visible growth of *Azotobacter* (3 percent of the samples) through the very deficient (25.4 percent), moderately deficient (28.3 percent), and slightly deficient (35.8 percent) to sufficient phosphate in 7.5 percent of the cases examined. Of 21 soils known to respond strongly to phosphate treatment, the *Azotobacter* test indicated 42.9 percent to be very deficient, 33.3 percent to be moderately deficient, 14.3 percent to be slightly deficient, 0 percent to be sufficient; and 9.5 percent gave no visible growth of *Azotobacter* colonies.

With the Truog method (E.S.R., 64, p. 312), the agreement with field trials for the "sufficient" soils was 73.9 percent, while for the soils which gave a great response in the field the agreement was 78.9 percent. The Dahlberg-Brown method (E.S.R., 67, p. 652) gave an agreement with the "sufficient" soils of 84.6 percent, while for the soils which gave a great response the agreement was 63.2 percent. The potassium carbonate method of Das (E.S.R., 64, p. 115) gave an agreement with the "sufficient" soils of 90 percent, while for the soils which gave a great response in the field, the agreement was 90.5 percent. "If, however, the data are calculated in a different way and the soils which gave a slight response are included with those which gave a great response, the agreement for the deficient soils drops from 90.5 percent to 73.1 percent."

Of the methods studied, the potassium carbonate method appeared to give the highest agreement with field results. "It seems probable that no chemical method for estimating the availability of soil phosphorus can imitate exactly the power which plants have for securing available phosphorus. The data show, however, that there is a fairly close relationship between the amount of phosphorus soluble in certain solvents and the amount which is available to plants. An alkaline solvent appears to be more satisfactory for alkaline calcareous soils than an acid extractant. The results . . . indicate that even though a laboratory test shows the soil to be deficient in available phosphorus, a field trial should be strongly recommended before a large quantity of fertilizer is purchased. A tentative procedure for the potassium carbonate method is given."

Colorimetric methods for the determination of readily available phosphorus in soils, C. O. ROST and R. M. PINCKNEY (*Jour. Amer. Soc. Agron.*, 24 (1932), No. 5, pp. 377-395).—The authors of this contribution from the Minnesota Experiment Station compared the Truog method (E.S.R., 64, p. 312), the Bray method (E.S.R., 62, p. 13), and a commercial adaptation of Truog's application of the Denigès reaction (E.S.R., 44, p. 611), among themselves and with the actual field responses of the soils examined.

The results given by the three methods showed a good agreement among themselves, indicating that in 9 of the 10 fields the readily available phosphate was rather low. The least concentration appeared in the surface soil, the greatest at a depth of 20 in. Of the comparison with field trial results it is stated that "with the Illinois test, 69 percent of the plats testing low and doubtful responded to phosphate, while 67 percent of those testing medium and 27 percent of those testing high also responded. Using the surface soil only, the percentage of responsive plats testing low was increased slightly, but for those testing doubtful, medium, and high it was decreased. When tested by the Wisconsin method, plats carrying 25 lb. or less per acre of readily available phosphorus at the surface responded to superphosphate in 69 percent of the cases and in 73 percent of the cases of those carrying between 26 and

50 lb. Nine of the 10 plats carrying more than 50 lb. failed to respond. The results secured with the La Motte-Truog test were not materially different from those secured with the Wisconsin method. The percentage of plats responding to superphosphate and carrying 50 lb. or less of available phosphorus was slightly lower, while for those carrying more than 50 lb. it was approximately the same. Using tests of surface samples only, predictions of phosphate deficiencies would be about as reliable as when subsoil samples were included. This would apply to all three methods, but especially to the Wisconsin and La Motte-Truog methods."

Standard methods for the examination of water and sewage, A. WOLMAN, M. PIRNIE, and H. E. JORDAN (*New York: Amer. Pub. Health Assoc., 1933, 7. ed., pp. XXI+180, fig. 1*).—The editors note the development of numerous new methods and modifications of methods since the appearance of the sixth edition (E.S.R., 55, p. 410), and they have adjudged some of these newer procedures as standardized sufficiently to justify their inclusion in the present edition. Also some procedures included in the previous edition have been discontinued in the present revision.

An iodometric micro method for the determination of chlorides [trans. title], N. BEREND (*Biochem. Ztschr., 252 (1932), No. 4-6, pp. 362-365*).—The solubility of silver chloride was reduced from 0.0134 mg in the 10 cc of solution in which the determination was carried out to less than 0.001 mg by working in dilute nitric acid solution containing 20 percent by volume of alcohol. Excess of a standard solution of silver nitrate was added, and, silver iodate having been shown also to be quantitatively insoluble in dilute nitric acid in the presence of 20 percent by volume of alcohol, the excess silver nitrate was determined by adding standard potassium iodate and titrating the iodate content of the filtrate, in the presence of potassium iodide sufficient for complete reaction with all of the iodate, with standard sodium thiosulfate solution. Since each atom of chlorine originally present results in the setting free of six atoms of iodine in the final reaction, the claim is advanced that the procedure is six times as sensitive as that of Volhard.

Full detail is given. The silver nitrate and sodium thiosulfate solutions used were 0.01 N, the iodate solution 0.06 N.

A convenient method for the determination of very small quantities of bromides in the presence of a large excess of chlorides [trans. title], F. HÄFTNER (*Hoppe-Seyler's Ztschr. Physiol. Chem., 214 (1933), No. 3-4, pp. 179-183, fig. 1*).—The author, finding that the action of potassium permanganate is likely to extend to the chloride as well as the bromide in a mixture of the two, and that even an hour of aeration does not necessarily carry over quantitatively all of the bromine into the absorption solution, was able to obtain better results by working with a rather weakly acid solution, adding manganese sulfate, setting free the bromine in a strong solution of a salt (preferably sodium sulfate), and, near the end of the process, setting free in the reaction mixture itself any such indifferent gas as, for example, carbon dioxide. Details of a procedure based upon these principles and of an apparatus adapted to the convenient working of the method are given.

A new and simplified colorimeter especially designed for the colorimetric estimation of manganese by the periodate method, G. F. SMITH and V. R. SULLIVAN (*Jour. Chem. Ed., 9 (1932), No. 8, pp. 1461-1471, figs. 6*).—The special feature of the instrument described in this contribution from the University of Illinois consists in the use of outlet stopcocks at the bases of the tubes as a means of adjusting the depth of liquid column through which the light

passes to the comparator eyepiece. The last-named part of the apparatus is also to some extent simplified. The color match having been obtained as above indicated, the heights of the two columns are read from millimeter divisions on the tubes. Full details of the construction, operation, and testing of the device are given, together with photographs and drawings.

A new volumetric determination of sodium in blood serum [trans. title], S. RUSZNYÁK and E. HATZ (*Biochem. Ztschr.*, 252 (1932), No. 4-6, pp. 414-419).—The sodium was precipitated by adding Kolthoff's reagent (E.S.R., 58, p. 608) in known excess, and after one half hour, during which time the precipitation was found to be completed, filtering off the sodium zinc uranyl acetate, adding a known excess of a standard solution of disodium hydrogen phosphate, and finally titrating the excess phosphate with standard uranyl acetate solution, cochineal as indicator. Detailed information with respect to (1) preparation of reagents, (2) deproteination of the sera, (3) removal of the phosphate, and (4) the precipitation of the sodium, the determination of the excess of the precipitant, and the calculation of the result is given.

The determination of thymonucleic acid by means of fuchsine sulfurous acid [trans. title], T. CASPERSSON (*Biochem. Ztschr.*, 253 (1932), No. 1-3, pp. 97-111, figs. 5).—Thymonucleic acid was found quantitatively determinable by the application of the fuchsine sulfurous acid reaction after acid hydrolysis. The effects of various factors and experimental conditions upon the hydrolysis and the color development were determined, and the optimum conditions are given. By means of an analysis of the hydrolyzed and color development curves it was ascertained that the reaction proceeds in two stages, and that further increases in color intensity beyond the color obtained under the conditions here given as optimum are not to be expected.

For best results the hydrolysis should be carried out at pH 2.3 and at a temperature of 100° C., and should be continued for from 3 to 4 hours. The color readings should be made after from 3 to 6 hours. The pH value during color development should, for maximum intensity, be from 2.3 to 2.6, since at higher pH values (about pH 3) a coloration of the reagent itself appears. The sample should contain from 0.5 to 10 mg of thymonucleic acid, but quantities as small as 0.1 mg could be determined. More than 10 mg necessitated increasing quantities of reagents and thereby introduced certain inconveniences.

On the microanalytical determination of picrolonic acid with the aid of acridine [trans. title], H. SCHIEDEWITZ (*Hoppe-Seyler's Ztschr. Physiol. Chem.*, 214 (1933), No. 3-4, pp. 177, 178).—The author notes the comparatively slight difference in elementary composition between picrolonic acid and most of the biochemically important bases for the identification of which the acid is used, with the concomitant difficulty in distinguishing between mono- and dipicrolonates; and further points out that although bromopicrolonic acid permits the desired sharpness of distinction between mono- and di-salts, the brominated acid is difficult to obtain in quantities sufficient for preparation work. For these reasons he proposes to dissolve from about 6 to about 12 mg of the picrolonate in question with the help of 1 cc of dilute hydrochloric acid in 20 cc of hot water, and to precipitate acridine picrolonate by adding 15 cc of a 0.3 percent acridine solution acidified with hydrochloric acid, the voluminous precipitate of acridine picrolonate being filtered off by means of a micro filter, washed with 40 cc of water, dried for 1.5 hours at from 120° to 130° C., and weighed. Satisfactory figures for the picrolonic acid content of 9 salts of biochemically important bases are shown.

AGRICULTURAL METEOROLOGY

Report of the Chief of the Weather Bureau, 1931-32 (U.S. Dept. Agr., Weather Bur. Rpt. 1932, pp. IV+129, pls. 4).—This report follows the plan of previous years except that the usual account of administrative activities and some tabular matter are omitted. It contains a general summary of the weather conditions for each month of 1931, including tornadoes, hail, losses from windstorms, sunshine, and evaporation, and the usual monthly and annual meteorological summaries.

Monthly Weather Review, [January-February 1933] (U.S. Mo. Weather Rev., 61 (1933), Nos. 1, pp. 32, pls. 11, figs. 10; 2, pp. 33-59, pls. 9, figs. 6).—In addition to the usual detailed summaries of climatological data, solar and aerological observations, observations on weather on the Atlantic and Pacific Oceans and on rivers and floods, and bibliographical and other information, these numbers contain the following contributions:

No. 1.—Solar Activity and Radio Reception, by H. T. Stetson (pp. 1-3); The Magnitude of the Error in Measurements of the Solar Radiation Received on a Horizontal Surface Arising from the Assumption that the Ratio between Radiant Energy Received and Electrical Energy Recorded is a Constant, by H. H. Kimball and I. F. Hand (p. 4); Certain Flood-Flow Phenomena of Iowa Rivers, by F. A. Nagler (pp. 5-7); The Technical Use that Engineers Make of United States Weather Bureau Observations, by C. H. Lee (pp. 7-10); Florida Hurricanes, by R. W. Gray (pp. 11-13); Lake Okeechobee and Safety from Tropical Storms, by A. J. Mitchell (pp. 13-15); The Relative Distribution of Early and Late Seasonal Rainfall in Southern California, by C. C. Conroy (pp. 15, 16); Severe Sand Storm in Eastern Wyoming, January 18, 1933, by F. L. Disterdick (pp. 16, 17); Unusual Lunar Halos (p. 17); The Dust Storm of January 22, 1933, over Sections of Illinois, Indiana, and Michigan, by C. G. Andrus (p. 17); and Solar Halo, December 14, 1932, at Moorhead, Minn. (p. 17).

No. 2.—Some Additional Facts about the Climate of Death Valley, Calif., by E. E. Eklund (pp. 33-35); Tides and Coastal Currents Developed by Tropical Cyclones, by I. M. Cline (pp. 36-38); A Brief Study of Oregon Temperatures, by E. L. Wells (pp. 38-40) (see p. 333); The Summer Nighttime Clouds of the Santa Clara Valley, Calif., by E. H. Bowle (pp. 40, 41); Some Aspects of Free-air Winds in the Far West, by T. R. Reed (pp. 42, 43); The Relation of June Temperature to the Maturing of Corn in Iowa, by C. D. Reed (pp. 43, 44) (see p. 333); Raininess Charts of the United States, by E. R. Miller (pp. 44, 45) (see below); Organization of the Meteorological and Aerological Services Relative to Aviation in Chile, by J. B. Navarrete (pp. 45, 46); and Aeronautical Meteorology in Germany, by E. R. Miller (p. 46).

Meteorological observations, [March-April 1933], C. I. GUNNESS and H. JENKINS (Massachusetts Sta. Met. Ser. Buls. 531-532 (1933), pp. 4 each).—The usual summaries are given of observations at Amherst, Mass., with brief notes on the more significant features of the weather of each month.

Raininess charts of the United States, E. R. MILLER (U.S. Mo. Weather Rev., 61 (1933), No. 2, pp. 44, 45, figs. 5).—The average raininess (number of days on which 0.0 in. or more of rain or melted snow falls) of the United States for the four seasons and for the year is shown in five charts. These show that "the number of rainy days is relatively greater in the Northeastern States than in the Southern. Hence the gradient of raininess from the Gulf States to the Lake region is somewhat steeper than the gradient of rainfall. The annual march of raininess varies from the interior toward the oceans. In the interior the raininess is smallest in winter, but is then largest on the Pacific slope. The North Atlantic States have relatively uniform raininess

throughout the year, but in the Gulf States winter and spring exceed summer and autumn." It is noted that raininess is more uniformly distributed than rainfall.

The relation of June temperature to the maturing of corn in Iowa, C. D. REED (*U.S. Mo. Weather Rev.*, 61 (1933), No. 2, pp. 43, 44).—Data are briefly presented to show that "the extent of autumn frost damage in Iowa is largely determined by the mean temperature of the previous June. . . . All of the outstanding years of frost damage had a June mean temperature below 67°."

A brief study of Oregon temperatures, E. L. WELLS (*U.S. Mo. Weather Rev.*, 61 (1933), No. 2, pp. 38-40).—It is stated that, considering only places where reliable records have been kept, the normal annual temperature of Oregon ranges from about 56° F. in the lower Snake River Canyon, in the extreme northeast, to about 38° in the high Cascade Mountains. The range in normal minimum temperatures for January is from 12° to 40°. Attention is called to the important part that latitude, altitude, nearness to the ocean, and local topography play in control of temperature in the State, and it is pointed out that high summer temperatures in the interior are often attended by low temperatures on the coast.

"It is difficult to determine the length of the growing season in the colder parts of Oregon, for over those regions agriculture is mostly confined to the growing of the hardier crops; moreover, in regions where the nights are so uniformly cool even the less hardy crops seem to develop a degree of resistance to frost. The records of killing frost show that over most of the region west of the Cascades the length of the growing season is more than 150 days, reaching 250 days on the coast. In the principal agricultural districts east of the Cascades it is between 100 and 200 days. Some of the high plateau districts have less than 50 days, and there are regions where frost may occur in any month of the year. However, even in these regions considerable areas are devoted to agriculture, and even some potatoes and garden vegetables are grown."

It is stated that "there is very little in the records . . . to indicate a progressive change in temperature."

SOILS—FERTILIZERS

[Soil Survey Reports, 1928 Series] (*U.S. Dept. Agr., Bur. Chem. and Soils [Soil Survey Rpts.], Ser. 1928, Nos. 28, pp. 46, pls. 3, fig. 1, maps 2; 29, pp. 60, pl. 1, fig. 1, maps 2*).—These two surveys were made with the respective cooperation of the New York Cornell and California Experiment Stations.

No. 28. *Soil survey of Suffolk and Nassau Counties, New York*, C. Lounsbury et al.—Suffolk and Nassau Counties cover nearly seven eighths of Long Island, possessing a combined area of 1,194 sq. miles (about 764,000 acres), the lands included consisting in general of two longitudinal moraines with two outwash plains, the one between two ridges and the other forming a south-shore belt.

The present survey places 22 types in 11 series, including Sassafras loam as amounting to 15.1 percent of the total area examined; Sassafras sandy loam, 12.4 percent; Dukes loamy sand, 12.1 percent; and Haven loam, 10.3 percent; with 4.9 percent of tidal marsh and small areas of 6 miscellaneous materials.

No. 29. *Soil survey of the San Luis Obispo area, California*, E. J. Carpenter and R. E. Storie.—The San Luis Obispo area occupies 469,760 acres, for the most part included in San Luis Obispo County and a small portion of the southern end of Santa Barbara County. Physiographic features include coastal terraces, parts of the Santa Lucia Mountains, and a foothills region.

The area includes 60.3 percent of rough mountainous lands and 8 percent of rough broken and stony land, coastal beach and dune sand, tidal marsh, and river wash. The agricultural lands are classified as 18 series inclusive of 30 types, of which Arnold sandy loam, covering 5.8 percent of the total area, is the most extensive.

[Soil Survey Reports, 1930 Series] (U.S. Dept. Agr., Bur. Chem. and Soils [Soil Survey Rpts.], Ser. 1930, Nos. 1, pp. 17, pls. 2, fig. 1, map 1; 2, pp. 24, fig. 1, map 1; 3, pp. 24, fig. 1, map 1).—The reports here noted deal with surveys made with the cooperation, respectively, of the New Mexico Experiment Station, the Iowa Experiment Station, and the Maryland Geological Survey and the Maryland Experiment Station.

No. 1. *Soil survey of the Fort Sumner area, New Mexico*, A. T. Sweet and E. N. Poulson.—The Fort Sumner area comprises 79,360 acres, forming a part of De Baca County in east-central New Mexico, and in surface relief presenting the features of a nearly smooth plain with drainage through the Pecos River.

The 14 soil types identified are classified as 3 series. Springer fine sandy loam, with the inclusion of a rolling phase, occupies 51.5 percent of the total area surveyed, and Springer loamy fine sand covers a further 15 percent. The unclassified material was found to consist of 1.5 percent of river wash. Alkali and pH determinations are included.

No. 2. *Soil survey of Calhoun County, Iowa*, W. E. Tharp et al.—Calhoun County, northwestern Iowa, possesses an area of 363,520 acres, of which the surface relief is that of an uneven plain having a combination of artificial and natural drainage adequate throughout the area of the county.

The survey reveals 18 types in 12 series. The most extensive type listed is Webster silty clay loam, found to cover a total of 39.1 percent of the area of the county, with 34.7 percent of Clarion loam and 18 percent of Webster loam. The only unclassified material found was 1.2 percent of muck.

No. 3. *Soil survey of Kent County, Maryland*, H. B. Winant and J. P. Bewley.—Kent County, northeastern Maryland, is an area of 180,480 acres, flat to rolling in surface, and draining to the Sassafras and Chester Rivers and Chesapeake Bay.

Of the 4 series and 12 types identified Sassafras silt loam was found to occupy 43.8 percent of the total area surveyed, with 16.6 percent of Keyport silt loam and 8.2 percent of unclassified coastal beach, meadow, and tidal marsh.

The genesis and development of two profiles of a drift soil in the northeast of Scotland, A. B. STEWART (*Jour. Agr. Sci. [England]*, 23 (1933), No. 1, pp. 73–96, figs. 2).—Of the two soil profiles upon which report is made in the present paper, one was in uncultivated land, the other in an adjoining cultivated soil derived from parent material of the same geological origin.

The first of the two soils was found to belong to the class of podsolized soils, but was shown to contain large reserves of unweathered material. Iron was "the only constituent which is present mainly in the 'HCl-soluble' condition." Further, "there is a tendency for certain of the bases, especially lime, to be retained in the surface vegetational layer A. There is more evidence of the leaching of Na and Mg than of Ca and K. Some organic material has also been carried down into the lower layers, but leaching generally has not proceeded to any great extent. The H-ion concentration diminishes with depth as in a typical podsol, and the relative proportions and distribution of the replaceable cations Ca, Mg, K, and Na, when these alone are considered, are in agreement with the results generally found in acid soils. . . . The external factors, climate and vegetation, appear to have determined the direction of

weathering—towards a soil of the podsolized type—but the unweathered material in the soil seems to be presenting the rapid formation of a podsol. The soil appears to be 'young' in the geological sense."

Of the cultivated area of the same soil it is recorded, in part, that "cultivation has increased the amount of weathered or easily soluble constituents in the soil and has prevented leaching to a considerable extent. . . . There is less evidence of podsolization than there is in the virgin profile. The organic material is concentrated mainly in the upper layer; there has been little leaching of the cations Ca and K, and only comparatively little leaching of Mg and Na from the surface soil. The soil is less acid than the virgin soil, and, except as compared with the A₁ layer in the virgin profile, there is a higher content in replaceable bases in this profile from cultivated land." The relative proportions and distribution of the replaceable cations Ca, Mg, K, and Na were found to agree with the results generally found in acid soils.

"Assuming that this profile would have been very similar to the virgin profile had it not been cultivated, cultivation may be regarded as having brought about a 'regradation' of the profile to a less podsolized type—a type bearing some resemblance to a brown earth."

Soil formation in southern Nigeria (the "Ilepa" profile), H. C. DOYNE and W. A. WATSON (*Jour. Agr. Sci. [England]*, 23 (1933), No. 2, pp. 208-215).—The typical profile of southwestern Nigeria, formed over acid igneous rocks under alternating conditions of percolation and evaporation, is described, the profile being (1) brown sandy soil, (2) concretion layer, (3) red clay, (4) mottled red and white clay, (5) whitish clay, (6) rotting rock. Acidity was found to increase with depth. Analyses of the concretion layer showed it to consist chiefly of silica (quartz) and ferric oxide, with occasionally some manganese. Alumina did not occur extensively.

On the basis of the mobility of the iron and soluble salts throughout the profile, "It is suggested that the profile is developed by a rise of an iron sol which is deposited on a layer of quartz to form the concretions. The Yoruba name 'Ilepa' has been adopted by the authors for describing such a profile."

Some notes on the soils of the Trans Nzola, with suggestions for the carrying out of simple field tests for their economic lime requirements, G. H. G. JONES (*Kenya Dept. Agr. Bul.* 8 (1932), pp. 11).—The bulletin gives a condensed description of the light reddish soils of the Trans Nzola, the statements being based upon about 100 observations of soil profiles, surface observation covering some 10,000 acres, simple tests for plant nutrients, etc. The bulletin takes up such topics as topography, geological origin, and mode of soil formation; the lime status of the Trans Nzola soils; the meaning of soil pH value; liming as a farm practice in the Trans Nzola; making the field test; and the phosphate status of the Trans Nzola soils. An appendix adds a tabulated statement of pH values and estimates of available phosphoric oxide content.

Proceedings of a conference of East African soil chemists held at the Agricultural Research Station, Amani, Tanganyika Territory, May 21st-26th, 1932 (*Tech. Confs. East African Dependencies, Nairobi, 1932, pp. 25.*)—The report contains discussions of the soil map of East Africa; of soil classification and nomenclature for East Africa; of analytical methods, including mechanical analysis, organic carbon, exchangeable bases, pH methods, sodium estimation, nitrogen, the thiocyanate test, the separation and analysis of the clay fraction, physical determinations, mineralogical determinations on sand fractions and rocks, and color; of soil problems involved in shifting cultivation; of a deficiency disease ("yellows") of tea in Nyasaland; and of termites as

agents in soil-forming processes. Of two appendixes the first concerns an exhibit of soil profiles, the second being a memorandum on soil description and sampling for use in East Africa.

The colonization of the Katmai ash, a new and inorganic "soil", R. F. GREGG (*Amer. Jour. Bot.*, 20 (1933), No. 2, pp. 92-113, figs. 5).—Further detail is added to the observations already reported upon (E.S.R., 68, p. 738) with respect to the appearance of certain liverworts as vegetative pioneers on volcanic ash ejected by the Katmai volcano in 1912, the ash being devoid of organic matter and practically nitrogen free (nitrates none, total nitrogen from 15 to 42.6 p.p.m.) when covered by a vigorous growth of the liverworts in 1930. The two more important species identified were the minute forms *Lophozia bicrenata* and *Cephaloxiella byssacea*. The last named appeared the more abundant form.

The paper discusses the results of the earlier Katmai expeditions; revegetation of other volcanic areas; liverworts as the pioneers on pure ash; physical and chemical conditions of the liverwort habitat; algae as indicators of available nitrogen; contaminations of the liverwort layer; possibility of symbiotic relations; liverworts unable to draw nourishment from a distance; liverworts on substrata other than the ash; and relations of the liverworts to succeeding plants.

A study of the exchangeable bases of some East Anglian soils derived from the Jurassic and Cretaceous sediments, with special reference to their marine origin, M. L. M. SALGADO (*Jour. Agr. Sci. [England]*, 23 (1933), No 1, pp. 18-30).—The results of an investigation of the exchangeable bases of some East Anglian soils derived from the Oxford, Ampthill, Kimeridge, and Gault formations of the Jurassic and Cretaceous ages are recorded. "As they were formed under the sea the original sediments contained sodium-clays, but on the return of terrestrial and fresh-water conditions the character of the deposits was completely changed and they now contain only traces of exchangeable sodium."

In the unweathered clay, represented by the 18 to 42 in. layer, exchangeable calcium formed only 75 percent of the total, magnesium 20 percent. As a result of leaching and weathering the magnesium on the surface is replaced by calcium which in the top 18 in. forms 85 percent, with the magnesium only 10 percent. "Thus the surface and deeper soils are distinguished by characteristic calcium:magnesium ratios." The ratio of divalent:monovalent bases was the same in the weathered top 18 in. and the lower layers. Samples of Oxford and Kimeridge clays obtained from deep brick pits showed in some cases quantities of exchangeable sodium larger than those of the surface layers, but there was still not enough to characterize them as sodium clays.

"The results prove that the poor tilth and difficulty in working Oxford, Gault, and similar soils is not due to the presence of sodium clays, . . . but is merely a natural result of the large amounts of clay and fine silt present in these soils."

Cohesion and viscosity of clays, E. G. RICHARDSON (*Jour. Agr. Sci. [England]*, 23 (1933), No 2, pp. 176-184, figs. 5).—The author describes the principles and operation of a hot-wire viscosimeter constructed on the concentric cylinder principle and adapted to the direct measurement of velocity gradients; a second type of concentric cylinder apparatus in which the inner cylinder was suspended by a wire from a torsion head, of which the purpose was "to obtain measurements of the more conventional type connecting the velocity of the outer cylinder with the torque exerted on the inner"; and some measurements of the properties of clay pastes obtained by the use of these devices.

He distinguishes "four types of liquid, classifying them according to their behavior under stress: (1) Normal liquids. Torque/rate of shear=constant. (2) Suspensions, including emulsions. Torque/rate of shear continually diminishing as the latter is increased. (3) Pastes. Flow in three stages as stress is increased: (a) Rigid resistance, (b) quasi-solid friction, (c) suspended flow. . . (4) Gels. Elastic resistance to small stresses; behavior to large stresses the same as (3)."

The significance of certain "single value" soil constants, E. W. RUSSELL (*Jour. Agr. Sci. [England]*, 23 (1933), No. 2, pp. 261-310).—As a result of a detailed statistical analysis of the physical property, data available from certain Natal soils which were studied, the base exchange capacity of the soil, as measured by the Schofield potassium phosphate buffer method, appeared of predominant importance for predicting several of such soil properties, as, for example, the sticky point and the moisture content at 50 percent relative humidity; whereas the clay content, on the other hand, seemed to be of minor importance in predicting these soil properties. Further, "the information from the data supplied by the Keen-Raczkowski box indicates that w , the weight of water held per gram of soil in the box, is very closely correlated with the base exchange capacity of the soil, while the swelling and pore-space parameters are more complex. The swelling v seems to be dependent on the base exchange capacity of the soil and a term probably representing the structure of the soil, while the pore space p seems to be dependent on the clay content and a soil structure term. By choosing an appropriate definition of the pore space, practically all the structure information given by the swelling parameters is contained in it.

"The xylene equivalent measures a property of the soil that is independent of the organic matter present, and can be almost completely predicted from parameters determined on the soil after it has been boiled with hydrogen peroxide. It is more completely determined than any other variate by the amount of clay and silt in the soil, though this prediction is not strikingly good. The moisture equivalent can be predicted with great accuracy from the xylene equivalent and the base exchange capacity of the soil. The amount of imbibitional water in the soil, as determined from the moisture equivalent and the xylene equivalent, is of only limited value as a prediction variate. The two primary variates are always considerably better. It is fairly closely related to the base exchange capacity of the soil, but the whole theory underlying its determination is so doubtful that it is impossible to give any exact meaning to the quantity so determined."

Finally, "it appears that if the box parameters and the xylene equivalent were given for the Natal soils, none of the other parameters would add very much extra information. The loss on ignition has not been studied in very great detail because an extensive preliminary examination of its properties, and particularly of the ignition losses of the natural and the peroxide-treated soils, gave results of no great importance."

The buffer capacity of peat soils, B. D. WILSON and M. J. PLICE (*New York Cornell Sta. Mem.* 146 (1933), pp. 11, figs. 2).—The buffer capacity of the soils investigated was found closely related to the initial soil reaction and base content of the soils, low acidity and a high content of bases being associated with a high buffer capacity with respect to hydrochloric acid. With respect to sodium hydroxide the order is reversed. Numerical expressions for buffer capacity, based on the milliequivalents of H ions inactivated by the soils, show a high coefficient of correlation between buffer capacity and the initial reaction of the soils. An intimate relationship between the buffer capacity

of the soils and the amount of ash and the amount of calcium which the soils contain was also demonstrated.

Removal of the exchangeable cations from the soils by means of electrodialysis reduced the buffer capacity of the soils with respect to hydrochloric acid and increased it with respect to sodium hydroxide. The organic matter of the electrodialyzed soils had little or no effect in buffering the soils against hydrochloric acid. "Undoubtedly the organic matter, of which the soils are largely composed, plays an important part in buffer action because of its capacity as an absorbing medium of cationic material. Electrodialysis increased the buffer capacity of the soils toward sodium hydroxide by increasing the soil acidity. Some of the buffer effect toward the alkali appears to be due directly to the organic matter of the soils. The results of the experiments indicate that soil reaction is a reliable index of the buffer capacity of the peat soils used in the investigation."

Oxygen absorption in soils, F. B. SMITH and P. E. BROWN (*Iowa State Col. Jour. Sci.*, 7 (1933), No. 2, pp. 153-161, pl. 1, figs. 5).—The authors of this contribution from the Iowa Experiment Station found that the results secured with the manometers do not represent oxygen absorption alone but are a resultant of several processes, of which the simplest might be oxygen absorption together with the evolution of "some noncombustible gas, insoluble in potassium hydroxide."

It was further observed that "the pressure produced in the flasks was not produced entirely by a difference in temperature either outside or inside the flask. No combustible gases (hydrogen or methane) were found. The pressure was produced at low moisture content of soil and at high concentration of oxygen. The nitrate content of the soil was low, and it seems unlikely that nitrogen gas was evolved through denitrification. It is possible, but seems unlikely, that under rapid oxidation, such as would take place with dextrose in soil in an atmosphere of oxygen, higher temperatures were reached in the experiments where a pressure was produced than were measured by the Beckman thermometer."

The rate of decay in relation to soil types and vegetative covering in Glamorgan, W. E. ISAAC (*Jour. Agr. Sci. [England]*, 23 (1933), No. 1, pp. 31-72, figs. 2).—The author investigated certain Glamorganshire soils to determine the extent to which the decomposing power of soils within a climatic region is influenced by the geological character of the rocks from which the soils are derived, and by the nature of the vegetative covering. The soils of south Glamorgan appeared in general to be Brown Earth types.

A suitable form of organic matter for the study of the decomposing power of a soil was found in crushed linseed. An apparatus found better adapted for the measurement of carbon dioxide evolution than those previously reported upon is described in detail, as are also the methods used for maintaining standard conditions of temperature, humidity, and water content of incubated soil, and for estimating the carbon dioxide evolved from the soil.

"The differences in decomposing power, although not great, are quite distinct, and in general seem to run parallel with the fertility of the soils. . . . Soils seem to show a very marked seasonal periodicity in decomposing power. . . . The seasonal differences in the decomposing power of a single soil exceed the differences between the decomposing power of different soils. The modifying effect of different types of vegetation on soils derived from the same parent rock may be slight (lower Lias) or considerable (Devonian Red Marl).

"The Glamorganshire soils examined can be arranged in the following order of increasing power of decomposition: Devonian heath and Pennant grit;

carboniferous limestone; Triassic Breccia B, Devonian woodland, and lower Lias woodland; lower Lias semiscrubland; marine alluvium; Triassic Limestone Breccia A. The differences between the respiratory power and decomposing power of a single soil are very marked and far exceed the order of the differences between the decomposing power of different soils. The differences between the respiratory power of different soils are more marked than the differences in decomposing power. A 10-day experimental period would seem the best for studying the comparative power of soils in decomposing crushed linseed."

The decomposition of certain types of forest litter under field conditions, J. G. FALCONE, J. W. WRIGHT, and H. W. BEALL (*Amer. Jour. Bot.*, 20 (1933), No. 3, pp. 196-203).—This joint contribution from the New Jersey College of Agriculture and the Dominion Forest Service of Canada reports a study of the loss by weight of stems of bracken and the litter on the forest floor in a white pine stand during the field season of 1929 and of forest litter in stands of red and jack pine in 1930.

Under like conditions of temperature and precipitation, (1) the litter in a white pine forest was found to decompose more rapidly than the litter composed of the stems of the common bracken. (2) The litter of both red and white pine was found to decompose more rapidly than the litter of jack pine. (3) The twigs of white pine were found to decompose more than twice as rapidly as those of red pine and over 4 times as rapidly as those of jack pine. (4) The twigs of red pine were found to decompose more than 1.7 times as rapidly as those of jack pine.

The loss in percentage by weight for all materials studied was found to increase with an increase in temperature and precipitation. "Thus, a mean temperature of 63.65° F., when accompanied by a total precipitation of 14.82 in., was found to be more favorable to the decomposition of the combined F and H layers in a white pine forest and the stems of the common bracken than a mean temperature of 59.85°, when accompanied by a precipitation of only 5.72 in."

The effect of a soil mulch on soil temperature, E. S. WEST (*Jour. Council Sci. and Indus. Res. [Aust.]*, 5 (1932), No. 4, pp. 236-246, figs. 8).—The layer of soil at the surface loosened by cultivation has a lower heat diffusivity than the compact soil. In the case investigated, the heat diffusivity was reduced to 0.17 of that of the original compact soil. This resulted in the soil temperature wave of cultivated soil being markedly damped as compared with that of the uncultivated soil for any specific depth below the cultivated layer. In the cultivated layer itself, the temperature wave at the surface had a greater amplitude than the temperature wave at the surface of undisturbed soil, but at the bottom of the cultivated layer the amplitude was much less in the cultivated soil than at a similar depth in the uncultivated soil. The mean temperature during the summer months, down to a depth of 60 cm, was about 2° C. lower in the cultivated soil than in the undisturbed soil.

[Astor Substation soil work] (*Oregon Sta., John Jacob Astor Branch Sta. [Pamphlet, 1933]*, pp. 2, 3, 5, 6, fig. 1).—The report contains very brief notes on current and completed work under the headings of lime, superphosphate, manure, drainage, and phosphates.

Use of the exponential yield curve in fertilizer experiments, W. J. SPILLMAN (*U.S. Dept. Agr., Tech. Bul.* 348 (1933), pp. 67, figs. 11).—The author discusses a graphic method, a logarithmic method, and a new method which makes possible the determination of the most probable value of the constants by the method of least squares. The application of the exponential yield curve to a specific case in which each of the three common plant-food elements is varied,

including the method of passing from the 1-variable form to the general form of the equation, is shown; a method for determining the quantity, if any, of each of the three common plant-food elements absorbed by the soil and held in a condition unavailable to the growing crop is presented; the form of the yield curve is discussed with a presentation of reasons given for preferring the exponential to the parabolic form; and the derivation of all the commonly employed forms of the exponential yield curve is presented. Also, formulas for determining for specific cases the optimum fertilizer formula to use, the optimum quantity of fertilizer to apply for greatest profit per acre, and for determining the optimum formula to use and the optimum acreage to which to apply a fixed quantity (value) of fertilizer for greater profit per dollar invested in fertilizer, in both presence and absence of the phenomenon of plant-food occlusion by the soil are worked out; plans for obtaining from a relatively small number of experimental plats the data necessary for determining the constants in the exponential yield equation are outlined; and the manner of utilizing check plats as a means of eliminating, insofar as this can be done, unevenness in the yielding power of the soil of the experimental field, is discussed.

On the adsorption of various ammonium compounds in the soil [trans. title], K. NEHRING and A. KELLER (*Kolloid Beihefte*, 37 (1933), No. 7-9, pp. 293-323, figs. 4).—Adsorption experiments were made upon soils of various reactions and treated with several different proportions of calcium and of sodium carbonates, with a view to determining the extent of the fixation of the ammonium radical from a number of ammonium salts.

The ammonium fixation more or less closely paralleled the adsorption capacity. The adsorption was in generally good agreement with the Freundlich adsorption isotherm theory. The effect of the accompanying anions, which was quite distinct, followed, in order of increasing effect, the lyotropic series (Cl , NO_3), SO_4 , (CO_3) , PO_4 . When the H ion of the base exchange complex of acid soils was replaced by calcium the adsorption capacity of the soil for the ammonium ion as supplied by ammonium sulfate, chloride, or nitrate was distinctly increased, an effect which was even more marked when sodium entered the exchange complex. The effects of the sodium and calcium ions are referred to the greater exchange mobility of sodium and calcium as compared with that of the H ion.

The take-up of ammonium from its phosphate and oxalate, very marked in acid soils, was noticeably lessened by increasing additions of calcium carbonate. It is considered that the calcium oxalate and phosphate formed, and more especially the calcium carbonate, which, in the cases of the larger additions, passed only partly into the state of adsorptively bound calcium, were able to enter to a certain extent into exchange reactions with the ammonium zeolite first formed. Even in the cases of ammonium salts other than the oxalate and phosphate, the tendency of the larger additions of calcium carbonate to lessen ammonium adsorption was evident. The anion effect was most marked in the cases of soils of acid reaction, being decidedly less in neutral soils. The adsorption capacity of acid soils was found to depend upon the concentration more than did that of the neutral soils.

The effect of ammonium sulphite on plant growth, A. H. LEWIS and F. B. MARKOV (*Jour. Agr. Sci. [England]*, 23 (1933), No. 1, pp. 1-5).—A review of the few recorded investigations into the effects of sulfites in the soil upon plant growth showing conflicting evidence, the authors carried out pot culture experiments to ascertain the effects on the germination, growth, and yield of mustard and rye on a heavy soil of the addition to the ammonium sulfate used as source of nitrogen of varying amounts of ammonium sulfite. Under the conditions

of the experiment, ammonium sulfite had no adverse effect on the germination, growth, and yield of dry matter either of mustard or of rye.

The value of lime on Toxaway loam and Porter's loam soils, C. B. WILLIAMS, W. H. RANKIN, and S. C. CLAPP (*North Carolina Sta. Bul.* 285 (1933), pp. 15).—Field experiments at the Mountain Substation from 1911 through 1931 indicated that for a corn, wheat, red clover rotation, the soils in question were in need both of limestone and of complete fertilizer, limestone with superphosphate alone failing to give as satisfactory a result. When the rotation consisted of potatoes, wheat, and clover, however, limestone had a bad effect on both the yield and the quality of the potatoes.

Memorandum on the lime resources of Kenya Colony, with special reference to future requirements and economy of transportation, G. H. G. JONES (*Kenya Dept. Agr. Bul.* 12 (1932), pp. 15, pl. 1).—The bulletin presents a brief account of the local situation under the headings of future requirements of limestone; sources of lime; the future annual lime requirements, under which is included brief specific consideration of such crops as coffee and tea, maize, other cereals, and sisal; the needs of different parts of the colony; special note on local supplies of lime within the Trans Nzoia; the estimation of the manurial value of phosphatic limestone deposits; and natural reserves of phosphates within the colony. Several appendixes, of which the last takes the form of a map, summarize certain details of the information collected.

AGRICULTURAL BOTANY

A textbook of botany, I-III, J. M. COULTER, C. R. BARNES, and H. C. COWLES (*New York: Amer. Book Co., rev. and enl., 1930, vols. 1, pp. VIII+310, figs. 618; 2, pp. VIII+307, figs. 87; 1931, vol. 3, pp. X+499, figs. 541*).—This is a revision of the work previously noted (*E.S.R.*, 27, p. 328). Volume 1, morphology, has been revised by Coulter; volume 2, physiology, by C. A. Shull; and volume 3, ecology, by G. D. Fuller.

A textbook of plant physiology, N. A. MAXIMOV, trans. edited by A. E. MURNEEK and R. B. HARVEY (*New York and London: McGraw-Hill Book Co., 1930, pp. XVI+381, pl. 1, figs. 152*).—This book, translated from the Russian, is claimed in an editorial note to present the fundamentals of the physiology of plants, giving examples of phases applicable in agriculture and forestry, including the important features of plant physiology that a beginning student should acquire. It is arranged in three major parts having chapters to fit it for class work. The American literature of the subject is included as source material. Russian literature is made more freely available than formerly. It is pointed out that Russia offers a wide range of ecological conditions, including frost injury and drought effects.

Julius Sachs, founder of the new plant physiology, 1832-1897, E. G. PRINGSHEIM (*Julius Sachs, der Begründer der Neueren Pflanzenphysiologie, 1832-1897. Jena: Gustav Fischer, 1932, pp. XII+302, pls. 13*).—This memorial to Julius Sachs appears in honor of his one hundredth birthday.

Regenerative organ formation in roots, H. TWELE (*Untersuchungen über Regenerative Organbildung an Wurzeln. Diss., Hamburg Univ., 1929, pp. III+33, fig. 1*).—This is a University of Hamburg thesis.

Effect of sulphur compounds in breaking the dormancy of potato tubers and in inducing changes in the enzyme activities of the treated tubers, L. P. MILLER (*Contrib. Boyce Thompson Inst.*, 5 (1933), No 1, pp. 29-81, figs. 11).—Further studies confirmed results previously noted (*E. S. R.*, 68, p. 757). Compounds found effective included ammonium dithiocarbamate, thiosemicarbazide, ethyl mercaptan, hydrogen sulfide, thioacetamide, thioglycol, methyl

disulfide, and various derivatives of dithiocarbamic acid. Thioacetamide differed from the other chemicals studied in that it retards the germination of nondormant tubers besides breaking the dormancy of dormant tubers. The probable reason for these effects is discussed.

The juices from potatoes treated with certain of these chemicals were examined as to pH, iodine absorption, catalase, and peroxidase activity, and reducing sugar and sucrose content at intervals after treatment, and compared with juices from corresponding check potatoes. In general, the treatments resulted in increases in the activity of the enzymes studied, although the extent of the increases was not a measure of the efficacy of the treatments. Large increases in sucrose resulted from the treatments, even in completely nondormant tubers which already had a relatively high sucrose content. The changes in the properties of the juices of treated potatoes in general agree with those found previously for treatments with thiourea and sodium thiocyanate.

In the case of vapor treatments of whole tubers, large increases in the respiratory activity resulted, while such large increases did not occur after treatment of cut pieces. The increases in enzyme activity found in the case of the treatments evidently were due to a tissue response of the treatments and not to any direct effect on the enzymes. The chemicals added directly to the juices had a very marked effect in retarding the darkening which normally occurs when potato juice is exposed to the air. This was manifest even in very dilute concentrations of chemicals.

Normal growth of potato leaves in greenhouse and field, W. E. STONE (*Jour. Agr. Res. [U.S.]*, 46 (1933), No. 6, pp. 565-578, figs. 9).—A record of the growth of normal potato leaves in greenhouse and field during the early part of the summer, when optimum conditions for plant growth prevail, was made at the Vermont Experiment Station to ascertain the period of maximum surface expansion under normal conditions during both day and night. See also an earlier note (E.S.R., 68, p. 311). All leaves on a single potato shoot on plants of the Green Mountain variety were measured at intervals for a period of about 20 days in the greenhouse during May and in the field in July.

The growth of leaflets and leaves followed the typical S-shaped curve. The leaves first formed ceased growing during the early part of the observations, and the next younger leaves then began rapid growth. When the observations terminated the youngest leaves were just beginning this period of accelerated growth. The growth rate of leaflets composing a single leaf was not always the same on any single day. The growth of a shoot continued after the flower clusters were formed, a new vegetative shoot pushing them to one side. In this manner, the shoot continues to grow and the foliage to increase in spread. Measurements on rapidly growing leaflets showed the night growth in greenhouse plants to be 54.1 percent and the day growth 45.9 percent, and the night growth in outdoor plants to be 56.8 percent and the day growth 43.2 percent. The accelerated growth of each leaf seemed to be checked by the development of a newer leaf. The checking of vegetative growth in the potato plant, however, did not seem due to flower formation, for growth continues after flower clusters have appeared.

The upward movement of inorganic solutes in plants, H. F. CLEMENTS (*Wash. State Col., Res. Studies*, 2(1930), No. 3, pp. 91-106, figs. 5).—Chemical and anatomical studies regarding translocation activities in *Vitis vinifera*, *Rubus occidentalis*, *R. idaeus strigosus*, *R. neglectus*, *Pyrus malus*, *Prunus americana*, and *P. persica* show a continuation after girdling of the upward movement of the ash constituents and nitrates in stems of grape, raspberry, and plum. It is thought that the distribution of tracheae in the seasonal development of xylem constitutes to a large degree the factor which determines

the ease with which plants tolerate girdling. Ash solutes apparently are carried by the xylem stream. Views of others are critically discussed.

Transpiration in plants, I, II [trans. title], A. SEYBOLD (In *Ergebnisse der Biologie*. Berlin: Julius Springer, 1929, vol. 5, pp. 29-165, figs. 38; 1930, vol. 6, pp. 559-731, figs. 40).—The first of these communications deals with the physics of transpiration, the energy involved, the methods of its measurement, the contributory factors, and the transpiration system and the physical components of transpiration; the second with the physiology and the ecology of transpiration.

The effect of the 1932 eclipse upon the width of stomatal openings in gray birch, J. L. DEEN and M. H. BRUNER (*Ecology*, 14 (1933), No. 1, pp. 76, 77, fig. 1).—A graphic representation of microscopic measurements made at 15-minute intervals of the width of the stomatal openings in gray birch leaves during August 31, the day of the eclipse, and during subsequent days showed an influence of the abnormal light conditions prevailing during the eclipse.

Respiration of cranberry plants in relation to water injury, H. F. BEAGMAN (*Amer. Cranberry Growers' Assoc. Proc. Ann. Meeting*, 60 (1930), pp. 21-25).—Following measurements of respiratory activity in various parts (buds, blossoms, fruits, and leaves) of the cranberry plant, it is stated that the injury to vines resulting from flooding was due almost entirely to lack of oxygen (asphyxiation) and not notably to any chemically injurious substance in the water. Factors in this outcome are activity of the vines at submergence; temperature of the water; weather conditions, particularly clear or cloudy sky; and source of water supply. Buds, small fruits, and growing tips are most apt to be injured since they respond most rapidly and require the most oxygen.

Some carbohydrate changes in shelled green peas, Z. I. KERTESZ (*New York State Sta. Bul.* 622 (1933), pp. 14, fig. 1).—Asserting that the supposition that sugars are transformed into starch in shelled green peas is without foundation and has probably arisen from the fact that starch remains practically unchanged while other constituents are lost in respiration, the author emphasizes the fact that the methods of sampling and calculation are mostly responsible for the few data in the literature which seem to bear out this supposition. In the experiments reported no evidence was found of any transformation of sugar into starch during storage. Some increase was noted in other acid hydrolyzable higher carbohydrates and in the fraction insoluble in 80 percent hot alcohol, but because of fluctuations observed no definite deductions could be drawn.

Botanical-serological studies, B. K. BOOM (*Botanisch-serologische Onderzoekingen. Proefschr., Landb. Hoogeschool, Wageningen*, 1930, pp. [10]+77).—This doctor's thesis contains references to related work by about 100 authors.

The influence of ultraviolet rays on the life relations of soil bacteria [trans. title], A. SCHEITZ (*Arch. Mikrobiol.*, 1 (1930), No. 4, pp. 577-598, figs. 5).—The chemically active rays from the Vitalux lamp affect unfavorably the numbers of living aerobic soil bacteria, this effect being modified by the thickness of the soil layer and the duration of the exposure. In case of thin layers, most of the bacteria die during the first hour; afterwards progressively fewer remain alive. Sunshine has a similar effect, though no laws were determined.

Mycorrhiza in relation to tree growth, M. C. RAYNER (*Empire Forestry Jour.* [London], 9 (1930), No. 2, pp. 182-189).—"In the case of young conifer plantations, for example, it has been observed that poor growth and a condition of check is marked by absence of mycorrhiza, and that emergence from this unsatisfactory condition is correlated with its free development. It remains for careful research to demonstrate a causal relation between the two phenomena."

GENETICS

Evolution, genetics, and eugenics, H. H. NEWMAN (*Chicago: Univ. Chicago Press, 1932, 3. ed., pp. XXIV+620, figs. 100*).—This is a revision of the book previously noted (E.S.R., 55, p. 223). The first two parts are devoted to a historical account of the development of the theory of organic evolution and the evidences for it. The third and fourth parts have been largely rewritten and deal with genetic principles as applied to plant and animal breeding and eugenics, emphasizing these as the mechanism of evolution.

Recent revivals of Darwinism, H. F. OSBORN (*Science, 77 (1933), No. 1991, pp. 199-202*).—After briefly referring to the tendency of J. B. S. Haldane, J. S. Huxley, and T. H. Morgan to revert to the ideas of more or less pure Darwinism as regards evolution, the author refers to the historic explanations of the modes and causes of evolution as set forth by Lamarck, Geoffroy St. Hilaire, and Aristotle. Following this he expresses the view that the underlying causes of evolution are entirely unknown and may prove to be unknowable.

Inheritance in barley, D. W. ROBERTSON (*Genetics, 18 (1933), No. 2, pp. 148-158*).—Further genetic studies with barley (E.S.R., 67, p. 375; 69, p. 29) at the Colorado Experiment Station dealt with the inheritance of simple Mendelian factor pairs and their possible linkage relations. The inheritance of the character pairs intermedium v. nonintermedium, *Ii*, green v. white seedlings in Black Hull-less, *Abaa*, and purple v. white straw color, *Pr pr*, was explained on a simple Mendelian basis. The factor pair, *Fcfc*, for green v. chlorina seedlings was found to be inherited independently of *Nn* of group III, *Kk* of group IV, and *Ss* of group V. It was previously found to be inherited independently of factors in group I, II, and VI. *Ii* was found to be linked with *Kk* with 15.12 ± 0.065 percent crossing-over, while *Vv* was found to be inherited independently of *Kk*, indicating that *Vv* and *Ii* are not in the same linkage group. *Abaa* was found to be inherited independently of *Kk* and *Nn*, but was linked with *Ss* with a percentage cross-over of about 26. *Pr pr* was found to be linked with *Vv* with a cross-over value of 9 ± 0.68 , but inherited independently of *Ii*.

The present study added another linkage group to the six already found. *Fcfc* was found to be inherited independently of at least one factor pair in each of the already known groups. *Ii* was added to group IV, *Abaa* to group V, and *Pr pr* to group I.

Inheritance of an anomaly in corn [trans. title], M. BONVICINI (*Italia Agr., 69 (1932), No. 8, pp. 716-722, figs. 11*).—Unusual development of the palea in certain strains of corn persisted from year to year, being expressed most in dry years when it even occurred in varieties not showing it before. The tendency seemed to be inherited in certain varieties, although affected by drought.

The genetics of Gossypium, S. C. HARLAND (In *Bibliographia Genetica. 's Graevenhage (The Hague): Martinus Nijhoff, 1932, vol. 9, pp. 107-182*).—This review of genetic investigations with cotton discusses observations reported from research concerned with the taxonomy, classification, species, and cytology of *Gossypium*; the inheritance of plant, leaf, flower, boll, lint, seed, and physiological characters; and correlations of genetic significance between characters; and includes a list of genes with indicated linkage relations. The bibliography embraces 76 titles.

Natural crossing in cotton, M. A. FIKRY (*Roy. Agr. Soc. Egypt, Tech. Sect. Bul. 18 (1931), pp. 23, pls. 3*).—The average cumulative percentage of natural crossing between Maarad and Red Leaf Acala cotton was found to be 4 percent.

A gradient of pollen starting from the pollen source and falling to zero as it ran away from the source of foreign pollen on both sides was established. The maximum range of pollen transmitted was about 40 m.

Fluorescence of *Lolium* seedlings in ultra-violet light, P. A. LINEHAN and S. P. MEMON (*Nature* [London], 131 (1933), No. 3302, pp. 202, 203).—Selfing, hybridization, and back-cross experiments with *L. perenne* and *L. multiflorum*, made to ascertain the mode of inheritance of factors responsible for the ultra-violet light fluorescence reaction, produced data confirming original expectations. The capacity to fluoresce appeared to be heritable. *L. perenne* normally is pure for nonfluorescence and *L. multiflorum* for fluorescence. Fluorescence is dominant in the F_1 of pure fluorescent \times pure nonfluorescent, the F_2 giving a ratio not significantly different from 3 fluorescent to 1 nonfluorescent. The back-cross $F_1 \times$ pure fluorescent gave all fluorescent progeny, and the back-cross $F_1 \times$ pure nonfluorescent gave a ratio of about 1 to 1. No genetic linkage was found between fluorescence and the possession of awns on the lower flowering glumes, shoot veneration, longevity, or vigor. Some of the conclusions agreed with those of Corkill (E.S.R., 68, p. 602), and the content of fluorescence reactors in a given strain seemed to provide a gauge of agronomic merit.

Embryo development in *Nicotiana* species hybrids, F. A. MCCRAY (*Genetics*, 18 (1933), No. 2, pp. 95–110, figs. 8).—Eight crosses were made between different species of *Nicotiana*, 2 in each of 4 different groups based on the success of the hybrid. Fertilization, with 3 exceptions, was found to take place on the seventh day. The complete development of the *Nicotiana* embryo from the fertilized egg, described and illustrated, resembles that found in other dicotyledonous angiosperms.

N. rustica \times *N. glauca* and *N. rustica* \times *N. longiflora*, of group 1, completed only one or two cell divisions, did not grow at all, and lived only a day or two. *N. rustica* \times *N. rusbyi* and *N. rustica* \times *N. palmeri*, of group 2, experienced a number of cell divisions so that 16 to 32 cell stages appeared, but failed to make appreciable growth. The embryos of group 3 hybrids, which give a partial germination but die soon after, attained their full size as well as those of group 4. The growth of embryos of hybrids of group 3, *N. nudicaulis* \times *N. tabacum* and *N. suaveolens* \times *N. tabacum*, did not differ essentially from that of embryos of hybrids of group 4. In each case the hybrid embryo curve simulated that of the maternal parent but always fell somewhat below it, even in the most successful crosses, *N. tabacum* \times *N. glauca* and *N. paniculata* \times *N. glauca*. All interspecies crosses are classified in 9 categories, based on the results obtained, ranging from no stimulation in the ovary—complete failure—to the production of fertile or partially fertile hybrids. See also an earlier note (E.S.R., 68, p. 749).

A tri-generic hybrid of *Zea*, *Tripsacum*, and *Euchlaena*, P. C. MANGELSDORF and R. G. REEVES (*Amer. Nat.*, 67 (1933), No. 708, pp. 82, 83).—The hybrid of *Zea* \times *Tripsacum*, according to Texas Experiment Station studies (E.S.R., 67, p. 518), produces a small percentage of functional female gametes, all of which possess the somatic number of chromosomes. This hybrid, when pollinated with *Euchlaena*, exhibits a fertility of about 6 percent, and the triple hybrid resulting from this cross has 38 chromosomes comprising, presumably, 1 genom of 10 from *Zea*, 1 of 18 from *Tripsacum*, and 1 of 10 from *Euchlaena*, apparently combining in 1 plant all the germ plasm of 3 distinct genera. While various characters of each parent are expressed in the hybrid, in general, it resembles *Euchlaena* more than the other 2 parents. Cytological studies at meiosis indicated that there is almost complete pairing of *Zea* and *Euchlaena* chromosomes to form 10 bivalents, while the 18 *Tripsacum* chromosomes behave

as univalents. Little, if any, pairing of *Tripsacum* chromosomes occurs with those of *Zea* and *Euchlaena*.

Studies in the genetics and the cytology of *Ustilago avenae* and *Ustilago levis*, C. S. HOLTON (*Minnesota Sta. Tech. Bul.* 87 (1932), pp. 34, pls. 20).—Genetic and cytological studies revealed two sex groups in *U. avenae*, which causes loose smut of oats, and *U. levis*, responsible for covered smut. Segregation for sex evidently is complete in either the first or the second meiotic division. After mating monosporidial lines of opposite sex, from 35 minutes to several hours was required for fused sporidia to appear in culture. The stages in the fusion process were the production of a projection by one (active) sporidium and the elongation of this projection until it comes into contact with a sexually opposite (passive) sporidium, fusion of the sporidia followed by a decided elongation of the fusion tube, and subsequent production of the infection hypha.

Sporidial fusions in culture and the production of chlamydospores on the host showed that *U. avenae* and *U. levis* hybridize readily. Artificial inoculations with crosses between monosporidial lines of *U. avenae* produced both the loose and covered smuts, while *U. levis* produced only the covered smut. Crosses between *U. avenae* and *U. levis* produced loose, covered, and intergrading types of smut. It seems that both the loose and covered types of smut may be produced on the same variety by the same cross, and that the same cross may produce loose smut on one variety and covered smut on another, whereas the same cross may produce the same type of smut on as many as three different varieties.

Sporidia isolated from germinating hybrid chlamydospores were usually nonculturable. A cross between monosporidial lines from hybrid chlamydospores produced a buff smut, a new and previously undescribed type having hyaline and smooth chlamydospores. The production of this type of oat smut furnished evidence that new physiologic forms of the oat smut fungi may be produced by hybridization between the two species.

Segregation data showed that hybrid chlamydospores are always echinulate, indicating dominance of echinulation over smoothness, and that olive-brown color is dominant over hyalineness. It appears that segregation of factors for cultural characteristics may extend indefinitely beyond the second nuclear division in meiosis. Successively produced sporidia from the same promycelial segment frequently developed distinctly different cultural lines. There was evidence that segregation of factors for cultural characteristics takes place in monosporidial lines. No concrete evidence for mutation in *U. avenae* and *U. levis* was obtained. Cultural variants appearing as sectors in monosporidial lines were interpreted as being the result of segregation.

Cytological studies showed that the sporidia of *U. avenae* and *U. levis*, each promycelial cell and primary sporidium, and the mycelium of monosporidial cultures are all uninucleate. Attempts to stain fusing sporidia were unsuccessful, but according to studies by C. C. Allison fused sporidia initiate the dikaryophase, which is binucleate. This stage persists throughout the parasitic stage to the production of chlamydospores which, when mature, have a single diploid nucleus.

Inheritance in Albit wheat of resistance to bunt, *Tilletia tritici*, E. N. BRUSSMAN and L. E. HARRIS (*Jour. Agr. Res. [U.S.]*, 46 (1933), No. 4, pp. 361-365, figs. 2).—Further studies at the Oregon Experiment Station (E.S.R., 65, p. 747) gave evidence that Albit wheat contains one main dominant factor (*MM*) for resistance to certain physiologic forms of bunt, the same as carried by its male parent, White Odessa, and found by Briggs (E.S.R., 62, p. 646; 65, p. 345) or by the authors in Martin, White Odessa, Hussar, Banner Berkeley,

and possibly Regal. Albit has morphological characters resembling its female parent, Hybrid 128, and the bunt resistance of White Odessa.

Inheritance of bunt reaction and other characters in Hope wheat crosses. J. A. CLARK, K. S. QUISENBERRY, and L. POWERS (*Jour. Agr. Res. [U.S.]*, 46 (1933), No. 5, pp. 413-425, figs. 2).—The parent reaction to bunt and the segregation in F₂ hybrid strains for the wheat crosses Hope × Marquis, Hope × Ceres, and Hope × Hard Federation, were studied cooperatively by the Montana Experiment Station and the U.S. Department of Agriculture.

Hope was found to be strongly resistant, Marquis weakly resistant, Ceres weakly susceptible, and Hard Federation strongly susceptible. Hope × Hard Federation showed a strong tendency for dominance of susceptibility. In Hope × Ceres an intermediate inheritance was indicated, but with considerable less than one fourth within the limits of each parent, while in Hope × Marquis a tendency toward a dominance of the stronger resistance of the Hope parent was noted. Indications were that the stronger the degree of resistance involved in the hybrids the less complex was the inheritance.

Additional studies in the Hope × Hard Federation populations showed the bunt percentage to be about one fourth the percentage of infected plants. An increase of 5 percent in bunt caused a decrease of about 4 percent in yield. Glume color was shown to be controlled by a single genetic factor and kernel color by at least three factors. The expression of awnedness was rather variable, but two major factors were evident. No important relation was observed between awnedness and bunt or yield.

Chromosome numbers in aneuploid apple seedlings. B. R. NEBEL (*New York State Sta. Tech. Bul.* 209 (1933), pp. 12).—Studies of the chromosome complex of apple seedlings resulting from the crossing of diploids with triploids, triploids with diploids, and triploids with triploids showed all the resulting seedlings to be aneuploid, that is, to possess irregular numbers of chromosomes. An analysis of the data indicated that the basic number of chromosomes in Pomoidae is 7. When the observed numerical values were compared with a calculated normal frequency curve deviations of the observed values occurred where expected in case the number 7 exerts a disturbing influence. Similar comparisons for the number 8 did not meet the facts equally as well.

Since all the aneuploid seedlings obtained had no practical value, the author suggests that the artificial production of polyploid apples must be attacked by other methods.

Chromosome pairing, structural hybridity, and fragments in Rosa. E. W. ERLANSON (*Bot. Gaz.*, 94 (1933), No. 3, pp. 551-566, figs. 23).—Multiple pairing of chromosomes due to reduplication and reciprocal translocation of segments was observed at the University of Michigan in diploid roses belonging to the species complexes *R. multiflora*, *R. blanda*, *R. woodsii*, and *R. pisocarpa*. Although gametes with 8 chromosomes were sometimes observed, no diploid was found with a reduplicated whole chromosomes. Multivalent associations of chromosomes are believed to occur frequently among tetraploid roses but are relatively rare in hexaploids and octoploids. Triploids, probably originating from unreduced gametes without hybridization, were found in diploid cultures of *R. blanda*, *R. macounii*, and *R. pisocarpa*. The exceptional types of pairing found in Rosa are said to be in conformity with the chiasma theory of pairing.

[Papers in animal genetics] (*Amer. Soc. Anim. Prod. Proc.* 1932, pp. 265-291).—The following papers were presented before the genetics section of the 1932 meeting of the American Society of Animal Production:

The Evidence for Genetic Resistance to Bacterial Disease in Animals, by W. V. Lambert (pp. 265-269); The Effect of Selection on the Resistance of a Population, by J. W. Gowen (pp. 269-271); The Commercial Possibilities and

Limitations of Breeding for Disease Resistance, by L. J. Cole (pp. 271, 272); The Inheritance of Milk Production and Butterfat Percentage in a Herd of Purebred Ayrshire Cattle, by E. E. Helzer (pp. 273-277); Breeding Results in a Herd of Cattle Infected with Contagious Abortion, by W. W. Yapp and A. F. Kuhlman (pp. 277-281); Foetal Resorption in Animal Husbandry, by R. B. Hinman (pp. 282, 283); The Sex Ratio in the Mule, by W. A. Craft (pp. 283-285); and Multiple Births in Sheep, by I. Johansson (pp. 285-291).

This supplements the list of papers in animal production (page 404).

Variability and individuality, C. C. LITTLE (*Science*, 77 (1933), No. 1990, pp. 195-197).—Data are cited which show greater variability in the size of litters born to young and old mice than was observed in the litters of medium-aged dams. Similar results are cited on the crossing over in *Drosophila* females of different ages. The data suggest that there is more variability in the offspring of old and young dams than in the offspring of medium-aged dams, emphasizing the importance of recognizing the part played by the age factor in variability and individuality.

On the inheritance of markings in black-spotted Holstein cattle [trans. title], M. SOMMER (*Wiss. Arch. Landw., Abt. B, Arch. Tierernähr. u. Tierzucht*, 8 (1932), No. 1, pp. 110-149, figs. 2).—An analysis was made of the inheritance of black spotting in the three herds of cattle previously discussed by Lauprecht (E.S.R., 56, p. 223). A single pair of Mendelian factors seemed to explain the inheritance of markings on the head and over the body with dominance incomplete. From the theoretical determination of the genotype of the parents it was concluded that the offspring should occur in the following proportions, 218 AA, 326 Aa, and 121 aa; whereas the numbers observed were classed phenotypically as 227 AA, 320 Aa, and 118 aa. In these matings A refers to spotting and a is the solid color.

[Multinipple sheep] (*New Hampshire Sta. Bul.* 270 (1933), p. 6).—A progress report is given by E. G. Ritzman of the results of crossing Southdown-Rambouillet sheep with the multinipple strain established by Alexander Graham Bell.

Studies on inbreeding in some degenerating breeds of dogs [trans. title], E. F. LISSITSKIĖ (LISSITZKY) (In *Trudy Vsesoiuznogo S"ezda po Genetike, Selektii, Semenovodstvu i Plemennomu Zhivotnovodstvu* (Proceedings of the U.S.S.R. Congress of Genetics, Plant- and Animal-Breeding), Leningrad, 1929. Leningrad: Izd. Redaktsionnoi Kollegii S"ezda, 1930, vol. 6, pp. 155-162, figs. 2; Ger. abs., pp. 161, 162).—Inbreeding in bulldogs was found to result in such abnormalities among the offspring as harelip and wolf neck, and it lowered disease resistance, reduced fertility, and caused sterility. The mortality before and during the first month after birth and susceptibility to a variety of diseases were increased.

Lethal action in the short-tailed mutation in the house mouse, P. CHESLEY (*Soc. Expt. Biol. and Med. Proc.*, 29 (1932), No. 4, pp. 437, 438).—A study of the embryos in brachyury \times brachyury matings showed that death of about one fourth of the mice occurred during the third quarter of the tenth day of pregnancy. Deformities were present in homozygous embryos removed from the uterus early on the tenth day. Resorption of these embryos had started on the eleventh day. Of 256 embryos examined on the eighth, ninth, and tenth days of gestation, 60 were abnormal and were designated as homozygous for the short-tailed character.

Inheritance of rate of growth in domestic fowl.—I, Methods and preliminary report on results obtained with two breeds, M. LEANES and V. S. ASHMEAD (*Sci. Agr.*, 12 (1932), No. 11, pp. 652-664, figs. 5).—Data are re-

ported on the rate of growth in weight and length of the tarsometatarsus to 12 weeks of age for males and females of the Ancona and Light Sussex breeds and the F_1 , F_2 , and backcross generations of the F_1 s to the parents. The rate of growth was determined by the formula $\frac{100(W_2 - W_1)}{\frac{1}{2}(W_1 + W_2)}$, wherein W_1 was the original weight and W_2 the final weight. The data indicate inherent differences in the rate of growth of the two breeds. A close correlation of $+0.752 \pm 0.045$ was found between weight and length of the tarsometatarsus, but genetic differences were apparent. The correlations between rate of growth and weight and tarsometatarsal length were not significant. The F_1 generation was less variable than the F_2 s, but only slightly so and not in all cases. The greater growth rate seemed dominant, but it was suggested that a complex of factors is involved.

Investigations of the developmental physiology of bird feathers [trans. title], O. KUHN (*Ztschr. Wiss. Biol., Abt. D, Arch. Entwickl. Mech. Organ.*, 127 (1932), No. 3, pp. 456-541, figs. 78).—A description is given of feather development and the influence of position on the body, age, and season on the development and pigmentation of feathers.

On the morphogenesis of the fat-rump ("kurdiuk") and the tail of the sheep [trans. title], S. N. BOGOLUBSKIĖ (BOGOLUBSKY) (In *Trudy Vsesoiuznogo S"ezda po Genetike, Selektzii, Semenovodstvu i Plemennomu Zhivotnovodstvu* (Proceedings of the U.S.S.R. Congress of Genetics, Plant- and Animal-Breeding), Leningrad, 1929. Leningrad: Izd. Redaktsionnoi Kollegii S"ezda, 1930, vol. 6, pp. 53-59, figs. 3; Ger. abs., pp. 57-59).—Studies of the morphology of the fat rump and tail of sheep were made on embryos. These showed that the tail and fat-rumped characters developed at a relatively early age.

Is there an acquired specific poison supersensitivity transferred to the offspring? [trans. title] A. BLUHM (*Biol. Zentbl.*, 52 (1932), No. 11-12, pp. 667-673).—Data are presented from experiments with mice to indicate that the offspring to parents sensitized to ricin are themselves supersensitive to this toxin. The findings are based on the mortality and growth rates of the young of both sexes from treated and control parents. Tests with other toxins, such as the venom from the cobra and puff adder, are also reported.

There was a sex difference in the transmission of the sensitivity to the poisons, as the offspring of females from the immunized strains mated with normal males showed greater survival when treated with the poisons than the offspring of males from the immunized strains mated with normal females.

The physical chemistry of sexuality, P. JOYET-LAVERGNE (*La Physico-chimie de la Sexualité*. Berlin: Borntraeger Bros., 1931, pp. XI+457, figs. 12).—Various aspects of sexuality in plants and animals are discussed, including differences in the chemistry and metabolism of the two sexes.

Development of the human ovary from birth to sexual maturity, C. S. SIMKINS (*Amer. Jour. Anat.*, 51 (1932), No. 2, pp. 465-505, pls. 6).—The growth of the human ovary from the sixth fetal month to maturity is reported. The estimated number of primordial follicles in the ovary showed a decrease from 143,000 at birth to 10,500 at 14 years of age. Delivery of germ cells from the germinal epithelium ceases at the sixth month of fetal life, and the oogonia no longer multiply by mitosis.

The normal development of the mammary gland of the male and female albino mouse, C. W. TURNER and E. T. GOMEZ (*Missouri Sta. Res. Bul.* 182 (1933), pp. 43, figs. 64).—In the two parts of this bulletin dealing with the intrauterine and extrauterine life, the normal development of the mammary gland of the male and female albino mouse is described from its earliest

appearance in the 10-day-old embryo through birth, puberty, pseudopregnancy, pregnancy, lactation, and involution in a manner similar to the descriptions of the development of the mammary gland in cattle and rats (E.S.R., 66, p. 424).

A study of the cytoplasmic inclusions and nucleolar phenomena during the oogenesis of the mouse, R. A. R. GRESSON (*Quart. Jour. Micros. Sci. [London]*, n. ser., 75 (1933), No. 300, pp. 697-721, pls. 2, figs. 9).—The results are reported of a study of oogenesis in the mouse, giving special attention to the Golgi apparatus in the developing ovum in the ovary and in ova fixed in the Fallopian tubes at short intervals after mating.

Effects of hypophyseal extracts on sexually immature monkeys, F. L. HISAW, H. L. FEVOLD, and S. L. LEONARD (*Soc. Expt. Biol. and Med. Proc.*, 29 (1931), No. 2, pp. 204-206).—The daily administration to immature monkeys of extracts of the anterior lobe of the hypophysis equivalent to 1 g of dried pituitary powder was followed in from 2 to 3 days by a purplish coloration of the perianal region and a reddening of the nipples. Neither these injections nor those continued up to from 14 to 16 days caused corpus luteum effects, and ovulation did not occur.

Long continued injections of acid extract of anterior pituitary on thyroid gland and sex organs, L. LOEB and H. FRIEDMAN (*Soc. Expt. Biol. and Med. Proc.*, 29 (1931), No. 2, pp. 172-174).—In studying the influence of long continued injections of an acid extract of the anterior lobe of the pituitary, doses of from 47 to 135 cc of the extract were administered to 10 guinea pigs weighing from 185 to 205 g over periods of from 47 to 74 days. In some animals a marked hypertrophy of the thyroid glands occurred with little gain in body weight; whereas in others the thyroid glands were not greatly changed in size and normal growth occurred. The ovaries varied from normal in animals without the thyroid hypertrophy, and normal weight increased to hypotypical ovaries with much interstitial tissue and the secondary sex glands in the resting stage. There was a marked difference in the ability of young guinea pigs to tolerate heavy doses of the anterior pituitary extracts over long periods.

Effects of castration leaving the epididymis intact in the rat, J. J. LAWLESS (*Soc. Expt. Biol. and Med. Proc.*, 29 (1931), No. 2, p. 232).—The removal of the testes, leaving the epididymis intact, in eleven 3-weeks-old rats had no different effect on the rats as determined at 80 days of age than complete castration.

The anterior pituitary sex hormone of normal and semicastrated rats. F. E. EMERY, P. W. BASH, and W. R. LEWIS (*Soc. Expt. Biol. and Med. Proc.*, 29 (1931), No. 1, pp. 42-44).—In determining the influence of semicastration of male and female rats on the secretion of the hormone of the anterior lobe of the pituitary gland, two pituitary glands were removed from experimental animals and grafted into recipients at 25 and 26 days of age. The ovaries and uteri from the test animals were dissected at 30 days of age. Grafts from normal and semicastrated donors produced equal development of the ovaries and uteri in the immature animals, but the pituitaries from males were more potent than those from females.

The absence of gonad-stimulating hormone in the urine and blood of patients with pituitary tumors, J. W. WATTS (*Soc. Expt. Biol. and Med. Proc.*, 29 (1932), No. 4, pp. 396-399).—No gonad-stimulating hormone was demonstrated in the blood or urine of 7 men and 7 women with pituitary tumors when total injections of as much as 7.5 cc of blood and 24 cc of urine were administered to immature rats.

Gonad-stimulating hormones in hypophysectomised animals, J. B. COLLIP, H. SELYE, and D. L. THOMSON (*Nature [London]*, 131 (1933), No. 3293,

p. 56).—Studies of more than 600 hypophysectomized rats showed that the resulting degeneration of the germinal epithelium and interstitial tissue of the testes and the secondary sex glands was prevented, except for the degeneration of the germinal epithelium, by treatment with the anterior pituitary-like hormone of the human placenta.

Prolan, the hormone from pregnancy urine, was found to act on the ovaries of hypophysectomized females. Females operated on before sexual maturity failed to show oestrus, and pseudocorpora lutea developed in the ovary; whereas females operated on after maturity showed continuous oestrus after administration of pregnancy urine.

Hypophysectomy after parturition leads rapidly to failure of milk secretion. Hypophyseal implants permitted complete normal growth and glandular development.

The gonadotropic hormones (ρ -factors).—III, Further purification and properties of the active principles, P. G. MARSHALL (*Biochem. Jour.*, 26 (1932), No. 4, pp. 1358–1364).—Continuing this series (E.S.R., 69, p. 33), a product was obtained through ultrafiltration which contained 200 mouse units per milligram of the ρ -factor. Rupture of the follicles with probable ovulation in 24 hours was induced in the rabbit. Purification tests with phosphotungstic acid and permutit gave negative results. The chemical composition of the purified substance is given.

The assay of testicular hormone preparations. V. KORENCHEVSKY (*Biochem. Jour.*, 26 (1932), No. 2, pp. 413–422).—Litter-mate pairs of control rats and rats injected with testicular hormone preparations were dissected, and the deviations from the average in the weights of the prostate and seminal vesicles, penis, adrenals, thyroids, hypophysis, and retroperitoneal fat per unit of body weight were compared. Castration results in a decrease in the weight of the prostate, seminal vesicles, penis, and thyroids, and an increase in the weight of the hypophysis, adrenals, and body fat, but injection of the testicular hormone resulted in a change in the organs toward the normal. As a simple and sensitive test an increase of 40 percent in the weight of the seminal vesicles and prostate is suggested as a positive finding for the presence of testicular hormone in the material under test.

Castrated rats for the assay of testicular hormone. V. KORENCHEVSKY (*Biochem. Jour.*, 26 (1932), No. 4, pp. 1300–1305).—The weights of the sexual and endocrine organs, noted in the preceding paper, were found to vary in 88 rats depending on whether castration was performed before or after sexual maturity. The weights of the organs are given for the different aged animals castrated before and after maturity. Special emphasis is given to the importance of having the animals at the same age at castration and when killed for determining the testicular hormone present in comparable experiments.

The response of castrated male rats to the injection of testicular hormone. V. KORENCHEVSKY, M. DENNISON, and R. SCHALIT (*Biochem. Jour.*, 26 (1932), No. 4, pp. 1306–1314).—Continuing the above studies, it was found that the increase in the size of the prostate and seminal vesicles of males castrated before sexual maturity gave the most sensitive test for the assay of the testicular hormone, and that the penis and thymus were more variable and less sensitive. Rats belonging to different litters showed similar response to the same dose of testicular hormone, provided they were tested at similar intervals after castration and provided that castration was performed either before or after sexual maturity in both cases.

The increase in the size of the prostate and seminal vesicles was correlated with the size of the dose. The minimum dose for seven daily injections that

will induce an increase of 40 percent in the weight of the seminal vesicles and prostate of three litters of rats castrated before 30 days of age is suggested as the standard for a rat unit of testicular hormone.

The influence of the freshness of the testes and of desiccation of the testicular tissue on the yield of testicular hormone, V. KORENCHESKY, R. SCHALIT, and D. GRAETZ (*Biochem. Jour.*, 26 (1932), No. 2, pp. 423-428).—In a series of five experiments it was shown that the yield of testicular hormone was greater from fresh testes than from testes kept for about 20 hours at room temperature before extraction. On the contrary, drying of testes did not appreciably decrease the yield of the hormone provided the testes were first boiled in acidulated water to destroy all germs. The dried material was then extracted with benzene. Such extracts were compared with extracts of fresh tissue prepared by the method of Gallagher and Koch.¹

The development and morphology of the gonads of the mouse.—IV, The postnatal growth of the testis, I. W. ROWLANDS and F. W. R. BRAMBELL (*Roy. Soc. [London], Proc., Ser. B*, 112 (1933), No. B 776, pp. 200-214, figs. 9).—Continuing this series (*E.S.R.*, 60, p. 219), data are reported on the development of the testes of the mouse from birth to 300 days of age. The area of spermatid tubules was determined with reference to age and cleaned body weight. The maturation of the testes was also studied, and the maximum number of primary spermatocyte nuclei in pachynema was observed on the fourteenth day, with the first appearance of mature sperm on the forty-second day of age. The maximum growth rate of the testes occurred at from 30 to 40 days of age, when the largest area of spermatid tubules was observed in comparison with the area of intertubular material in the testes. No general wave of germ-cell degeneration was observed between birth and maturity.

Homology of prooestrous bleeding in the dog, R. K. MEYER and S. SAIKI (*Soc. Expt. Biol. and Med. Proc.*, 29 (1931), No. 3, pp. 301-303).—Evidence is presented to indicate that prooestrous bleeding in the bitch is not homologous with the menstruation of primates. Prooestrous bleeding in the dog is due to direct or indirect action of the oestrous hormone on the uterus.

The chemical and physiological properties of crystalline oestrogenic hormones, J. S. L. BROWNE (*Canad. Jour. Res.*, 8 (1933), No. 2, pp. 180-197).—The chemical nature of a crystalline substance exhibiting oestrogenic properties is described. The substance was active on immature rats, but relatively inactive on ovariectomized adults. The response of castrated females was restored by ovarian grafts.

A synthetic oestrus-exciting compound, J. W. COOK, E. C. DODDS, and C. L. HEWITT (*Nature [London]*, 131 (1933), No. 3298, pp. 56, 57).—In studies of synthetic oestrus-exciting compounds it was found that "1-keto-1:2:3:4-tetrahydrophenanthrene is capable when injected into castrated animals of inducing oestrus of an exactly similar type to that obtained by the injection of oestrin."

External evidence of hormone action following injection of urine of pregnant women into rabbits and guinea pigs, E. L. and A. G. KING (*Soc. Expt. Biol. and Med. Proc.*, 29 (1932), No. 4, pp. 469, 470).—In an attempt to develop a pregnancy test which might be employed without sacrificing the test animal, it was found that the vaginal smear of rabbits and the opening of the vaginal membrane in guinea pigs injected with pregnancy urine were unreliable.

Effect of theelin on immature guinea pigs, E. L. and A. G. KING (*Soc. Expt. Biol. and Med. Proc.*, 29 (1932), No. 9, pp. 1060-1063).—The use of immature guinea pigs for demonstrating the presence of theelin by enlargement of

¹ *Jour. Biol. Chem.*, 84 (1929), No. 2, pp. 495-500.

the uterus is suggested. In the normal animal the ratio of the weight of the uterus in milligrams to the body weight in grams is 2.5. Uterine hypertrophy may be observed within 48 hours after the injection of the substance containing theelin. Pregnancy urine caused uterine hypertrophy, but no hypertrophy followed injections of a preparation of the hormone of the anterior pituitary.

Attempted induction of labor by injections of theelin, J. T. WITHERSPOON (*Soc. Expt. Biol. and Med. Proc.*, 29 (1932), No. 9, pp. 1063, 1064).—Subcutaneous injections of theelin into eight pregnant negro women at full term were considered to be without effect, in the amounts given, in inducing labor.

Effects of X-rays in an inbred strain of guinea-pigs, H. H. STRANDOSKOV (*Jour. Expt. Zool.*, 63 (1932), No. 1, pp. 175–202, figs. 8).—The effects of X-ray treatments of from 2 to 30 minutes on the scrotal area of 85 closely inbred male guinea pigs are reported. Histological study of the testes showed that the treatment caused varying degrees of degeneration in the tubules, but in all cases a new functional epithelium was regenerated in less than 40 weeks. Studies of the semen samples produced by the ejaculation after electrical shocks showed that active sperm were not present for a certain period following X-ray treatment, but that duration of this period was related to the length of X-ray treatment.

In further study of the effect of the X-ray treatment, the treated males were each mated with two females. The litters sired by the X-rayed males averaged 2.04 ± 0.097 young as compared with 2.69 ± 0.079 for the controls. In addition to reducing litter size, the X-ray treatment increased the percentage born dead from 14.36 in the controls to 26.01 among the offspring of the treated males. The young raised to weaning were slightly lighter at birth in the group sired by treated males than in the control stock. The young of the treated males showed a small excess of males. The second and third generations following the treatment did not show effects which could be attributed to the X-ray treatments, and no visible mutations were observed.

FIELD CROPS

[Field crops experiments in Maine] (*Maine Sta. Bul.* 363 (1932), pp. 250–254, fig. 1).—Brief accounts are presented on the progress of experiments by J. B. Chucka and D. B. Lovejoy at Aroostook Farm, including comparisons of fertilizer formulas, carriers of phosphorus and of potash, “uncommon” elements and green manures, and a fertilizer placement study, all with potatoes; and variety tests with oats, barley, spring and winter wheat, rye, and flax for seed.

[Crops experiments in New Hampshire] (*New Hampshire Sta. Bul.* 270 (1933), pp. 6–8, 12).—Agronomic studies reported on briefly included a dairy farm rotation on neglected hay lands, a fertilized potato rotation, variety tests with soybeans, fertilizer tests with soybeans, sweetclover, and alfalfa, and a study of the effects of top-dressing old pastures, all by F. S. Prince, P. T. Blood, T. G. Phillips, and G. P. Percival; and control of poison ivy by applications of kainit, by O. Butler.

[Recent results of field crops research in Oregon] (*Oregon Sta. [Pamphlet, 1933]*, pp. 4–7, 12, fig. 1; *Branch Sta. [Pamphlets, 1933]*—*Harney Sta.*, pp. 4–6, 7, figs. 2; *Hood River Sta.*, p. 5; *John Jacob Astor Sta.*, pp. 3–5, figs. 3; *Pendleton Field Sta.*, pp. 1–3, figs. 5; *Sherman Sta.*, pp. 1–3, figs. 2; *Southern Oregon Sta.*, p. 5; *Umatilla Sta.*, pp. [4–6, 7, 8], figs. 3; *Oregon Livestock Sta.*, pp. 6–8, figs. 2).—Outstanding results obtained in experiments with field crops

(E.S.R., 64, p. 383) at the station and the Harney (Burns), Hood River, John Jacob Astor (Astoria), Pendleton, Sherman (Moro), Southern Oregon (Talent), Umatilla (Hermiston), and State Livestock (Union) Substations, often in cooperation with the U.S. Department of Agriculture, are reported in popular summaries. The work reviewed comprised variety trials with winter and spring wheat, oats for grain and hay, barley, rye, seed flax, field peas, vetch, alfalfa, sweetclover, miscellaneous grasses and forage legumes, potatoes, turnips, carrots, mangels, rutabagas, solling crops, and combinations for silage; trials of Jerusalem-artichokes; breeding work with wheat, barley, and oats; cultural experiments with alfalfa and sweetclover; seed production studies with alfalfa; hay measuring and weighing investigations; comparisons of seed bed preparation methods and of crop residues for wheat; soil moisture and nitrate studies; fertilizer trials with wheat, potatoes, and alfalfa; crop rotations; and control of quackgrass. Varieties of merit developed or introduced by the station are noted.

Yield and chemical composition of certain pasture crops, fertilized and unfertilized. M. S. GRUNDER (*Jour. Agr. Res. [U.S.], 46 (1933), No. 4, pp. 375-386*).—Italian ryegrass, a mixture of grasses and clovers for bottom land, and white clover, sown on untreated and on fertilized and limed plats on sandy soil at the Western Washington Experiment Station, were cut fortnightly during the 1930 growing season. A period of heavy production during May and June was followed by a constant drop in the production for the remainder of the season.

The total yields of dry matter per acre for the season of the different crops were for Italian ryegrass, fertilized 7,818.8 lb., unfertilized 6,041.8; bottom-land mixture, fertilized 7,618.8; unfertilized 6,522.4; and white clover, fertilized 6,604.1, unfertilized 5,314.2 lb. The respective percentages of crude protein for the season were 23.42, 23.17, 25.23, 26.28, 29.63 and 28.5.

Yields of dry matter and crude protein were usually higher through the season in the fertilized crops. The percentage of crude protein was maintained at a high level through the season by the cutting treatment, and tended to increase during the fall months. The presence or absence of clover seemed to exert a greater influence on the content of protein or calcium or the calcium-phosphorus ratios than did the fertilizer. The fiber, ether extract, and crude ash contents were consistently the higher in the fertilized crops. Under the conditions, the increased yield of dry matter was a more important result of fertilizer treatment than was any increase in protein, calcium, or phosphorus percentages.

Growing root crops for livestock. H. L. WESTOVER, H. A. SCHOET, and A. T. SEMPLE (*U.S. Dept. Agr., Farmers' Bul. 1699 (1933), pp. II+13, figs. 2*).—Cultural methods and harvesting practices involved in growing mangels, rutabagas, turnips, and carrots for livestock are outlined, together with information on varieties, storage methods, comparative composition, feeding the crops to cattle, sheep, horses, hogs, and poultry, production costs, yields, and insect pests and diseases.

Influence of light, temperature, and soil moisture on the hardening process in alfalfa. H. M. TYSDAL (*Jour. Agr. Res. [U.S.], 46 (1933), No. 6, pp. 483-515, figs. 10*).—The third of a series on hardiness in alfalfa (E.S.R., 67, p. 379), this paper, based on cooperative investigations between the U.S. Department of Agriculture and the Nebraska Experiment Station, deals with the influence of light, temperature, and soil moisture on the ability of different alfalfas to survive cold. Plants of Turkestan, Grimm, and Arizona common alfalfa, grown for 30 days in the warm greenhouse, served as the principal

material, and 14 days was the standard period in the hardening room. Equipment used was described earlier by Peltier (E.S.R., 66, p. 21).

The length of day was found to have a very important influence on the hardening process. The hardier varieties hardened off much more under a short day length than under a normal day length, but this response was confined to certain temperature ranges. Practically no response to a 7-hour day at 20° or at 0° C. was observed, but at 10° to 12° the response was very marked. Of the three varieties studied, Turkestan, the hardiest, responded most to the short day, and the unhardy, Arizona common, responded least. Intensity of light was also important in the hardening process, but only when the light reached a minimum beyond which a reduction caused a weakening of the plant. Above this minimum the response was not so marked as the response to day length. The short day at both medium and high temperatures greatly reduced growth, which was reflected in a high percentage survival of plants, at the medium but not at the high temperatures, indicating that reduced growth is not a criterion of hardening. Plants hardened under white light could withstand cold better than those hardened under red or blue light.

Resistance to freezing varied with the temperature at which plants were hardened. From 20° to about 0° the percentage survival increased as the temperature was lowered. Plants taken directly from a warm room to a hardening room at -5° were killed outright. At the range of optimum activity, light seemed to influence hardening almost as much as temperature, because for each hour of shortening in day length from a 10.5-hour day to a 7-hour day there was an increase in survival of 16, 6.3, and 1.4 percent for Turkestan, Grimm, and Arizona common, respectively, while for each 1° of decrease in the hardening temperature the increase in survival was 12, 10, and 6 percent.

Alternating temperatures during hardening markedly increased cold resistance, although this was influenced also by the time of day that plants were subjected to the cold and by the temperature of the hardening room. Indications were that alternating temperatures with light during the warm periods furnish the optimum conditions for hardening. Plants kept at 0° for 16 hours and then placed in a warm greenhouse (approximately 20°) during the day for 8 hours developed much greater hardiness than those kept continuously at 0°. This was true at all temperatures up to about 5° for Arizona common and 7° for Turkestan. Two or 4 hours in a hardening room at 3.8° also greatly increased the hardiness of the plants, the 4-hour plants being about equal in hardiness to those kept continuously at 3.8°.

A reduction in the soil moisture to as low as the incipient wilting point did not harden any of the varieties markedly, being often overshadowed by the rapidity and degree of freezing of the dry soil as compared to the moist soil. Plants in the moistest soil invariably gave the highest percentage of survival when frozen for the same length of time as the low-moisture set. If they were frozen until the soil temperatures in the two sets were the same, the survival slightly favored the plants hardened in the low-moisture soil. Plants kept severely wilted for 10 to 14 days and then frozen in the severely wilted condition were very much more resistant to cold than those watered normally. The close correlation between natural conditions in the fall, such as decreasing day length and alternating temperatures, and the effect on the hardening process of similar factors under controlled conditions is pointed out.

A statistical study of certain characters of the alfalfa plant concerned with seed production, B. DANN and L. R. WALDRON (*Jour. Amer. Soc. Agron.*, 25 (1933), No. 3, pp. 184-190).—In a statistical study at the North Dakota Experiment Station of data on characters of alfalfa plants grown in the Halle

(Germany) University garden, with four independent variables distinctly significant correlations were found between weight of seed per plant (dependent) and weight of plant, pods per racemes, and seeds per pod, for the zero, first, second, and third orders. Only total racemes was correlated positively and significantly with weight of plant for the various orders. As to the partial regression coefficients, a deviation of but 12 percent in plant weight accounted for a deviation of 10 percent in weight of seed per plant. A relatively enormous deviation of racemes per plant was required to result in a similar deviation of seed. The multiple correlation coefficient of the four independent variables on weight of seed per plant was 0.84.

The influence of the maturation environment upon the permeability of the seed-coat of barley, W. H. THARP (*Amer. Jour. Bot.*, 19 (1932), No. 10, p. 836).—Permeability studies were conducted at the University of Wisconsin with three hull-less and two hulled varieties of barley, grown under a natural relatively dry environment and under a field moist-cage where high soil moisture and humidity were maintained during maturation. A different rate of solute permeation was found for each variety tested. Samples matured under the moist-cage were more permeable than samples of the same barley matured in the drier condition, and grains harvested prematurely were more permeable than similar fully-matured kernels. These differences in relative permeability could not be correlated with any comparable variation in the anatomical structure of the seed-coat membranes. Microchemical tests failed to differentiate between the membranes from samples of barley exhibiting wide differences in rate of permeability.

The effect of seed inoculation and of a nitrogen fertilizer on the survival of red clover plants growing in soil previously treated with sodium chlorate, W. E. HAINES (*Jour. Amer. Soc. Agron.*, 25 (1933), No. 3, pp. 181-183).—Red clover seed sown in Minnesota Experiment Station studies at weekly intervals for 10 weeks in pots containing soil treated with sodium chlorate in solution survived best with inoculation and addition of ammonium sulfate, next best with inoculation alone, and the increase was lowest, yet significant, with ammonium sulfate alone. The percentage survival was considerably larger on untreated soil. With plants growing in chlorate-treated soil, there was a correlation of 0.65 ± 0.4 between the percentage of plants surviving from a treatment and the average nodules per plant on the plants surviving from the treatment.

The production and utilization of corn grown under irrigation in Washington, H. P. SINGLETON (*Washington Col. Sta. Bul.* 278 (1933), pp. 22).—Experiments with corn at the Irrigation Substation near Prosser showed that both early and late varieties have outyielded all small grains in the period 1922-32, and that both had greater feed value per ton. Late varieties, as Reid, Iodent, and certain local yellow strains surpassed early strains somewhat in yield, while Johnson County White and other very long-season varieties did not seem adapted for grain. Thayer Yellow and Windus White outyielded other early corns. Other tests and experience suggested planting as soon as frost danger is past; rows 36 to 42 in. apart for Reid and 36 in. or less for Thayer; drilling not closer than 14 to 16 in., nor checking more than 8 plants per hill; about 3 irrigations after planting on most soils and possibly 2 on heavy soils; and cultivation enough to control weeds. The comparative feeding values of eastern corn, local corn, and small grains and of silage have been noted earlier (*E.S.R.*, 52, pp. 672, 767; 66, pp. 359, 765).

Cotton experiments at the Lawton (Oklahoma) Field Station, 1910-1931, W. M. OSBORN (*Oklahoma Sta. Bul.* 209 (1933), pp. 31, *Agg.* 3).—Variety, date-of-planting, and spacing tests with cotton made in cooperation with the

U.S. Department of Agriculture are reviewed for the period 1916-31, and meteorological data are tabulated with remarks on the crops in the different years. Total seasonal precipitation was not so important as seasonal distribution; about 61 percent of the annual rainfall was received from April to September, inclusive.

While short-staple, early-maturing varieties produced slightly more lint than medium early cottons stapling $\frac{1}{8}$ to 1 in. and large-boll, late-maturing sorts with similar staple, the medium type was more desirable when yields, staple, storm resistance, fiber quality, lint percentage, and boll size were considered.

Plantings made May 1 and 15 returned highest average yields. Variety and season affected staple length and lint percentage more than did time of planting. Difficulty in obtaining a uniform stand from early plantings was not overcome by thick seeding.

Spacing single plants 18 in. apart in 44-in. rows produced highest average lint yields over 7 years. Two plants per hill returned somewhat lower yields regardless of spacing between plants or row width. Wide rows did not increase the lint yield. Thick spacing hastened maturity. The spacing had slight influence on the average lint percentage or staple length.

Development of the female gametophyte and embryo in cotton, U. R. GORE (*Amer. Jour. Bot.* 19 (1932), No. 10, pp. 795-807, pls. 2).—The development of the female gametophyte and early stages of embryo development were studied in Sea Island, Pima Egyptian, and upland cottons of the Delfos 6102 and Mebane varieties at the Texas A. and M. college.

The embryo sac was observed to develop from the chalazal megaspore of the tetrad, the complete structure being very long and embedded in many layers of nucellus. The antipodals degenerate early, and the polar nuclei begin fusing before entrance of the male gametes to form a polar fusion nucleus. The pollen tube enters the ovule 15 to 20 hours after pollination, and by digesting its way through the nucellus reaches the embryo sac. Slight branching of the tube in the region of the integuments was noted. Fertilization is completed from 24 to 30 hours after opening of the flower. The endosperm in cotton usually results from the fusion of the second male gamete with the polar fusion nucleus. Various methods of triple fusion are reported. A massive endosperm is developed only to be resorbed by the growing embryo. The embryo develops a short suspensor.

Fiber abnormalities and pressure variations within the boll in *Gossypium*, W. K. FARR (*Amer. Jour. Bot.*, 19 (1932), No. 10, p. 839).—Pima Egyptian and Super Seven and Acala upland cottons showed increasing numbers of fiber abnormalities in the order named and in the ratios of 15:90:170. Very few abnormalities occurred before the twentieth day from fertilization in any one of the cottons. Measurements during the entire period of development indicated that pressure within the boll is relatively small in Pima, moderate in Super Seven, and large in Acala, and that it increases from the twentieth day until near dehiscence. The possibility was suggested that pressure may be an important factor in the formation of fiber abnormalities.

Root development of cotton plants in the San Joaquin Valley of California, J. W. HUBBARD and F. W. HERBERT (*U.S. Dept. Agr. Circ.* 262 (1933), pp. 8, figs. 5).—Records of cotton root development made under field conditions at Shafter, Calif., in 1929 and 1930 showed that cotton seedlings establish deep root systems promptly, indicating that irrigation is seldom necessary until long after planting. Plants 8 to 10 in. high and with 8 to 10 true leaves had taproots extending 50 to 60 in. below the soil surface, and even small seedlings in the cotyledon stage without true leaves had roots down 12 to 16 in. Streaks of coarse sand wherever encountered interfered with root penetration, the roots

often ending abruptly after going only a few inches into the sand, the tips having perished. Many large lateral roots developed near the soil surface on plants irrigated early in the season, while very few or no lateral roots developed near the surface on unirrigated plants. Deep penetration of roots in early growth stages appears desirable, since it affords a more constant condition for plant development.

The relation of size and shape of plant to the yield of cotton, S. N. VENKATRAMAN and C. J. RAO (*Madras Agr. Jour.*, 21 (1933), No. 2, pp. 51-58, figs. 5).—The relation of height, nodes, and number of monopodia to the yield of cotton was studied in 6,000 plants, the progeny of 46 selections of Northern cotton (*Gossypium indicum*).

In plants of the same strain, number of monopodia and plant height were correlated markedly with yield, whereas the genetic relation from strain to strain was different. While taller types were not necessarily good yielders, strains with more monopodia were more productive. The number of nodes was not of much significance toward yield, either within or between strains. The correlation of yield to other characters was significantly greater in normal plants than in those attacked by the shoot borer (*Borassia* sp.). Study of the regression of plant yield on these characters showed that the relation of monopodia and, to a large extent, of height was rectilinear, indicating a proportionate increase of yield with increase in these characters. Examination of yield from plants in all strains showed attacked plants to give a significantly higher yield, this increase being associated with an increase in number of monopodia per plant and in an increased rate of productivity per monopodium. A comparison of other strains, as Cambodia and particularly Uppam (*G. herbaceum*), where the effect of the borer was the reverse, showed the difference in behavior could be attributed to the more monopodial habit of this type. The relation of yield to monopodia was much higher in this cotton than in more sympodial types.

Community production of cotton in relation to yield and staple length, J. A. SHANKLIN, R. C. CAMPBELL, and W. C. JENSEN (*South Carolina Sta. Circ.* 48 (1933), pp. 26, figs. 6).—The influence of the source and care of cottonseed for planting on the yield and length of staple produced was studied in communities in Orangeburg, Marlboro, Chesterfield, and Pickens Counties, S.C., in cooperation with the U.S. Department of Agriculture.

Most of the cotton produced in the four communities was grown on Norfolk, Portsmouth, and Marlboro sandy loams, Johnson loam, Cecil sandy clay loam, and Georgeville clay loam. Each community produced cotton as the chief money crop, and the soils in each community are considered ideal for cotton production. The 329 growers included 91 growers of cotton from pure seed of improved varieties, 77 of cotton from mixed seed of improved varieties, 130 of run-down short staple cotton, and 31 producers of long staple cotton. The total production was 5,139.6 bales on 8,758 acres.

The yield of lint per acre from pure seed of improved cotton averaged 349.4 lb., compared with 294.9 lb. for cotton produced from mixed seed of improved varieties and 263.3 lb. for the run-down short staple varieties. Only 5.8 percent of the total acreage was long staple cotton, and only two communities produced this type, but the long staple cotton outyielded the run-down short staple group by a few pounds to the acre. Of the cotton from pure seed 73.7 percent stapled 1 in. or longer as compared with 76.9 percent for mixed seed of improved varieties. No untenderable cotton was produced from pure seed, and only 1.9 percent of the cotton from mixed seed was classed untenderable. In the run-down short staple group only 3.3 percent of the cotton was 1 in. or longer, while 26.9 percent of the lint was untenderable. Of the long staple cotton, 96.9 percent was $1\frac{1}{2}$ in. or longer. In all communities the pure seed of

improved varieties produced the highest yield per acre. No data collected justified the planting of run-down short staple varieties, for they are the lowest yielders and also have a much shorter staple.

Mechanical application of fertilizers to cotton in South Carolina, 1931. G. A. CUMINGS, A. L. MEHRING, J. J. SKINNER, and W. H. SACHS (*U.S. Dept. Agr. Circ. 264* (1933), pp. 32, figs. 15).—Experiments on methods of applying fertilizers to cotton in South Carolina (E.S.R., 66, p. 427) were continued under similar cooperation on Norfolk very fine sandy loam at the Pee Dee Substation, on Norfolk coarse sand at the Sandhill Substation, and on Cecil sandy clay loam at Clemson College.

Under conditions prevailing in 1931, 800 lb. per acre of 4-8-4 fertilizer drilled either in bands 1.5 or more inches to each side or 4 in. directly below the seed apparently did not affect germination injuriously. On Cecil sandy clay loam the appearance of seedlings was delayed greatly and the final stand was reduced seriously only when all the fertilizer was placed in contact with the seed, but on Norfolk coarse sand and Norfolk very fine sandy loam this happened also when the fertilizer was placed below the seed either in bands at depths of 3 in. or less when mixed with the soil and when one eighth or one fourth of the fertilizer was placed in contact with the seed.

The movements of soluble salts in the sandy soils from the original position of the fertilizer into the seed zone during the germination period were insignificant from placements at the sides, although serious from placements directly below the seed. The degree of delay or injury to germination was related closely to the amount of soluble salt carried into contact with the seed. The seedlings came up most rapidly when the method of application produced in contact with the seed a soil solution containing between 0.05 and 0.2 percent of soluble salts. As the concentration rose from 1 to 3 percent, fewer and fewer plants came up, and when the solution contained 3 percent or more no plants came up. Soluble salts spread farther from the point of application in the coarse sand than in the sandy clay loam.

Highest cotton yields were obtained with side placements on the sandy soils, while on the clay loam with heavy rainfall during germination, the most seed cotton was obtained with bands placed 1 in. below the seed, although good yields were also made with side placements. No advantage was gained either in mixing the normal amount of fertilizer with soil or in placing one eighth or one fourth of the application in contact with the seed and the remainder at the sides or below the seed.

Equivalent quantities of the 4-8-4 and 8-16-8 fertilizers produced similar results. On the sandy clay loam where the final stand was good, increase in the application rate of the 8-16-8 fertilizer from 200 to 400 and 600 lb. per acre gave higher yields for the three representative placements, but on the very fine sandy loam and coarse sand increased yields were made only when fertilizer was placed in bands 3.5 in. to each side and 2 in. below the seed level. On sandy soils, when the fertilizer was placed below the seed or mixed with the soil the consequent reduction of stand gave lower yields.

Hard seed in Korean lespedeza, G. K. MIDDLETON (*Jour. Amer. Soc. Agron.*, 25 (1933), No. 2, pp. 119-122, fig. 1).—Germination tests on well-matured Korean lespedeza seed, made by the North Carolina State Department of Agriculture at monthly intervals from November 1931, through March, 1932, showed a rapid decrease in hard-seed content and a corresponding increase in germination for each sample from November through January, but with very little further change by March. The average percentages of hard seed were for November, 47.25; January, 12.25; and March, 11.05; and of germination were 46.7, 83.3, and 84.55, respectively. The conclusion that for satisfactory results germina-

tion tests should be delayed at least until January following harvest was substantiated by numerous tests during three years. With tests made early in the season, the total viable seed content seemed to be a more reliable guide to agricultural value than is germination alone. For well-matured, bright, plump seed, deduction of 15 percent from this total, as determined in the fall, proved a safe estimate of the actual germination obtained the next spring.

Size of Korean lespedeza seed in relation to germination and hard seed. G. K. MIDDLETON (*Jour. Amer. Soc. Agron.*, 25 (1933), No. 3, pp. 173-177, fig. 1).—Germination tests on samples of Korean lespedeza seed, separated into different sizes by screens, showed a definite relationship between size of seed and hardness. The smaller seed had the higher percentage of hard seed, and seed intermediate in size was intermediate in this respect. In the samples used maturity did not obscure the relationship existing between size and hardness. It seemed that where second-grade seed are to be used, field tests should be delayed as late as possible, and the seeding rate based on actual germination. The data presented are not in conflict with those noted above.

Natural crossing with wild oats, *Avena fatua*. R. A. DERICK (*Sci. Agr.*, 13 (1933), No. 7, pp. 458, 459).—Natural crossing amounting to 0.1 percent was obtained at the Ottawa farm when small blocks of *A. fatua* were sown in the midst of a larger block of *A. fatua*. The prevailing west wind caused considerably more natural crossing than the north wind, while east and south winds had no effect.

Studies of potato storage. O. SMITH (*New York Cornell Sta. Bul.* 553 (1933), pp. 57, figs. 23).—Studies were made on the influence of the stage of maturity of the tubers at time of harvest; careful harvesting and handling methods; storage temperature and humidity for a brief period immediately after digging; and temperature, humidity, and evaporating power of the air during storage, on the physiological and decay loss in weight of potatoes, the respiration rate of the tubers, and the rapidity and extent of suberization and wound-periderm formation. Other studies dealt with the portion of the storage period in which tubers lose the most weight; the effect of depth of piling on loss in weight and on temperature, composition, and evaporating power of the air within the bin of potatoes; and the amount of shrinkage of potatoes in several types of commercial storage houses. The experiments were carried on in two potato-storage houses at Ithaca, N.Y., and five houses of various types located within 50 miles of Ithaca, during the years 1929-32.

The greatest shrinkage losses of potatoes were observed to occur during the first and sixth and seventh months of storage. Shrinkage during the first month appears to be due largely to excessive evaporation and high rate of respiration through injured and uncorked surfaces of the tuber, whereas the increase in loss during the last two months occurred simultaneously with excessive sprout growth and increase in temperature. The shrinkage in weight of tubers and the water loss from an atmometer are very similar during the first month and the last two months of storage when the tubers are in an active condition. During the second to fifth months, inclusive, when the tubers are in a resting state, the rate of loss of water from the atmometer is more rapid than the loss from the tubers.

The highest rate of respiration of the tubers was found to occur just after harvest. The rate decreases rapidly even if the tubers are placed at a comparatively high temperature, but again increases with resumption of growth after the dormant period. The greatest rate of respiration occurred in immature tubers harvested in the normal manner, and the least occurred in mature, carefully harvested tubers. The loss in weight due to loss of carbon dioxide in respiration was very small compared with the loss caused by

evaporation of water. Immature tubers lost more weight during the first five months of storage than mature tubers. Indications were that beyond this period mature tubers may lose more weight if they terminate dormancy earlier and sprout more extensively than the immature tubers.

The effect of the temperature at which tubers were held for a short time just after harvesting on the physiological and decay loss of tubers was very marked. Tubers stored from 8 to 12 days at 63° to 68° F. lost considerably less weight and decayed less in subsequent storage than those stored at 39° to 44°. Suberization first made its appearance on the second day and wound periderm on the third day in tubers stored at 68°, whereas suberization was not detected until the sixth day in tubers at the 40° storage, and no periderm layer was noted at the end of 12 days. Such delay in wound healing seemed to offer greater possibilities for loss in weight of injured tubers and increased tuber decay.

Potatoes harvested with a padded digger and picked up in padded containers had much lower shrinkage and decay losses during storage than tubers harvested and handled in the normal manner. Mechanical injuries to tubers also caused greater losses in respiration.

Study of the evaporating power of the air at different levels within a bin of potatoes showed the greatest loss of water from atmometers in the bottom layer and the least from the middle layer, which, however, was exceeded only slightly by the atmometers in the top layer. The smallest shrinkage losses occurred in the tubers of the middle portion of the bin. When the tubers were removed early in the season, before extensive sprouting, the greatest loss occurred in the bottom layer, but in the top layer when tubers were removed late and sprout growth was large. Sprout growth was more extensive in the top layer than in the middle or bottom layers. The evaporating power of the air surrounding the bin exceeded that of the air in any part of the bin when surrounded by potatoes. The average temperature near the floor of the bin for the storage season approximated 5° lower than on top of the bin of potatoes, and the air within the bin averaged 2° to 9.5° higher than the air surrounding the bin. A slightly higher percentage of carbon dioxide was found in the lower layer than in the middle or top layers, due possibly to any or all of greater respiratory activity, inability of gases to escape, or accumulation from layers above due to density of the gas. The analyses indicated that ventilation to replenish the air to increase the oxygen or to decrease the carbon dioxide percentage is unnecessary.

Slightly larger physiological losses in weight of tubers occurred in slatted than in solid-sided bins, while there was no consistent difference in shrinkage of the tubers in insulated and uninsulated cellar rooms.

During three years the greatest physiological loss in weight of potatoes occurred in a house-cellar storage, and the next greatest losses in a barn basement and bank storages, respectively. In most of the storage studies a positive relation was shown between low shrinkage losses of potatoes and high average relative humidity, low average temperature, and low evaporating power of the air surrounding the bin.

Dictionary of sugar terms in 12 languages, R SHEMENESKY (*Lexique des Termes Sucriers en 12 Langues*. [Paris: La Betterave], 1931, pp. 360).—This book gives the French equivalents and vice versa of important laboratory, technological, mechanical, and agricultural terms of the sugar industry for German, English, Spanish, Hungarian, Italian, Dutch, Polish, Portuguese, Russian, Swedish, and Czech; the nomenclature of cane sugar and machinery in Spanish and English; and includes tables of weights and measures, weights of materials, and engineering constants.

Methods of producing sugar-beet seed in southern New Mexico, H. A. ELOOCK and J. C. OVERPECK (*New Mexico Sta. Bul.* 207 (1933), pp. 29, figs. 7).—Practices recommended tentatively for growing sugar beet seed in southern New Mexico, including soil selection, crop sequence, preparation, cultural, irrigation, and harvesting practices—threshing and cleaning, are based on experiments (*E.S.R.*, 65, p. 36) since 1922 in cooperation with the U.S. Department of Agriculture and experience with commercial plantings. Trade requirements for sugar beet seed, seed testing, control of insect pests, undesirable cross-pollination, and the outlook for the industry are also discussed briefly.

Persistence of viability of sweet clover seed in a cultivated soil, T. E. STOA (*Jour. Amer. Soc. Agron.*, 25 (1933), No. 3, pp. 177-181, figs. 3).—Following sweetclover trials at the North Dakota Experiment Station in 1918, in which seed was allowed to mature, volunteer seedlings from seed becoming permeable were more or less in evidence every year including 1932, in spite of the cropping method in each year which resulted in the early destruction of all volunteer sweetclover. The same characteristic preservation of seed was noted on other fields of the station. The sweetclover seed content of soil samples taken in different years was determined. The possibility is suggested that such behavior of sweetclover may be one factor upsetting the uniformity of experimental soil and influencing experimental results.

Distinctive effects of the deficiency of certain essential elements on the growth of tobacco plants in solution cultures, J. E. McMURTRY, JR. (*U.S. Dept. Agr., Tech. Bul.* 340 (1933), pp. 43, pl. 1, figs. 12).—Distinctive deficiency effects of N, P, K, Mg, Ca, B, S, Fe, and Mn on the Connecticut Broadleaf tobacco plant, as produced in a series of nutrient solutions so devised as to permit the withholding of each essential element as desired without changing the quantities of other elements present, are described and illustrated.

Deficiency of nitrogen is shown by the whole plant assuming a light green color, with more or less yellowing and drying or firing of the lower leaves to a light brown color. Shortage of phosphorus produces a dark green plant which may show some yellowing and drying of the lower leaves to a greenish brown. Lack of potassium and magnesium is shown by localized effects, especially chlorosis of the lower leaves. Typical potassium hunger is distinguished from magnesium hunger by the small necrotic spots or specks at the tip and margins of the chlorotic leaves. The chlorotic areas in potassium hunger are yellowish, and with magnesium hunger are pale green or white, with the principal veins tending to retain the green color in both cases.

The deficiencies noted above are general or occur on the older or lower leaves, while those of iron, manganese, sulfur, calcium, and boron show themselves typically on the new growth or bud leaves. Deficiency of iron, manganese, or sulfur produces chlorosis of the younger leaves, each of a characteristic type. Iron chlorosis and manganese chlorosis resemble each other in that the veins tend to retain their green color, but lack of manganese results in a necrotic spotting scattered over the leaf, while no necrotic spots occur with iron deficiency. In chlorosis resulting from sulfur deficiency, the veins are of a lighter green color than the tissue between the veins.

A lack of calcium first becomes apparent as a peculiar hooking downward of the tip of the young leaves of the bud, followed by a breaking down at their tips and margins, which show a cut-out appearance if later growth takes place. Boron shortage is shown in a light green color at the base of the young leaves of the bud, followed by their breakdown which, if not too severe, is followed by later growth, causing the young leaves to become distorted or twisted at their bases. Usually the tip of the leaf remains alive for some time after the base has broken down.

Typical reactions of the roots to the several deficiencies are described, and a key to the deficiency effects studied, based on the contrasts noted, is included.

The possible effect of hydrogen-ion concentration on the absorption of potassium and phosphorus by wheat plants under field conditions, J. DAVIDSON (*Jour. Agr. Res.* [U.S.], 46 (1933), No. 5, pp. 449-453).—Wheat grown on a field plot treated with sodium nitrate at the rate of 600 lb. per acre and on a controlled plot was sampled for analyses at frequent intervals up to maturity. The potassium and phosphorus contents of the entire plant in early growth stages, and of the stalks alone in later stages, showed that potassium was consistently higher in all samplings from the treated plot than in samplings from the control, whereas the reverse was true in the case of phosphorus. The results were considered analogous to those previously reported (E.S.R., 58, p. 213) from water cultures with controlled H-ion concentration, and seemed to be explained by a possible change in the H-ion concentration of the soil caused by the sodium nitrate, a physiologically alkaline fertilizer.

An hypothesis previously advanced explaining the accumulation of cations and anions in growing plants based on the isoelectric relations of the ampholytes of the living cell is discussed further.

Germination of the seed of farm crops in Colorado after storage for various periods of years, D. W. ROBERTSON and A. M. LUTE (*Jour. Agr. Res.* [U.S.], 46 (1933), No. 5, pp. 455-462).—Seed of different cereals adapted to Colorado, stored for varying periods (1920-29) in a dry room at the Colorado Experiment Station, were subjected to annual germination tests.

No connection was evident between the average annual relative humidity and the original germination percentage. Humidities for all years were low. The general trend seemed to indicate that oats, covered barley, and Marquis and Kanred wheat have a high percentage of germination the first year, while Kubanka wheat, Nepal barley (naked), and rye were comparatively low in this respect.

The germination percentage of wheat decreased about 7 percent in 10 years, of barley about 14 percent, and of both midseason and early oats about 13 percent. Two-row and naked barley decreased more than hulled 6-row barley. Rosen rye and Wisconsin Black soybeans decreased 10 percent in germination in 5 years and rapidly thereafter. Black Amber sorghum germinated well for 6 years, decreasing only 2 percent. Yellow dent corn germinated well for the first 4 years, but decreased 13 percent in the fifth year and 20 percent after 8 years of storage.

The microphotography [of the seeds] of cereals and legumes [trans. title], D. STRILCIUC (*Ztschr. Gesam. Getreidew.*, 17 (1930), Nos. 8, pp. 176-181; 9, pp. 194-196, pls. 4; 10, pp. 213, 214, pls. 4; 11, pp. 232-234, pls. 4; 12, pp. 254, 255, pls. 4).—Microphotographs show the cell structure of the principal parts of the mature kernels of the several cereal grains, sorghum, millet, and buckwheat, and of the seed of important legumes usually used for food purposes.

Seed inspection, F. A. McLAUGHLIN and M. E. NAGLE (*Massachusetts Sta. Control Ser. Bul.* 67 (1933), pp. 47).—The germination, purity, and weed seed contents are tabulated for 463 official samples of agricultural seed collected in Massachusetts during the year ended October 1, 1932. Samples of sweet corn, alfalfa, red clover, and sweetclover were also tested for trueness to type, and factors affecting the germination and vigor of garden peas were studied.

Results of seed and legume inoculant inspection for 1932, J. G. FISKE (*New Jersey Sta. Bul.* 550 (1933), pp. 87).—The germination percentage, purity, and other information are tabulated for 1,503 official samples of seed of field crops, vegetables, and lawn mixtures obtained from dealers in New Jersey

in 1932, and the crops, inoculation, number of organisms, and viability are shown for 63 official samples of legume inoculants.

Leafy spurge, life history and habits. H. C. HANSON and V. E. RUDD (*North Dakota Sta. Bul. 266 (1933), pp. 24, figs. 21*).—The distribution, characteristics, life history, and growth habits of leafy spurge (*Euphorbia virgata*) are described in some detail, with brief accounts of studies of dissemination, seed germination, and control.

Leafy spurge, a perennial herb containing latex in all its organs and occurring in fields, pastures, roadsides, and in waste areas, is widely distributed in northern United States and occurs in Canada. Its root system is well developed, going down to an 8-ft. water table in heavy clay soil and with a maximum lateral spread of 3.5 ft. It spreads readily by seeds and roots. Seed germination ranged from 50 to 80 percent in the laboratory and was about 70 percent in the field.

Pieces of roots as small as $\frac{1}{2}$ in. long and about $\frac{1}{8}$ in. in diameter produced new shoots which grew very rapidly. Pieces of roots, 3 in. long by $\frac{1}{4}$ in. in diameter, produced new shoots from at least 6 in. deep. Small or large pieces of the roots withstood up to from 2 to 3 hours of drying in the hot sun before they were killed.

Control experiments indicated that the weed may be killed by sodium chlorate applications, at least from 6 to 8 lb. per square rod being necessary, and also by common salt, or by frequent cultivation during two seasons.

HORTICULTURE

[**Horticulture at the Maine Station**], J. A. CHUCKA, D. B. LOVEJOY, R. M. BAILEY, I. M. BURGESS, F. B. CHANDLER, I. C. MASON, and C. R. PHIPPS (*Maine Sta. Bul. 363 (1932), pp. 254-264, figs. 4*).—Data are presented on various projects, including a study of the yield of peas and dry vines of the Surprise and Perfection varieties; the results of sweet corn and bean fertilizer and liming tests; the progress of breeding, pollination, and selection studies with apples; small fruit variety tests; variety and strain tests of sweet corn, field beans, and various garden vegetables; and fertilizer, selection, pollination, propagation, and cultural experiments with blueberries.

[**Horticulture at the New Hampshire Station**] (*New Hampshire Sta. Bul. 270 (1933), pp. 14-19*).—In condensed form reports are given on the results of a study of three different methods of pruning apple trees, on the fertilizer requirements of apples in sod and in cultivation, and the fertilizer needs of the peach, all by G. F. Potter; cold storage of McIntosh, Baldwin, and Cortland apples, including its effect on railroad worm larvae, and scab, by E. J. Rasmussen; the effect of storage delay in reducing brown core; pollination of McIntosh apples, by L. P. Latimer; the influence of phosphorus on fruit bud formation in the apple, by Potter; the use of electrically heated hotbeds, growth of tomatoes in sand, thinning and fertilizer needs of the squash, time of planting cabbage, and variety testing of vegetables, all by J. R. Hepler; and fruit varietal trials and fertilizers for strawberries, both by Latimer.

[**Horticultural investigations in Oregon**] (*Oregon Sta. [Pamphlet, 1933], pp. 7-9; Branch Sta. [Pamphlets, 1933]—Hood River Sta., pp. 5, 6, 7, figs. 2; Southern Oregon Sta., pp. 2-4, 5-7, figs. 4*).—Brief reports are presented on the results of studies of outstanding significance at the main station in the development of machinery and methods for removing spray residues; small fruit breeding; disease and insect pest control; irrigation of bramble fruits, etc.; at the Hood River Substation on the use of cover crops and irrigation and other factors in orchard management; pollination of pears; and fertilizer requirements of

tree fruits and strawberries; and at the Southern Oregon Substation on pear production problems, including the development of pear stocks; the use of Bordeaux mixture spray in blossom blight prevention; pollination of pears; and control of miscellaneous troubles, such as leaf burn, little leaf, Bosc edema, etc.

The Medford Branch Experiment Station (Oregon Sta., Medford Branch Sta. [Pamphlet, 1933], pp. [6], figs. 4).—This leaflet outlines briefly the problems confronting and projects under way at the new branch station established near the city of Medford, Oreg., in the heart of an important pear-producing district, to specialize in pear irrigation.

Relation of hydrophilic colloids to hardness in cabbage, brussels sprouts, and alfalfa plants as shown by the dye adsorption test, S. DUNN (Plant Physiol., 8 (1933), No. 2, pp. 275-286, figs. 3).—Having suggested in an earlier paper (E.S.R., 64, p. 37) that the dye adsorption test when used alone is not sufficiently consistent to give conclusive readings upon the hardness of apples, the author herein presents the results of similar trials with other plants grown mostly in the greenhouses of the New Hampshire Experiment Station. Random tests on cabbage plants hardened for varying periods showed, on the average, that hardness as indicated by the dye adsorption test increased up to 5 days of hardening. In general the results agreed with those of parallel freezing tests. Tests on cabbage and brussels sprouts in which actual frost resistance was first determined showed that where this could be accurately determined there was usually a greater amount of dye adsorbed from solution than in the case of less hardy plants.

Adsorption tests with different dyes varying somewhat in their adsorptive action indicated (1) that pectic substances may be partly responsible for cold resistance, (2) that lignin and allied substances and perhaps proteins are converted during the hardening process, and (3) that constituents of the protoplasm rather than of the cell walls are of primary importance in hardness.

In the case of alfalfa, dye adsorption of macerated roots was greater in the harder plants. It is believed that the conflicting results obtained with apple tissue may have been due to the relatively small proportion of vital tissue in relation to the total bulk of the twigs.

Cabbage characters and their heredity, I. R. DETJEN and C. A. McCUX (Delaware Sta. Bul. 180 (1933), pp. 147, pls. 16, figs. 4).—In summing up results of long continued breeding experiments discussed from time to time in the annual reports of the station (E.S.R., 66, p. 533), the authors state that cabbage characters pertaining to the plant as a whole or to certain attributes of the head depend frequently on a combination of factors commonly designated as multiple factors. Incompatibility in cabbage is said to be governed in the main by a series of multiple factors which result in a manifestation of very distinct types. Environmental factors, such as temperature, may, however, affect seed setting and temporarily mask the genetic factors. The inheritance of heading, a most important character in cabbage, was studied in various crosses and selfings. Heading plants crossed with headless forms which had been derived from heading varieties produced fully headed plants in the F₁ generation. Heading was likewise found to be governed by a multiple factor for season, which was not allelomorphic to the early factor, although some interference was observed. The type of inflorescence was also based on a multiple factor.

Other characters discussed include color of the leaves, fasciation of stems, length and diameter of stems, length and smoothness of seed pods, savoying of the leaves, etc.

Further evidence that boron is essential for the growth of lettuce, J. S. McHARGUE and R. K. CALFEE (*Plant Physiol.*, 8 (1933), No. 2, pp. 305-313, figs. 8).—In this contribution from the Kentucky Experiment Station there is described a deficiency disease of lettuce resulting from an insufficiency of boron. The first symptoms of deficiency were retarded growth and malformation of the younger leaves, followed by a gradual destruction of the meristematic tissues and the ultimate death of the plant. Small quantities of boric acid, powdered Pyrex glass, and borates of potassium, sodium, calcium, manganese, copper, and zinc were found effective in preventing injury. Plants grown in a boron concentrate of 0.4 p.p.m. were free from leaf injury but produced only a few seeds. Between 0.4 and 0.9 p.p.m. there occurred vigorous growth and normal development, with no evidence of toxicity or boron deficiency. The concentration of 1.2 p.p.m. was decidedly toxic, causing chlorosis and death of the older leaves, and quantities above 2.5 p.p.m. were fatal. Borosilicate was found the most satisfactory compound for incorporation in sand cultures.

Relation of hydrogen-ion concentration to the growth of onions, A. L. WILSON (*New York Cornell Sta. Mem.* 145 (1932), pp. 59, figs. 20).—The optimum H-ion concentration for the growth of onions cultured in nutrient solutions in an acidity range of pH 3.5 to 8 by half degree intervals was determined in three separate experiments conducted under diverse conditions of light, length of day, and temperature. The three experiments failed to show a common optimum value for maximum growth, a result which, from the author's viewpoint, might well be accounted for by the existing environmental differences; for example, the three experiments were initiated on March 12, June 12, and January 4, respectively. The maximum percentage increase in growth was obtained at pH 6.5 to 7, 5.5, and 5.5 to 7, respectively. From the data the author concludes that onions grow well over a pH range of from 5.5 to 7 when other environmental conditions are favorable.

The first injury due to H-ion or OH-ion concentration was observed in the roots. At pH 3.5, 4, 4.5, 5, and 8 subsequent injury occurred in the tops and most of the leaves died. At pH 3.5 all the roots died, and there was much loss of roots at pH 4 and 4.5. Lateral root development was inhibited at high concentrations of both H ions and OH ions. In some cases laterals were killed at about the time they penetrated the epidermis, and in other cases they grew to be from 1 to 2 mm long, when their tips died leaving a cluster of lateral stumps. Although many theories have been formulated to account for the injurious effects of acidity and alkalinity on plants, the author believes the real causes are unknown.

Composition of rhubarb at different stages of maturity in relation to its use in cooking and canning, C. W. CULPEPPER and H. H. MOON (*Jour. Agr. Res.* [U.S.], 46 (1933), No. 5, pp. 387-402, figs. 6).—In this second report (E.S.R., 67, p. 676) on a study conducted at Arlington Experiment Farm, Va., it is stated that total solids were high in very young petioles, decreased while the petioles were elongating most rapidly, increased again during the period of maximum photosynthetic activity, and finally decreased somewhat in the very old material. Titratable acidity did not vary greatly until petioles were old, when a sharp decrease occurred. With both solids and acidity the season of year had a marked effect, the July and October samples being higher in solids and acids than were the spring samples. Sugars and acid hydrolyzable polysaccharides were very low and rather constant. Total nitrogen and amino nitrogen were highest in young leaves, whereas nitrate nitrogen increased with age. Pectin-

like materials, considered largely protopectin, were present in the petioles and apparently had considerable influence on cooking quality.

Packing rhubarb in reenameled, high-grade tins lessened corrosion and improved the flavor as compared with the product stored in plain tin cans. Nitrates, oxalic acid, and malic acid are believed involved in corrosion. If petioles at the proper stage of maturity are selected it is believed that rhubarb may be cooked or canned to advantage at any time during the growing period.

New or noteworthy fruits, XI, G. H. Howe (*New York State Sta. Bul. 620* (1933), pp. 18, pl. 1).—Briefly summarizing the work of the station in the testing and recommending of new and promising fruits, the author in this, the eleventh of a series (E.S.R., 62, p. 733), discusses and describes the Kendall apple, the Ovid and Willard pears, the Early Rivers and Emperor Francis cherries, the Oriole and Vallant peaches, the Seneca grape, the Naples black raspberry, and the Cato, Clermont, and Culver strawberries. The Kendall apple is shown in color.

Notes on the species of apples.—I, The American crabapples, G. P. VAN ESSELTINE (*New York State Sta. Tech. Bul. 208* (1933), pp. 22, figs. 9).—Accompanied by drawings of the dissected flowers, a review is presented of American species and varieties of *Malus*, section *Chloromeles* and subsection *Fuscae* of section *Sorbomalus*. Two new names are offered, namely, subsection *Fuscae* n. subsect. and *M. angustifolia puberula* n. comb. In the case of the eastern American crab apples it is recommended that they be grafted on seedlings of the wild sweet crab or the prairie crab, as the trees live much longer than when on roots of the common cultivated apples. Among varieties derived from *M. ioensis* is the well-known double-flowered ornamental Bechtel crab.

Experiments with commercial nitrogenous fertilizers on apple orchards, J. D. HARLAN and R. C. COLLISON (*New York State Sta. Bul. 623* (1933), pp. 36, fig. 1).—Experiments conducted in six western New York apple orchards, two of Baldwin, two of McIntosh, one of Rome Beauty, and one of Rhode Island Greening, showed that carriers such as nitrate of soda, calcium nitrate, and ammonium sulfate having their nitrogen in readily available form invariably gave good results. Early spring applications produced larger yields than did summer applications, and the application of nitrate of soda after bloom did not result in yields significantly higher or lower than those obtained from early spring applications. The use of nitrogen in the on or heavy blooming year had no significant effect on subsequent yields as compared with those secured from fertilizing annually. Very little evidence was secured that a complete fertilizer containing nitrogen, phosphorus, and potash increased yields above those obtained from the use of nitrogen alone.

With relation to quantity in the early spring applications, 12 lb. of nitrate of soda per each Rhode Island Greening tree increased yields above the 6-lb. treatment. Similar results were secured with McIntosh apples, but decreased color followed the larger applications. In the case of Rome Beauty 7.5 lb. of nitrate of soda or its equivalent in more concentrated materials did not increase yields above those secured with 5 lb.

As to quality of materials the largest and most consistent yields were secured from nitrate of soda, calcium nitrate, and ammonium sulfate. The authors concede, however, that on heavier soils and on those soils containing supplies of organic matter where cultivation or other means of hastening nitrification can be made effective the use of calcium cyanamide, urea, and Calurea should prove satisfactory in producing increased apple yields on healthy trees in well-drained soils.

Progressive changes in the cuticle of apples during growth and storage. K. S. MARKLEY and C. E. SANDO (*Jour. Agr. Res. [U.S.]*, 46 (1933), No. 5, pp. 403-412).—Following an earlier study (E.S.R., 65, p. 739) which dealt largely with fruit grown at Arlington Experiment Farm, Va., apples were secured from the Wenatchee Valley, Wash., and from western New York. Conforming with earlier results, it was found that in fruit from both origins the quantities of ursolic acid, oily fraction, and total ether extract present at maturity and at the end of the storage period were greater than those found in the early stage of growth, and that the quantities of these constituents increased from the time of picking to the end of the storage period. With advancing maturity there was generally a progressive increase in the percentage of the oily fraction in the total ether extract.

Using a specially devised method for the quantitative determination of cutin, it was found that this material was more abundant at maturity and at the end of the storage period than in the early stages. Based on averages of mature fruits of several varieties, the ratio of total ether extract to cutin was about 44:56, indicating that the cuticle of apples is composed of approximately 44 percent of ether-soluble constituents and 56 percent of ether-insoluble cutin.

New York fruit in 1929 had higher amounts of ursolic acid, oily fraction, and total ether extract at maturity and at the end of storage than did Wenatchee fruit. Individually the same varieties from the two localities varied somewhat with respect to quantities of constituents. Certain varieties, such as Rome Beauty, Baldwin, and Rhode Island Greening, showed only small variations in the value of ether-soluble constituents with regard to origin, while Grimes Golden, Delicious, and McIntosh varied considerably.

Classification of 135 varieties and species of peaches and nectarines on basis of fruit bud set at New Brunswick. M. A. BLAKE (*New Jersey Stat. Circ.* 274 (1933), pp. 4).—Tabulated data, based on records taken over a period of three years, show that sharp differences exist between varieties with respect to bud set. For example, the Greensboro peach developed a bud set of 29, 29, and 31 fruit buds per 12 in. of twig growth in 1930, 1931, and 1932, as compared with 9, 6, and 8 buds, respectively, for Brackett.

New Jersey standard for classifying the set of fruit buds upon peaches. M. A. BLAKE (*New Jersey Stat. Circ.* 271 (1933), pp. 4, fig. 1).—Stating that the general terms, such as heavy set and light set, are confusing, records were taken on unbranched new growths approximately 12 in. in length at the tips of the stronger side branches 5 to 8 ft. above the ground. Twigs with 40-60, 30-39, 20-29, 15-19, 10-14, and below 10 buds were classified, respectively, as exceptional, unusual, extra good, good, fair, and light. *Prunus kansuensis* alone fell in the exceptional class, and Elberta was in the good class. The author concedes that all classes except the light should provide sufficient buds for a full crop of fruit.

Peach harvesting studies. F. M. COE (*Utah Sta. Bul.* 241 (1933), pp. 60, pl. 1, figs. 14).—Based on four seasons' work with Elberta, Early Elberta, and J. H. Hale peaches obtained from trees of different age, vigor, and cultural treatment, the author concludes that while there are considerable variations in pressure test readings and in ground color under different conditions and in different years these were the most useful and accurate indexes to maturity. Fruit from trees of moderate vigor with good exposure to sunlight was generally ready for picking at a pressure range of 12 to 18 lb. and with a ground color of sulfur yellow or sulfur yellow to amber. In the case of fruit from highly vigorous trees with dense tops the optimum pressure range was from 15 to 18 lb. and the ground color greenish yellow and sulfur yellow. A chart

illustrating the colors is included. Fruit from weakly vegetative trees could be picked over a wider range of pressure readings and colors than was possible in the case of vigorous trees, but it was difficult to secure desirable size.

As regards varieties, J. H. Hale because of its greater firmness could be picked in a somewhat more advanced stage of maturity than Elberta or Early Elberta. There was a significant negative correlation between ground color and pressure tests in both the Elbertas. No consistent differences in firmness, pressure tests, or storage quality was apparent between different sized peaches of the same color and firmness before storage.

In all three varieties red coloration increased markedly in quantity as the picking season was deferred. However, the amount of red in fruits of the same ground color was less in the later pickings. Percentage sugar content increased markedly as harvesting was delayed. In 1932 the increase in total sugars ranged from 16 to 25 percent in 5 days. Size also increased until the fruits were soft ripe.

Gooseberries: Varieties, breeding, culture, and use, A. F. YEAGER and E. LATZKE (North Dakota Sta. Bul. 267 (1933), pp. 19, figs. 13).—In crosses between the native wild gooseberry of the Red River country, namely, *Ribes missouriense*, and cultivated varieties, such as Oregon, Houghton, Downing, Red Jacket (Josselyn), and Carrie, those combinations with Oregon as one parent yielded the outstanding results, three of the seedlings, Pixwell, Abundance, and Perry, herein described, being sufficiently valuable for dissemination. Oregon apparently carries a dominant factor for dwarf growth in a heterozygous condition, since two distinct types, dwarf and tall, were obtained from crosses with the wild gooseberry of the Red River Valley.

Supplemental to the breeding results the authors discuss culture, pruning, spraying, and utilization of gooseberries, recipes being presented for jelly, jam, and preserve making.

Raspberry growing in New York State: Cultural practises and disease control, G. L. SLATE and W. H. RANKIN (New York State Sta. Bul. 625 (1933), pp. 62, figs. 10).—Based on experimental work at the station and elsewhere, there is presented a general discussion of factors bearing on the maintenance of vigor and the production of satisfactory crops of good quality fruit. Following a discussion of varieties, pruning, culture, harvesting and marketing, etc., considerable attention is devoted to mosaic diseases, their symptoms, effects on growth and yield, use of resistant varieties, means of preventing rapid spread, etc. Other troubles discussed include anthracnose, streak, leaf curl, rust, spur blight, root gall, powdery mildew, and winter injury.

Citrus orchard management in the Lower Rio Grande Valley, W. H. FRIEND (Texas Sta. Circ. 67 (1933), pp. 1-40, 49-56, figs. 23).—A general discussion is presented of varieties, species, planning, planting, culture, irrigation, spraying, and other items in the general care of orchards. The various types of diseases occurring in the valley are described, with suggestions for control, and information is given on protecting bearing orchards from the wind and freezes. The storage of citrus fruits is briefly discussed and a calendar of orchard management given. A section on insects is noted on p. 384.

The American rose annual, edited by J. H. MCFARLAND and G. A. STEVENS (Harrisburg, Pa.: Amer. Rose Soc., 1933, pp. 184, pls. 25).—General information is presented on rose culture and rose varieties. Among the papers included are the following: Rose-Disease Investigations (pp. 87-101), by B. Parsons and L. M. Massey, and Leaf-Shedding and Wilt of Roses (pp. 102-104), by H. R. Rosen.

FORESTRY

Forest education, H. S. GRAVES and C. H. GUISE (*New Haven: Yale Univ. Press; London: Humphrey Milford, Oxford Univ. Press, 1932, pp. XVII+421, figs. 2*).—The results are presented, with discussion, of a study of forest education conducted under the auspices of the Society of American Foresters and supported by a grant from the Carnegie Corporation.

The importance of the origin of seed used in forestry, H. G. CHAMPION (*Indian Forest Rec., 17 (1933), No. 5, pp. VII+76, pls. 12*).—Assembling information from various sources, the author analyzes progress to date, points out promising fields for investigation and the difficulties to be encountered, and discusses experimental technic that should be followed in attaining results.

The effect of different species of tree on the soil [trans. title], V. T. AALTONEN (*Commun. Inst. Forest. Fenniae, No. 17 (1932), [Art.] 5, pp. 88, figs. 24; Eng. abs., pp. 63-67*).—Chemical and physical studies of soils lying beneath pure larch stands, pure pine, and mixtures of pine and spruce showed only comparatively small differences in composition. In the humus layer of the larch plats ammonia was somewhat more abundant, nitrification capacity somewhat weaker, pH generally lower, and the loss on ignition greater than in the soil of the other plats. The mineral soil of the larch stand contained less lime and often more phosphoric acid than did the corresponding soil of the other stands.

The author concludes that chemical properties of soil show considerable variation, irrespective of the forest type, and that substantial differences would be required to influence the forest type. The major result of the study is said to be its demonstration of the difficulty of determining the effect of a given species on the productivity of a locality through examination of the soil.

Effect of soil reaction on the early growth of certain coniferous seedlings, H. L. SUNDLING, A. C. MCINTYRE, and A. L. PATRICK (*Jour. Amer. Soc. Agron., 24 (1932), No. 5, pp. 341-351*).—Observations at the Pennsylvania Experiment Station on the growth and development of roots and tops of white, jack, and red pines and Norway spruce seedlings planted in three different types of soil held at different pH levels by the use of sulfur or slaked lime showed different responses according to the soil and according to the species. In the Morrison sand the optimum acidity for growth and development was between pH 5 and 6, whereas in Wheeling silt loam in which the pH ran naturally from 6.2 to 6.8 the natural alkalinity was apparently deleterious to the seedlings, and improved growth followed the application of sulfur. In the Hagerstown silty clay loam the best seedling growth was obtained with pH values in the vicinity of 7.

As a whole the results were said to indicate that soil acidity either directly or indirectly is an important factor in the growth and development of conifer seedlings.

Some summer-wood percentage relationships in the southern pines, J. E. LODGEWICK (*Jour. Agr. Res. [U.S.], 46 (1933), No. 6, pp. 543-556, figs. 9*).—Stating that summer wood, because it has a larger proportion of cell wall substance per unit area of volume than has spring wood, imparts density to timber, the results are presented of a study of approximately 10,000 rings of second-growth longleaf and loblolly pines from Florida, North Carolina, and Virginia.

The general relationships between the two portions of any annual ring and the width of the ring itself held as well for second-growth loblolly as for

second-growth longleaf pine. Preliminary observations on pitch pine and scrub pine showed a similar situation, suggesting that the relationship may hold for all second-growth southern pines.

The maximum percentage of summer wood attained at stump height was approximately that attained at breast height in a stand containing 350 trees per acre. However, the maximum percentage of summer wood attained at a given height in the tree appeared to be independent of the density of stocking. The maximum percentage of summer wood at a given height in the bole occurs only in the narrowest rings in crowded stands, but in more open stands this maximum may be maintained in wider rings. On any cross section the relationship between the percentage of summer wood and the ring width might be expressed by a parabola which is concave downward. Conversely, the relationship between spring wood width and ring width in the same material could be expressed by a parabola concave upward. In the outer rings, beyond the eighth, the relation between the summer wood width and ring width could be expressed by a straight line with a positive slope.

Some aspects of an early expression of dominance in white pine (*Pinus strobus* L.), J. L. DEEN (*Yale Univ. School Forestry Bul.* 36 (1933), pp. VII+34, pls. 2).—Studies in 29 plats located in optimum white pine areas of southern New Hampshire and Vermont indicated that white pine possesses an inherent ability to express dominance, and that such dominance is expressed more favorably on good than on poor quality sites. The standard deviation of diameter at breast height was found a satisfactory criterion of an expression of dominance in stands of like age. Because of a lack of competition, dominance was less noticeable in sparsely stocked stands. In closed stands there was observed a weak expression of dominance, accompanied by a comparatively slow growth of the dominant trees. Thinning operations involving the removal of over-vigorous trees with large branchy crowns tended to reduce the expression of dominance and to make the stand more uniform. Thinning operations designed to favor the stronger trees would, on the other hand, increase the expression of dominance.

Studies in Indiana farm woods.—I, The natural regeneration of farm woods following the exclusion of livestock, R. K. DAY and D. DENUYL (*Indiana Sta. Bul.* 368 (1932), pp. 48, figs. 25).—That the rehabilitation of farm woods is one of the major forestry problems in Indiana is indicated by the fact that more than 80 percent of the total timber area of that State is classified as farm woodland. Continuous grazing, as practiced over most of the region, has gradually destroyed the woodlands by preventing reproduction and in many instances by actually damaging the trees. In many cases because of the extreme environmental changes which have taken place through years of overgrazing, farm woodlands have reached the stage where speedy natural recovery is impossible, due to the limiting factors of tight sod and insufficient overhead canopies.

Four stages, namely, early, transition, open park, and final, in the passing of well-timbered areas to open pasture are discussed, with the statement that the regenerative capacity of grazed woodlands appears to be closely correlated with the stage existing at the time livestock are excluded. In areas which have not passed the early stage natural reproduction may bring about satisfactory regeneration of the existing species. However, when the final stage is reached the tight sod persists for many years, preventing a material establishment of tree species. Woodlands at this stage are deemed beyond a condition of satisfactory regeneration of desirable species by natural means.

Protect hardwood stands from grazing, W. K. WILLIAMS (U.S. Dept. Agr. Leaflet 86 (1933), pp. 4, figs. 4).—Stating that the foliage of a number of desirable hardwoods is relished by cattle and that much harm may also arise from their constant trampling of the soil, the author urges the exclusion of livestock from the farm woods if timber production is desired.

DISEASES OF PLANTS

Mycology and plant pathology (5. Internatl. Bot. Cong., Cambridge, 1930, Rpt. Proc., pp. 346-418).—Papers on the effect of environment on disease included The Relation of Environment to Disease in Plants, by L. R. Jones; The Effect of Environment on the Development of Seedling Blight in Wheat and Maize and the Nature of Resistance, by J. G. Dickson; Environment and Non-parasitic Disease, by H. G. Lundegårdh; The Infection of Cotton Plants by *Bacterium malvacearum* in Control Chambers, by R. H. Stoughton; Methods in Systematization of the Basidiomycetes [trans. title], by R. Maire; and Mycological Nomenclature, by J. Ramsbottom. Papers on the significance of heterothallism and hybridism in fungi included The Biological Significance of Conjugate Nuclei in the Basidiomycetes, by A. H. R. Buller; Inheritance of the Albinistic Nonconidial Characters in Interspecific Crosses in the Genus *Neurospora*, by B. O. Dodge; The Significance of Heterothallism and Hybridism in Rust Fungi, by J. H. Craigie; Studies on *Coprinus disseminatus* [trans. title], by R. Vandendries; The Changes Induced in the Cytoplasmic Structure of Cells by Virus Diseases, by J. Dufrenoy; The Biological Relationship between Septobasidium and Scale Insects, by J. N. Couch; Some Observations on Entomogenous Fungi, by T. Petch; and Some Phycomycetes [trans. title], by A. Scherffel. Papers on the differentiation and classification of plant viruses included The Differentiation and Classification of Plant Viruses, by J. H. Smith and by J. C. G. Ledingham; The Challenge of Plant Virus Differentiation and Classification, by J. Johnson and I. Hoggan; On the Differentiation and Transmission of Virus Diseases of the Solanaceae, and the Dependence of Their Occurrence and Spread on the Nutrition of the Plants, by E. Schaffnit; and Methods of Identification and Differentiation of Plant Viruses, by H. M. Quanjer. Papers on the action of sulfur as a fungicide included The Nature of the Fungicidal Action of Sulfur, by B. T. P. Barker; Sulfur as a Fungicide, by W. Goodwin; The Influence of the Season of Felling the Trees on the Resistance of the Timber to Wood-Destroying Fungi, by E. A. Gäumann; Studies on the Morphology and Cytology of the Myxobacteriaceae [trans. title], by S. Krzemieniewski; On the Formation of Conidia in Some Phoma-like Fungi, by H. Klebahn; On the Question of Races in Cereal Rust [trans. title], by O. Appel; *Botrytis cinerea* and the Species Problem, by W. B. Brierley; Experiments on the Physiology and Genetics of the Smut Fungi, by S. Dickinson; Investigations on "Mal Secco" of Lemon in Sicily Due to *Deuterophoma tracheiphila* Petri, by G. Savastano and H. S. Fawcett; and The Cultivation of Fungi, by J. Westerdijk. Papers on the dissemination of cereal rusts included The Dissemination of Cereal Rusts, by E. C. Stakman; The Source and Spread of Stem Rust in Western Canada, by J. H. Craigie; and Annual Outbreaks of Rusts on Wheat and Barley in the Plains of India, by K. C. Mehta.

[Plant disease studies by the Maine Station] (Maine Sta. Bul. 363 (1932), pp. 274-294, 303, 304, figs. 5).—Data are reported on findings as to potato mosaic and other degeneration diseases, by D. Folsom et al., in part in cooperation with the U.S.D.A. Bureau of Plant Industry (pp. 274-278, 304); rots of potato tubers and seed pieces, by Folsom and R. Bonde (pp. 278, 279); potato spraying and dusting for late blight, by Bonde (pp. 280-284); a home-made

colloidal copper spray, by W. P. Raleigh (pp. 284, 285); potato seed treatment to control *Rhizoctonia*, by Raleigh and Bonde (p. 285); control of apple scab (pp. 285-288) and cucumber diseases (pp. 289, 290), both by Folsom; witches' broom and other blueberry diseases, by F. L. Markin (pp. 291-294); and yield losses from late blight of potatoes and a promising blight-resistant potato, both by Bonde (pp. 303, 304).

[Plant disease studies by the New Hampshire Station] (*New Hampshire Sta. Bul.* 270 (1933), pp. 12, 13).—Findings are reported as to potato mosaic and leaf roll, the control of apple scab, the preservation of Burgundy mixture with tartaric and citric acids, and the toxicity of sodium bicarbonate and sodium sulfate in Burgundy mixture.

[Disease control] (*New Jersey Stat. Circs.* 278-280, 282-284 (1933), pp. 2 each).—Entitled, respectively, Blossom-End Rot of Tomatoes, Cedar Rust of Apples, Corn Smut, Orange Rust of Blackberry and Raspberry, Cabbage Yellows, and Bacterial Wilt of Sweet Corn, these circulars discuss briefly the nature, cause, and control of the several troubles.

The fungi of India, E. J. BUTLER and G. R. BISBY (*Imp. Council Agr. Res. [India], Sci. Monog.* 1 (1931), pp. XVIII+537, pl. 1).—In the introductory part the authors deal with the history of the fungi in India, their distribution, characters of the fungus flora, etc. A list of the species of fungi of India arranged in systematic order, with notes on many, is then presented, followed by a list of synonyms and other names found to have been applied to Indian fungi (pp. 167-173), a bibliography of 526 titles (pp. 174-209), and a host index (pp. 210-237).

[Reports of the mycologist, Burma, Mandalay, for the years ended March 31, 1930 and 1931] ([*Burma Dept. Agr.*] *Rpt. Mycol.*, 1929-30, pp. 8; 1930-31, pp. 8).—Among the newer diseases observed by D. Rhind during the year ended March 31, 1930, are die-back of coffee, *Pestalotzia palmarum* of coconut, canker and gummosis on sour lime, *Helminthosporium turcicum* and *Phyllachora sorghi* on sorghum, and *Oidium* sp. on sesame, impatiens, and zinnia. The 1931 account, by M. T. Su, deals in some detail with the activity on *Cicer arietinum* of *Rhizoctonia bataticola*; on *Phaseolus lunatus* of *Macrophomina phaseoli* (*R. bataticola*?); on dead cotton of *R. bataticola*; on *Piper betle* of *Phytophthora colocasiae*; on chillies of *Gloeosporium piperatum*; on *Allium ascalonicum* of *Alternaria* sp.; on *Aleurites fordii* of *Corticium* sp.; and on *Broussonetia papyrifera* of *Fomes lamacensis* and *F. lignosus* (?).

[Annual reports of the mycologist for the years 1928-29 and 1929-30], K. R. MOHENDRA (*Punjab Dept. Agr. Rpts.* 1928-29, pt. 2, I, pp. 79-94; 1929-30, pt. 2, I, pp. 24, pls. 8).—In the first of these reports since the establishment of the position of mycologist beginning August 28, 1928, an account is given of conditions then existing and of subsequent changes and operations, with discussion of diseases of economic plants, and lists of diseases newly recorded in the Punjab plains during the year. The second report contains a corresponding list of diseases newly recorded.

Bacteriophage and its possible relations to the control of plant parasites, B. B. MUNDKUR (*Jour. Indian Bot. Soc.*, 9 (1930), No. 4, pp. 211-217).—A brief inquiry is outlined as to the nature of bacteriophage, its properties, its origin, its relations to bacteria in plants (legume and plant pathogenic bacteria), and the presence of such a lytic principle in connection with the fungi.

The inhibitory action of certain substances on the growth of mould fungi, R. G. FARGHER, L. D. GALLOWAY, and M. E. PROBERT (*Brit. Cotton Indus. Res. Assoc., Shirley Inst. Mem.*, 9 (1930), pp. IV, 37-52).—An outline is given

of the properties required of an antiseptic suitable for general protective use in the cotton industry, with discussion of the results of investigations carried out as to the influences of various substances on the growth of mold fungi on nutrient media in the laboratory. A tabular showing is made as to the results of biological tests on about 160 antiseptics, including inorganic, organomercury, and organic compounds. Several substances were found to possess outstanding toxicity toward mold fungi, prominent among which are salicylanilide, *o*-chloromercuriphenol, *p*-acetoxymercuriacetanilide, thallium carbonate, *p*-nitrophenol, and trichlorophenol. "Of these only salicylanilide ('Shirlan') appears to combine a sufficient number of the desirable properties of an antiseptic for general use in the cotton industry. Solutions of this substance appear to be non-toxic to plant life." The preparation is briefly indicated of substances, uncommon or previously unknown, which have been used in these tests.

The carbon metabolism of *Fusarium oxysporum* on glucose, A. K. ANDERSON, E. L. EVERITT, and P. D. ADAMS (*Jour. Agr. Res. [U.S.]*, 46 (1933), No. 5, pp. 473-482, fig. 1).—The main metabolism products of *F. oxysporum* on glucose determined in Pennsylvania Experiment Station studies were carbon dioxide and ethyl alcohol, found in such proportions as to indicate that the organism causes a rather typical alcohol fermentation, resembling *F. lini* (E.S.R., 57, p. 348) in this respect, although *F. oxysporum* made little or no use of ethyl alcohol as a food while *F. lini* very definitely used it.

Experiments with potato cuttings in ethyl alcohol solutions suggested that this product is not responsible for the wilting of potato plants. Cuttings placed in solutions of various strengths became chlorotic and gave off a cantaloup odor. In solutions containing 5 percent and less of alcohol no wilting occurred, whereas there was definite and rapid wilting in 10 percent and stronger alcoholic solutions.

Ophiobolus graminis and O. herpotrichus and the diseases they cause in Triticum vulgare and other cereals, J. H. J. VAN DE LAAR (*Onderzoekingen over Ophiobolus graminis* Sacc. en *Ophiobolus herpotrichus* (Fr.) Sacc. en over de door Deze Fungi Veroorzakete Ziekten van Triticum vulgare Vill. en Andere Gramineae. Proefschr., Landb. Hooges., Wageningen, 1931, pp. [8] + 146 + [5], pls. 12, figs. 2).—This is a Wageningen doctor's thesis.

Cotton diseases [trans. title], A. A. TACHEVSKIĬ (*Trudy Prikl. Bot., Genet. i Selk. (Bul. Appl. Bot., Genet. and Plant-Breeding)*, 24 (1930), No. 5, pp. 294, figs. 25).—In this extensive monograph cotton diseases are dealt with under the chapter headings of historical data (pp. 3-30) and diseases of cotton in various regions (pp. 30-266). Data are presented on such topics as the physiology of the causative organisms, descriptions of varieties, and disease control. References given include about 198 from foreign literature and 20 from the Russian.

The fungi causing mildew in cotton goods, L. D. GALLOWAY (*Brit. Cotton Indus. Res. Assoc., Shirley Inst. Mem.*, 9 (1930), pp. III, 27-36, pl. 1, fig. 1).—An account with summations is given regarding the occurrence and characters of the fungi isolated in pure culture during routine examination of mildew cases, and regarding the difficulties as to classification of forms. Discussion is given on the extent and effects of infection, control methods, and distribution.

Most of the species (about 180) listed belong to the genera *Aspergillus* and *Penicillium*, but species pertaining to *Fusarium* and other forms are frequent. Raw cotton is the principal source of infection. Of the fungi, a comparatively small proportion can cause stains on cloth, and a smaller still can cause tendering of the fabric under the ordinary conditions of exposure.

Control of Alternaria blight of glasseng with Bordeaux mixture and injuries accompanying its use, H. A. RENNELS and J. D. WILSON (*Ohio Sta. Bul.*

522 (1933), pp. 16, figs. 4).—This disease, occurring in commercial gardens and believed to have been present also on plants in their native habitat, rarely kills ginseng but dwarfs the plants seriously and thereby reduces yields. Over a period of 5 years various materials, such as Bordeaux mixture, colloidal copper, colloidal sulfur, and monohydrated copper-hydrated lime dust, were tested for the control of *Alternaria* blight, with the observation that none of the sprays containing copper or sulfur were effective, with the exception of Bordeaux mixture and Pyrox. Bordeaux mixture 3-4.5-50 used alone gave very satisfactory control in 3 of 4 years in which tested. The addition of soap made the spray easier to apply but had no material benefit in control. Since the addition of calcium arsenate increased the effectiveness of Bordeaux mixture, it is suggested that 1 lb. of potash fish-oil soap and 1 lb. of calcium arsenate be added to each 50 gal. of the Bordeaux spray.

Bordeaux mixture was found capable of causing injury to ginseng if improperly made, if applied during freezing weather, and if applied during periods of drought. The critical soil moisture range with relation to Bordeaux mixture leaf injury was in the summer of 1931 between 12 and 17.5 percent, computed on the basis of the dry weight of the soil; hence if irrigation is unavailable it is recommended that spraying be postponed until sufficient rains have fallen to wet the soil thoroughly.

The downy mildew of the hop in 1929, E. S. SALMON and W. M. WARE (*Jour. Inst. Brewing*, 36 (1930), No. 2, pp. 63-67).—Listing accounts regarding hop downy mildew (*Pseudoperonospora humuli*) since its alleged first appearance (1924) in England, some of which have been noted (E.S.R., 68, p. 55), the authors indicate the main features of the hop downy mildew attack on the bines of 1929, said to be almost as severe as that of 1928. The facts cited tend to show that the majority of spikes either arise from infected buds or they become infected by zoospores as they are developed in the early spring. In the south of England downy mildew remained quiescent during the hot, dry summer, though it was clear that sufficient infection existed to enable the disease to become dominant, perhaps to the extent of destroying the cones if wet weather had occurred. The varieties affected included Early Bird, Bramling, Goldings, Stumps, and Tolhurst. Fuggles was indicated by one grower as quite free from attack.

"The experience of the last five years shows clearly that considerable risk is taken if hop gardens are not sprayed to protect the foliage from infection, since it is on this that spores are formed during the summer months." An improved sprayer is described as securing a very efficient wetting of the "heads", with good results. Homemade Bordeaux mixture at 1 percent has proved to be easily made on the farm and entirely safe for use on hops until the cones approach ripeness, when the need arises for another fungicide for the nearly-ripe cones. The discovery that the zoospores are killed in solutions containing over 0.1 percent of soft soap may prove to be of practical value.

Substances toxic to the downy mildew of the hop, W. NEWTON and C. YARWOOD (*Jour. Inst. Brewing*, 36 (1930), No. 2, pp. 67, 68).—Sap bleeding from cut tips of hop plants was found to be toxic to zoospores of the downy mildew organism, *Pseudoperonospora humuli*, but sap from the cut bases of the stems was practically nontoxic, as was also that expressed from ground-up material of hop and other plants. Commercial pine resin dissolved in methyl alcohol and potassium hydroxide was more toxic to the zoospores than was copper sulfate.

Rhabditis lambdicensis, a nematode possibly acting as a disease agent in mushroom beds, G. STEINER (*Jour. Agr. Res. [U.S.]*, 46 (1933), No. 5, pp. 427-435, figs. 4).—A detailed description is presented of a nematode believed to be a probable carrier and distributor of a pathogenic agent (*Bacterium tolaasi*)

causing a black-spot or brown-spot disease of mushrooms. Since nematodes travel readily on moist surfaces and since mushroom beds must be sprinkled regularly, the author concedes that an ideal opportunity is provided for the nematodes to spread rapidly, carrying with it either externally or internally the pathogenic bacterium.

Abnormal enlargement of peas from plants affected with root-rot, J. G. HORSFALL and Z. I. KERTESZ (*New York State Sta. Bul. 621 (1933), pp. 20, figs. 6*).—Observations in 1931 and 1932 upon the comparative size of peas harvested from healthy and from diseased plants showed that as long as a plentiful supply of water was present in the soil diseased peas grew larger and remained larger than did peas on healthy vines, even if they were of equal age, as determined by the number of days from blossoming. However, when the soil moisture fell below a point where the diseased roots could absorb water easily the peas on the diseased vines shriveled and became smaller than those on healthy plants. If shriveling had not progressed too far subsequent rains caused some reenlargement of the peas.

The authors believe that the abnormal enlargement of peas on diseased vines may be correlated with a more rapid growth of the seeds at the expense of the vines. That earlier blooming was not a factor was shown in observations on tagged blooms. Blooming rates were somewhat slower for plants affected with root rot, although the growth rate was undoubtedly faster.

Peas, both healthy and diseased, derived in 1932 from late blooms grew more slowly but attained a larger size than did the comparable product of early blooms. Here again, however, peas on diseased plants grew the more rapidly. The authors suggest that root rot may offer a partial explanation of why it is sometimes difficult to obtain good quality, large size peas.

The control of apple diseases in Quebec in relation to cultural methods, H. N. RACICOT (*Quebec Soc. Protect. Plants Ann. Rpt., 22 (1929-30), pp. 49, 50*).—In Quebec the apple-growing districts are not far from the northern limits of growing apples for profit. There are fewer parasitic diseases and more disorders due to climatic and related conditions followed by secondarily or weakly parasitic diseases. Winterkilling or injury results from imperfect maturing of newly formed wood, also from use of fertilizers prolonging growth, a result which also follows too close pruning. Winter injury with resultant weakening is followed by such diseases as black rot canker, silver-leaf, and collar rot. Appropriate treatment and orchard practices are outlined.

Further studies of the brown rot fungi.—IV, *Sclerotinia fructigena* as the cause of an apple canker, H. WORMALD (*Brit. Mycol. Soc. Trans., 15 (1930), pt. 1-2, pp. 102-107, pl. 1*).—In continuation of accounts previously noted (*E.S.R., 65, p. 540*), a description is given of a severe infection of Melon apple trees due to *S. fructigena*. The infection extended back from the fruit via the spurs to the branches, causing branch cankers, which girdled the branches and killed the parts beyond. Monilia pustules appeared in August, ceasing to function on the approach of winter but showing new pustules the following June. Brief reference is made to similar infection on four other apple varieties.

The fire blight problem, J. E. MACHACEK (*Quebec Soc. Protect. Plants Ann. Rpt., 22 (1929-30), pp. 56-67*).—Fire blight, recently serious on pomaceous and especially on stone fruits, particularly in southern Quebec, is said to be native in North America, attacking cultivated and wild hosts, including pear, apple, quince, wild and cultivated crab apples, service berry, hawthorn, California holly, mountain-ash, apricot, yakimine, cheney plums, prunes, cherries, loquat, strawberries, and in one supposed case Lombardy poplar. It was causing loss in Japan in 1911, was epidemic in New Zealand in 1919, and was present in

Italy in 1925. An account is given as to the symptoms, pathologic anatomy, host relationships and varietal susceptibility, mode of infection, and control, including formulas for a mercury-glycerin disinfectant and for a Bordeaux (dust) oil paint.

Observations on the ascospore discharge of *Venturia inaequalis* in relation to certain environmental factors, G. C. CHAMBERLAIN (*Quebec Soc. Protect. Plants Ann. Rpt.*, 22 (1929-30), pp. 68-78, figs. 5).—During seven years of spray experiments to control apple scab observations were made as to periods of ascospore discharge, and these are here recorded along with temperature and precipitation records as there appears to be a striking correlation over a period of years between these two environmental factors and ascospore discharge. The data were secured from overwintered leaves of the McIntosh variety showing abundant production of perithecia. A tabular exposition is presented. Ascospore discharge shows no direct correlation with host development, and the records here presented are held to indicate the advisability of basing spray schedules on ascospore discharge and precipitation data and not on host development alone.

Control of apple scab in the Quebec region, O. CARON (*Quebec Soc. Protect. Plants Ann. Rpt.*, 22 (1929-30), pp. 47, 48).—The result of organized attempts at apple scab control in the parishes of St. Nicholas and St. Etienne was that whereas the estimate of the quality of the apple harvest gave for 1928 of choice apples 5 percent, salable 50 percent, and culls 45 percent, that of 1929 gave figures of 60, 25, and 15 percent, respectively, though an important spray was omitted in the latter year.

Evaluation of applications of lime-sulfur for the control of apple scab, W. O. GLOYER (*New York State Sta. Bul.* 624 (1933), pp. 39, figs. 7).—Working with Ben Davis trees planted on the station grounds in 1916, it was found in studies extending over a 3-year period that lime-sulfur spray was most effective in the control of scab when the time of application coincided with the vulnerable stages of the scab organism. However, a single application that occupied a strategic position in the spray program in one year might prove of little value another season. Apparently lime-sulfur spray may be eradivative as well as protective. In the three years the single delayed dormant, the preblossom, the calyx, and the first cover spray exerted eradivative functions. For example, the single delayed dormant spray of 1932, applied prior to the first rain period so as to inhibit primary infection, showed only 15 percent scabby fruits at harvest as compared with 50 per cent for a single protective application.

The so-called Geneva or double stairlike system of application, providing an increasing and a decreasing series, was used in the study so that single, deferred, and various sequences of sprays could be compared. Lime-sulfur used as a summer spray injured both fruit and foliage in two of the three years. Leaf counts in July sometimes showed trees with heavy foliage infection but with no scabby fruits.

In concluding, the author points out that modifications of spray programs on the basis of scab development can be made only after similar testing of other varieties and in various fruit-growing districts.

Cranberry false blossom, C. S. BECKWITH (*New Jersey Stat. Circ.* 275 (1933), pp. 4, figs. 4).—Transmitted from vine to vine by the blunt-nosed leafhopper, the control of cranberry false blossom disease is said to lie primarily in the elimination of the insect by spraying with pyrethrum solutions or by flooding the bogs with water. However, it is pointed out that neither of these measures will eradicate the disease but simply serve to stop its spread, and incidentally to increase the crop considerably.

False blossom inoculation experiments at Toms River, New Jersey, 1928 and 1929, R. B. WILCOX (*Amer. Cranberry Growers' Assoc. Proc. Ann. Meeting*, 60 (1930), pp. 11-16).—"This experiment showed impressively the ease with which false blossom infection can be secured."

Raspberry diseases and their control in Quebec, H. N. RACICOT (*Quebec Soc. Protect. Plants Ann. Rpt.*, 22 (1929-30), pp. 51-54).—Raspberry diseases of present economic importance in Quebec, including mosaic, leaf curl, spur blight, and anthracnose, are dealt with from the standpoint of ready recognition and economical control.

The Phytophthora disease of the calla in America, K. S. CHESTER (*Jour. Arnold Arboretum*, 11 (1930), No. 3, pp. 169-171).—In 1930, the author studied a diseased condition of the calla lily (*Zantedeschia (Richardia) aethiopica*) in a greenhouse in Murthas Vineyard, Mass. The plants were imperfect in various ways described, and examination indicated the effects of attack by a *Phytophthora* supposedly identical with the European disease caused by *P. richardiae*. The calla lily disease is said to have been first observed by Buisman in the few years just prior to 1927 (*E.S.R.*, 61, p. 46; 64, p. 152). The formalin treatment essentially as approved by her and as herein outlined was found satisfactory.

Graft-blight of lilac, K. S. CHESTER (*Jour. Arnold Arboretum*, 11 (1930), No. 4, pp. 232, 233).—A disease of lilac (*Syringa vulgaris*), studied by the author since 1928 and named by him graft blight, was observed in nurseries in New England, New York, and New Jersey, also in private plantings, and has also been reported in Oregon, Ontario, and Germany. The plants affected exhibit symptoms of general nutritional deficiency, which are described. Few plants recover.

Although supposedly abiotic as to character and causation, the disease showed no consistent relation to external environment. It was limited, however, to lilacs grafted or budded onto privet stocks, varying with the privet species used, none of which appeared satisfactory. Incompatibility is supposed to exist between lilac scions and privet stocks, and it is supposed that stocks from other members of the Oleaceae are objectionable for the grafting of *S. vulgaris*.

Graft-blight: A disease of lilac related to the employment of certain understocks in propagation, K. S. CHESTER (*Jour. Arnold Arboretum*, 12 (1931), No. 2, pp. 79-146, pls. 4, figs. 7).—This extended paper describes more particularly the disease above noted. "The use of privet (*Ligustrum* sp.) as a grafting understock is demonstrated to be the cause of the symptoms indicated". The symptoms correlating precisely with the use of certain privet species in propagation.

The chief undesirable factor is considered to be a discrepancy in the growth vigor of the two graft symbionts which is caused or aided by the interruption of the elaborated substances in their passage from crown to root system, though other physiological factors are supposedly involved.

Recommendations made include abolishment of the use of lilac as understock, the abolishment or modification of the use of privet in this capacity, and the furtherance of use of own-root methods.

Life-history studies of the species of Phomopsis occurring on conifers, Part I, G. G. HAHN (*Brit. Mycol. Soc. Trans.*, 15 (1930), pt. 1-2, pp. 32-93, pls. 3, figs. 29).—As the result of an investigation of the known species of *Phomopsis* on conifers undertaken to differentiate *P. pseudotsugae*, the cause of the so-called *Phomopsis* disease of Douglas fir, from closely allied forms occurring on this and other conifer hosts, the present status of *Phomopsis*, now regarded as the imperfect stage of *Diaporthe*, is discussed. On the basis of a broad conception of the genus, certain atypical forms whose perfect stages are still

unknown are included in the *Phomopsis* group. These forms approach the form genus *Fusioocum*, although they show a greater affiliation with *Phomopsis*. The eight species differentiated include *P. occulta* (*D. conorum*), *P. juniperovora*, *P. conorum*, *P. montanensis* n.sp., *P. strobil*, *P. pseudotsugae*, *P. abietina*, and *P. boycei* n.sp. The conifer *Phomopsis* spp. exhibited great constancy as regards culture growth characters, of which those shown on a single medium are described for the group.

The conifer *Phomopsis* spp. showed both wide and extremely limited host relationships, as discussed.

Three species of Botryodiplodia (Sacc.) on elm trees in the United States. C. BUISMAN (*Jour. Arnold Arboretum*, 12 (1931), No. 4, pp. 289-296, pls. 2, fig. 1).—In studies of European elm disease, the author isolated fungi from cankers on elm trees showing die-back: *B. malorum* and *B. ulmicola* in case of *Ulmus americana* and *B. hypodermia* in that of *U. foliacea suberosa*. These when studied in natural cankers and in monosporic cultures produced two types of spores, one-celled and two-celled. *B. ulmicola*, said to have been hitherto included under *B. hypodermia*, has been separated as a distinct species.

Elm saplings were inoculated in the greenhouse with spores from each of the three species of *Botryodiplodia*, the spores germinating and an infection resulting in each case. The mycelia of *B. malorum* and *B. ulmicola* persisted in a living condition but caused no cankers, the mycelium of *B. hypodermia* invading adjacent tissues and causing typical cankers.

Brown bast: Some considerations as to its nature, E. RHODES (*Rubber Res. Inst. Malaya, Quart. Jour.*, 2 (1930), No. 1, pp. 1-11, pls. 4).—Brown bast disease is said to be best considered as a phenomenon closely related to the tree reaction of wound healing and obeying the same general laws. A pathological condition, occasionally occurring in a few vessels after tapping, is followed by the deposition of wound gum and the formation of burs. The wound-gum deposition is said to be essentially a process carried out by enzymes normal to the tree and closely linked with its state of vigor.

This linking of the disease with enzyme activity and tree vigor enables a simple explanation of several obscure but fundamental points connected with its incidence. A new light is also thrown upon the relation between brown bast trees and so-called dry trees in small holdings.

Some observations of the mildew leaf disease of Hevea brasiliensis due to Oidium hevea. A. R. SANDERSON (*Rubber Res. Inst. Malaya, Quart. Jour.*, 2 (1930), No. 1, pp. 16-30).—It is said to have been definitely established that *Oidium* leaf disease is present throughout the rubber-growing areas of the eastern Tropics (except south India and Burma), and that it overwinters there and tends to increase year by year. The repeated defoliations occurring each season are thought to affect adversely both the yield and the vigor of the tree.

Original infection and rapid local spread are favored by dry-weather conditions during the winter period. Control is easily secured through the use of sulfur spray or dust, though repeated applications are needed in the winter season at short intervals. The attack occurs at all ages, including the nursery period, and is supposedly due to wind dispersal of the spores (conidia), which are produced more abundantly during the dry weather characterizing a normal winter season when the leaves are presumably most susceptible.

Pecan rosette: Soil, chemical, and physiological studies, A. H. FINCH and A. F. KINNISON (*Arizona Sta. Tech. Bul.* 47 (1933), pp. 407-442, figs. 12).—Stating that rosette has caused the abandonment of pecan orchards in certain valleys of Arizona, the authors present the results of studies upon the nature

and control of this trouble. Studies of the soluble salt content of soil samples collected by horizons showed no clear relationship between salts and the occurrence of rosette, although the trouble was common on soils containing a high salt content. Severe rosette occurred where the black alkali content ranged from 0 to more than 204 p.p.m., but in the areas studied healthy trees were never found on soils containing more than 12 p.p.m.

Of various chemicals, including compounds of iron, magnesium, manganese, zinc, potassium, phosphorus, and sulfur inserted in a dry condition or in solution in the trunks, the zinc salts were outstanding in their beneficial effects. In severely rosetted trees following introduction of zinc into the trunk, dying back of the shoots was arrested, and in from 3 to 6 days the new unfolding leaves of lateral buds became definitely greener. Dipping or spraying of young diseased leaves with solutions of zinc was followed by improvement, suggesting perhaps that the zinc applications could be made as part of the spray program. Analyses of diseased leaves and shoots showed them to contain less zinc than did healthy material. The roots of diseased trees apparently were unaffected. Irrigation waters of certain districts where rosette was not common contained zinc, whereas in districts where rosette was prevalent the irrigation waters contained no zinc.

Investigations on the spike-disease of sandal, I-V, edited by V. SUBRAHMANYAN (*Bangalore: Indian Inst. Sci., 1931, pts. 1-2, pp. 16; 3, pp. [2]+20; 1932, pts. 4, pp. [2]+16; 5, pp. [2]+18, figs. 2*).—Part 1 includes a condensed statement of the more important observations recorded before April 1, 1931, in connection with the spike disease of sandal. Parts 2 to 5 give reports of the progress made during the quarter ended, respectively, June 30, September 30, and December 31, 1931; and March 31, 1932.

The spread and the control of Phacidium blight in spruce plantations, J. H. FAULL (*Jour. Arnold Arboretum, 11 (1930), No. 3, pp. 136-147*).—Though the spread on spruce in the nursery of blight due to *P. infestans* is rapid if not checked, the fungus was fully controlled in seed beds and in transplant lines by spraying with lime-sulfur late in the fall, and it is believed that this is also practicable in plantations. The blight supposedly spreads from infected to healthy masses of foliage, and neither age nor orientation functions, apparently, in connection with this extension of the disease so long as the air temperature in the snow pockets is sufficiently high. The spread is said to occur largely under the snow melting in the spring. The data are given in tabular form.

The effect of concentration on the toxicity of chemicals to living organisms, E. BATEMAN (*U.S. Dept. Agr., Tech. Bul. 346 (1933), pp. 54, figs. 31*).—Using a strain of the wood-destroying fungus *Fomes annosus*, highly resistant to the toxic action of chemicals and normally producing an easily measured growth in cultures, the author found that under like conditions radial growth of the fungus is directly proportional to the time of growth. There was noted a definite relationship between the concentration and the percentage retardation of fungus growth on nutrient agar containing various chemicals. It was possible to designate this relationship by the general equation $R=DO^n$, in which R is the percentage retardation, O the concentration, n a constant or exponent which seems to be a function of the chemical structure, and D a constant which apparently depends on the individual compound. The exponent n has one value if the poison is an inorganic salt with a poisonous basic radical, another value if an ortho substituted benzene derivative, and still another value if a para or meta substituted benzene derivative. The concept that toxic action may be expressed as a parabolic function of the concentration appeared applicable, within limits, to other organisms, such as aphids, bacteria, and green plants.

ECONOMIC ZOOLOGY—ENTOMOLOGY

Economic mammalogy, J. HENDERSON and E. L. CRAIG (*Springfield, Ill.: Charles C. Thomas, 1932, pp. X+397*).—The first part of this work (pp. 1-184) is devoted to a general discussion presented in 28 sections. The systematic account presented in part 2 (pp. 185-347) is followed by a bibliography (pp. 348-373) and a general index (pp. 375-397).

In days ago: Notes on the fauna and flora of subtropical Florida in the days when most of its area was a primeval wilderness, W. S. BLATCHLEY (*Indianapolis, Ind.: Nature Pub. Co., 1932, pp. 338, pls. 15*).—This further volume (E.S.R., 68, p. 63) on the plant and animal life of Florida reports observations made during the course of six trips between 1911 and 1922 into extreme southern Florida. The occurrence, habits, and value of animals, including birds, mammals, reptiles, batrachians, arthropods, etc., and particularly coleopterous and heteropterous insects are recorded, with generic and in most cases their specific names.

Foods of some predatory fur-bearing animals in Michigan, N. DEARBORN (*Mich. Univ., School Forestry and Conserv. Bul. 1 (1932), pp. 52, pls. 4, figs. 32*).—This account summarizes the findings of a 2-year investigation of the food habits of the principal predatory fur-bearing animals in Michigan, including the opossum, raccoon, red fox, coyote, wild cat, mink, New York weasel, skunk, and badger.

Hints on mountain-lion trapping, S. P. YOUNG (*U.S. Dept. Agr. Leaflet 94 (1933), pp. 8, figs. 5*).—This leaflet, based on the experience of predatory-animal hunters of the Bureau of Biological Survey, has been prepared with a view to aiding stockmen and game protectors in local control of mountain lions.

The rodents of France and the combat of injurious forms [trans. title], A. CHAPPELLIER (*Arch. Hist. Nat. Soc. Natl. Acclim. France, 9 (1932) pp. 139, pls. 6, figs. 49*).—Following a brief introductory part the rodents of France are dealt with in systematic order (pp. 19-80). Control measures for rodent pests are then considered (pp. 81-119), followed by a review of legislative and regulatory control measures (pp. 120-138).

The bird: Anatomy, physiology, appearance, and adaptation, I. F. GROEBBELS (*Der Vogel: Bau, Funktion, Lebenserscheinung, Einpassung. Berlin: Borntraeger Bros., 1932, vol. 1, pp. XII+918, pls. 2, figs. 234*).—This first volume is devoted to (1) the respiratory system, with a 15-page classified list of references (pp. 13-256), and (2) the alimentary system, with a 49-page classified list of references (pp. 257-895). Indexes are included (pp. 896-918).

The birds of Newfoundland Labrador, O. L. AUSTIN, JR. (*Mem. Nuttall Ornithol. Club, No. 7 (1932), pp. [2]+229, pl. 1, figs. 2*).—Following the introductory part, which deals largely with ornithological explorations in Newfoundland Labrador (pp. 1-12), the origin and history of the Labrador avifauna is dealt with (pp. 13-22). Then follows an annotated list of the birds of Newfoundland Labrador (pp. 23-201), a bibliography (pp. 203-219), and a subject index (pp. 221-229).

Abundance and conservation of the bob-white in Ohio, S. C. KENDEIGH (*Ohio Jour. Sci., 33 (1933), No. 1, pp. 1-18, figs. 2*).—The author concludes that the population of bobwhites in Ohio is not of sufficient size to permit of a general open hunting season throughout the State.

Woodpeckers, friends of our forests, T. G. PEARSON (*Natl. Geogr. Mag., 63 (1933), No. 4, pp. 453-479, pls. 8, figs. 10*).—This is the fourth of a comprehensive series of paintings and descriptions of the important families of birds of North America (E.S.R., 68, p. 777).

The meaning of bird control, W. L. MCATEE (*Wilson Bul.*, 45 (1933), No. 1, pp. 3-9).—A discussion contributed from the U.S.D.A. Bureau of Biological Survey.

Forest plantations injured by roosting birds, G. R. STEWART (*Jour. Forestry*, 31 (1933), No. 4, pp. 421-423, fig. 1).—The author reports upon black-birds, starlings, and other gregarious birds roosting in large numbers in pine plantations as the cause of defoliation and death of the immediate trees. Examination of the soil indicates only one essential alteration—the droppings raised the nitrate nitrogen under the dying trees to excessive and toxic proportions.

Notes on the poisonous secretions of twelve species of toads, K. K. and A. L. CHEN (*Jour. Pharmacol. and Expt. Ther.*, 47 (1933), No. 3, pp. 231-293, fig. 1).—This account of 12 species of *Bufo* is presented in connection with a list of 22 references to the literature.

The effects of dehydration upon the hatchability of *Limax flavus* eggs, E. B. CARMICHAEL and T. D. RIVERS (*Ecology*, 13 (1932), No. 4, pp. 375-380).—It was found that fully developed embryos of the slug *L. flavus* L. could suffer a loss of from 35 to 40 percent of their weight and still survive.

The influence of helminth parasitism on the abundance of the snowshoe rabbit in western Canada, R. V. BOUGHTON (*Canad. Jour. Res.*, 7 (1932), No. 5, pp. 524-547, pl. 1, figs. 12).—The author reports upon the results of "a survey of the helminth parasites of 420 rabbits (*Lepus americanus*) from the Province of Manitoba. The survey yielded three species of Cestoda, two larval and one adult form, five species of Nematoda, two of which are regarded as new to science, an unidentified acanthocephalan, and several species of the protozoan genus *Eimeria*. No Trematoda were found. The biology and pathogenicity of the helminth parasites suggest that the three most dangerous parasites to the health of the rabbit population are *Nematodirus triangularis*, *Synthetocaulus leporis*, and *Eimeria* sp. A definite correlation between the percentage of rabbits infested by parasites and the meteorological conditions in the different soil areas of the Province appears to exist."

Faunae of nests of the magpie and crow in western Montana, W. L. JELLISON and C. B. PHILIP (*Canad. Ent.*, 65 (1933), No. 2, pp. 26-31).—Extremely heavy infestations of *Protocalliphora avium* Shan. and Dobr. are recorded from nests of magpies, 373 larvae having been taken from one nest containing 4 fledglings. Forty-seven larvae were found in the nest of a crow. Two hymenopterous parasites, *Marmonia vitripennis* (Walk.) and *Morodora armata* (see page 398), were reared from puparia collected. A total of 16 species of insects and arachnids are recorded from crow and magpie nests in western Montana.

The Zooecidia of plants in South and Central America, C. HOUEAU (*Les Zooecidies des Plantes de l'Amérique du Sud et de l'Amérique Centrale*. Paris: Libr. Sci. Hermann & Co., 1933, pp. 519, figs. 1028).—This, the sixth of a series of publications dealing with the animal galls of plants, three of which relating to the insect and other animal galls of plants in the Mediterranean Basin of Europe have been noted (E.S.R., 30, p. 852), is the first to deal with the American forms. The work includes descriptions and illustrations of the galls, references to their original description, their geographic distribution, a bibliography of 38 pages, and zoological and botanical indexes.

Insect behaviour, E. CHESMAN (*London: Philip Allan*, 1932, pp. VII+139, figs. 6).—A popular presentation of the subject.

The effect of climatic conditions upon populations of insects, P. A. BURTON (*Roy. Soc. Trop. Med. and Hyg. Trans.*, 26 (1933), No. 4, pp. 325-356, figs. 5).—This contribution is accompanied by a list of 63 references to the literature.

The influence of temperature on the life-history of insects, E. JANISCH (*Ent. Soc. London, Trans.*, 80 (1932), pt. 2, pp. 137-168, figs. 9).—This contribution deals with the subject under the headings of length of development and temperature, the course of development, mortality, range of variation, and general conclusions, presented in connection with a list of 15 references to the literature.

The evolution of the respiratory function of the blood, A. C. REDFIELD (*Quart. Rev. Biol.*, 8 (1933), No. 1, pp. 31-57, figs. 6).—This subject is presented in connection with a list of 87 references to the literature.

The progression factor in insect growth, F. S. BODENHEIMER (*Quart. Rev. Biol.*, 8 (1933), No. 1, pp. 92-95).—"Insect growth follows a progression factor of 2 or n^2 for weight, and of $\sqrt[3]{2} = 1.26$ or $n 1.26$ for length. The increase of latent divisions in the Holometabola obscures these relations, without invalidating them."

The migrations of insects [trans. title], G. FRAENKEL (In *Ergebnisse der Biologie*. Berlin: Julius Springer, 1932, vol. 9, pp. 1-238, figs. 36).—This account is presented in connection with a 26-page classified list of references to the literature.

Insect coloration and the relative acceptability of insects to birds, F. M. JONES (*Ent. Soc. London, Trans.*, 80 (1932), pt. 2, pp. 345-386, pls. 11).—This is a report of a series of experiments conducted on the island of Marthas Vineyard, Mass., during the summers of 1930 and 1931. The details are presented in tabular form, and one of the several plates, which is in colors, illustrates the insects refused or accepted by ants.

Fighting the insects: The story of an entomologist, L. O. HOWARD (*New York: Macmillan Co.*, 1933, pp. XVII+333).—This account furnishes much historical information in the field of economic entomology, which supplements the earlier contributions (E.S.R., 64, pp. 601, 648; 66, p. 447).

Insecticides of plant source, I [trans. title], I. HOUBEN (*Anz. Schädlingssk.*, 8 (1932), No. 7, pp. 83-88).—This first contribution, from the chemical laboratory of the Royal Biological Institution at Dahlem, near Berlin, consists of a review of the literature on derris, more than 75 references to which are included.

The analysis of derris roots and the estimation of the rotenone content, D. R. KOOLHAAS (*Bul. Jard. Bot. Buitenzorg*, 3 ser., 12 (1932), No. 3-4, pp. 563-574, fig. 1).—The author has found the rotenone content of derris root to show wide variation not only when the different varieties are mutually compared but also when different plants of one variety are compared. The rotenone content does not always show a maximum for derris roots at the age of 23-24 months. The rotenone content is lower for very fine roots than for more coarse roots, the rotenone being principally located in the wood. There is said to be no relation between the rotenone content and the ether extract. Three derris roots were found with an extremely high rotenone content, namely, 12, 10.6 and 10.6 percent, respectively.

Rotenone: Its insecticidal value, J. M. GINSBURG (*New Jersey Stat. Circ.* 273 (1933), pp. 2).—A brief practical statement.

Pyrethrum: Its value in exterminating insects, J. M. GINSBURG (*New Jersey Stat. Circ.* 272 (1933), pp. 4).—A practical summary of information.

The preparation and properties of pentathionic acid and its salts: Its toxicity to fungi, bacteria, and insects, O. N. LIMING (*Phytopathology*, 23 (1933), No. 2, pp. 155-174, fig. 1).—In tests of the value of pentathionic acid as an insecticide, three common species of plant lice, the bean aphid, the cotton or melon aphid, and the spiraea aphid (*Aphis spiraeicola* Patch), were used. The results of the preliminary tests indicate that this acid is very toxic to plant

lice, or about one third as toxic as nicotine sulfate to the melon aphid and equal to the nicotine spray in the control of *A. spiraeicola*.

In preliminary tests made by H. F. Dietz, a 0.5 percent solution of the acid was capable of killing earthworms in one hour, it comparing favorably with pyrethrum in the time required.

Oil spray investigations (Oregon Sta., Hood River Branch Sta. [Pamphlet, 1933], p. 6).—In a brief summary of results obtained at the Hood River Substation during the past decade, it is pointed out that in dormant applications certain oil sprays were found unsafe during the critical period of bud development while others are safe but not quite so efficient. In summer sprays oils were found to be of questionable adaptability. Newtown apples were found to be highly susceptible to oil injury. In 6-year tests oil used with arsenate of lead has not materially improved control and has complicated washing practices.

The biological control of sugar cane pests, W. R. THOMPSON (Indian Jour. Agr. Sci., 2 (1932), No. 4, pp. 409-417).—This contribution was presented at the Imperial Sugar Cane Research Conference held at London in 1931 (E.S.R., 66, p. 824).

[Contributions on fruit insects and their control, etc.] (Mass. Fruit Growers' Assoc. Rpt., 38 (1932), pp. 21-25, 27-29, 128-142, 154-156, 158-164, 178, 182-184).—The contributions presented at the annual meeting of the Massachusetts Fruit Growers' Association (E.S.R., 67, p. 427) held in January 1932 include the following: The Oriental Fruit Moth (pp. 21-25, 27-29) and Notes on the Control of the Apple Leafhoppers [the Rose Leafhopper, Apple Leafhopper, Potato Leafhopper, *Typhlocyba pomaria* McAtee, and *Erythroneura obliqua* Say] in Connecticut (pp. 128-132), both by P. Garman; Control Studies of Apple Maggot in 1931, by A. I. Bourne and W. H. Thies (pp. 133-137); Relation of Temperature to the Activity of the Plum Curculio, by W. D. Whitcomb (pp. 138-142); Spray Materials and the Residue Problem, by O. C. Roberts and A. I. Bourne (pp. 154-156, 158-161); Summary of Orchard Insect Pests in 1931, by A. I. Bourne (pp. 162-164); Results of the New England Apple Maggot Conference, by R. A. Van Meter (p. 178); Revision of the Partridge Damage Law, by C. H. Gould (pp. 182-184); and Report of Orchard Pest Committee, by H. Gilmore (p. 184).

[Contributions on avocado insects and their control] (Calif. Avocado Assoc. Yearbook 1932, pp. 38-43, 46-48).—Three contributions from the California Citrus Experiment Station are here presented: The Trend of Avocado Pests and Their Control (pp. 38, 39), Control of Avocado Scale (pp. 40-43), and Progress Report on Avocado Insect Pest Investigations (pp. 46-48), all by H. J. Quayle.

Insect pests of citrus and their control, S. W. CLARK (Texas Sta. Circ. 67 (1933), pp. 40-49, figs. 8).—The insects mentioned as of major importance as enemies of citrus in the Lower Rio Grande Valley of Texas include the California red scale, purple scale, rust mite, fire ants, chaff scale, and red spiders. Insects of minor importance referred to include the long or Glover's scale, cottony-cushion scale, soft brown scale, and several other forms.

[Annual report of the Indian Lac Research Institute for the year 1931-32], P. M. GLOVER (Indian Lac Res. Inst. Ann. Rpt. 1931-32, pp. 44, pls. 6).—Included in this report (E.S.R., 66, p. 154) are accounts of pests of lac host trees (pp. 15-20), of the bionomics of the lac insect (*Laccifer (Tachardtia) lacca* Kerr) (pp. 20-23), of predators (pp. 23-27) and of parasites (pp. 27, 28) of the lac insect, and of the control of lac insect enemies (pp. 29-36).

[Contributions on insects attacking shade and ornamental trees] (Natl. Shade Tree Conf. Proc., 8 (1932), pp. 23-31, 70-81, 89-93).—The entomological contributions presented at the eighth annual meeting of the National Shade Tree

Conference, held at Rochester, N.Y. (E.S.R., 67, p. 565), include the following: *Some Conditions Leading to the Attack of Shade and Ornamental Trees by Borers*, by W. Middleton (pp. 23-31); *The Relation of Gipsy Moth Control to the Shade Tree Problem*, by A. F. Burgess (pp. 70-76); *Shade Tree Insects in 1932*, by E. P. Felt (pp. 76-81); and *Studies of Some Insects of Evergreens*, by F. L. Gambrell (pp. 89-93).

The fumigation of stored products affected by insects, J. W. MUNRO (*Jour. Roy. Sanit. Inst.*, 53 (1933), No. 10, pp. 578-582).—A general discussion.

Biennial report of the State entomologist for 1929-1930, M. S. YEOMANS ET AL. (*Ga. State Bd. Ent. Bul.* 75 (1931), pp. 52).—The work under way during the biennium 1929-30 is reported upon.

[Contributions on economic insects in Hawaii] (*Hawaii. Ent. Soc. Proc.*, 8 (1932), No. 1, pp. 37-39, 111-120, 127-140, 163-190, 193-195).—Contributions relating to economic insects here presented are as follows: *Some Effects of Pseudococcus brevipes* (Ck1.) on Pineapple Fruit, by W. Carter and K. Ito (pp. 37-39); *Hymenopterous Parasites of the Coccidae, etc., in Hawaii*, by D. T. Fullaway (pp. 111-120); *The Host Trees of the Endemic Cerambycidae in Hawaii*, by O. H. Swezey (pp. 127-140); *The Economic Importance of the Mediterranean Fruit Fly to Hawaiian Horticulture*, by A. C. Mason (pp. 163-178); *Some Observations on Forest Insects at the Nauhli Nursery and Vicinity on Hawaii*, by O. H. Swezey and F. X. Williams (pp. 179-190); and *Notes on a Small Collection of Philippine Weevils That Feed in the Fleshy Receptacles or "Fruits" or Wild Figs*, by F. X. Williams (pp. 193-195).

[Contributions on economic insects and their control in Illinois] (*Ill. State Hort. Soc. Trans.*, 66 (1932), pp. 150-163, 168-172, 307-310, 376-379, 541-548, figs. 2).—These contributions include the following papers: *Advances in Codling Moth Control*, by W. P. Flint (pp. 150-163); *Codling Moth Bands*, by M. D. Farrar (pp. 168-172); *Observations on Orchard Insect Pests in Northern Illinois for the Season of 1932* (pp. 307-310) and *Suggestions for Insect Control on Vegetable Crops* (pp. 376-379), both by L. H. Shropshire; *Adapting Northwest Codling Moth Control Methods to Midwest Conditions*, by R. Dorman (pp. 541-543); and *Suggestions for Codling Moth Control*, by D. E. Lewis (pp. 543-548).

[Report of work in entomology at the Maine Station] (*Maine Sta. Bul.* 363 (1932), pp. 266-270, 301, 302, fig. 1).—The work of the year, progress in which is reported upon, includes that with blueberry pollination, by C. R. Phipps, F. B. Chandler, and I. C. Mason; wireworms, by J. H. Hawkins; apple fruit fly or railroad worm, by Phipps; insects in relation to virus diseases of potatoes, by G. W. Simpson; and the apple maggot, by Phipps.

[Report of work in insect control at the New Hampshire Station] (*New Hampshire Sta. Bul.* 270 (1933), pp. 11, 12).—Brief reference is made to work aimed at the development of new contact insecticides and the control of the apple maggot, by W. C. O'Kane, and at the reduction of spray residue, by G. P. Percival and G. F. Potter.

[Contributions on economic insects and their control in Virginia] (*Va. State Hort. Soc. Rpts.* 36 (1931), pp. 134-138, 150-161, 164-169, 207-213 fig. 1; 37 (1932), pp. 73-82, 85-92, 147-157, 170-181, figs. 5).—The entomological contributions presented at the annual meeting of the Virginia State Horticultural Society held in Winchester in December 1931 (E.S.R., 67, p. 283), include the following: *Can Codling Moth Be Controlled by Arsenical Sprays?* by W. S. Hough (pp. 134-138); *Importance of Bees in Pollination*, by E. F. Phillips (pp. 150-161); and *What to Expect from the Oriental Fruit Moth in 1932*, by L. R. Cagle (pp. 164-169). In the appended proceedings of the Virginia Bee-

keepers Association, contributions are presented on Causes of Fermentation of Honey, by E. F. Phillips (pp. 207-212), and Bees for Orchards, by C. W. Cary (pp. 212, 213).

The contributions presented at the 1932 meeting include the following: The Scale Menace to Virginia Orchards, by T. W. Ayers (pp. 73-76); The Scale Menace to Virginia Orchards, by A. H. Teske (pp. 76-82); Spraying for Apple Leafhoppers, by W. J. Schoene (pp. 85-88); Developments in Codling Moth Control, by W. S. Hough (pp. 88-92); The Place of Stationary Spray Outfits in Virginia, by H. H. Gordon (pp. 147-157); and The Japanese Beetle in Virginia, by C. H. Hadley (pp. 170-181).

The insects of Japan illustrated, T. ESAKI, H. HORI, ET AL. (*Nippon Konchu Zukan. Iconographia Insectorum Japonicorum. Hokuryukan, Tokyo, 1932, pp. [6]+97+123+[2]+15+[2241+39], pls. 24, figs. 4440; Sup., pp. [2+70+2], figs. 54; rev. in Jour. Econ. Ent., 25 (1932), No. 5, pp. 1117, 1118*).—This double column octavo work, prepared by 26 of the leading entomological specialists in Japan, describes and illustrates more than 4,000 species of insects inhabiting Japan and Taiwan. The work includes, first, a 97-page scientific index, followed by a 123-page Japanese index. A table of the orders of insects, next presented, is followed by the main body of the text, which takes up the orders of insects, two species being illustrated side by side on each page, a detailed account in Japanese being given beneath each figure. The work concludes with 24 colored plates of insects, of which 2 each are devoted to eggs, larvae, and pupae. The review is by C. P. Alexander.

Studies on aster yellows in some new host plants, L. O. KUNKEL (*Contrib. Boyce Thompson Inst., 3 (1931), No. 1, pp. 85-123, figs. 50*).—The author reports the experimental transmission of aster yellows to 120 new host species, representing 30 different families of plants, the most striking symptoms of each host plant being described. The disease was carried to all host plants except the tomato by means of the six-spotted leafhopper. It was not transmitted mechanically by means of juice from diseased tissues to any plant, but was transferred to the tomato by budding. The disease was not transmitted to potato, tobacco, peach, celery, and *Zinnia elegans* after repeated exposure to virus-bearing colonies of the six-spotted leafhopper.

Insect transmission of peach yellows, L. O. KUNKEL (*Contrib. Boyce Thompson Inst., 5 (1933), No. 1, pp. 19-28, figs. 3*).—In experimental work extending over a 5-year period peach yellows was transmitted to seven young seedling peach trees by the leafhopper *Macropsis trimaculata* (Fitch), about 10 percent of the trees exposed to this leafhopper having become diseased. The disease was not transmitted by the green peach aphid, black peach aphid, tarnished plant bug, peach borer, mealybugs (the citrus mealybug and long-tailed mealybug), froghopper (*Philaenus leucophthalmus* (L.) var. *pallidus* (Zett.)), treehoppers (*Thelia bimaculata* (Fab.) and the buffalo treehopper), or leafhoppers (*Graphocephala coccinea* (Forst.), the rose leafhopper, *Jassus olitorius* Say, *Fieberiella flori* (Stal.), or *Erythroneura obliqua* Say). It had previously been shown that the six-spotted leafhopper, which is known to transmit aster yellows to a large number of different plants including one species belonging in the Rosaceae, is unable to transmit aster yellows to the peach and is probably not a vector of peach yellows (see above).

Morphological and cytological studies on the salivary glands and alimentary tract of *Cicadula sexnotata* (Fallen), the carrier of aster yellows virus, I. D. DOBROSOKY (*Contrib. Boyce Thompson Inst., 3 (1931), No. 1, pp. 39-53, figs. 7*).—A comparative morphological and cytological study of virus-free and virus-bearing individuals of the six-spotted leafhopper, shown by Kunkel (see above) to transmit the virus of aster yellows, did not reveal the presence

of any organism that could be associated with the transmission of the virus of aster yellows by this insect.

Transmission of bean-mosaic virus by insects, W. J. ZAUMEYER (*Phytopathology*, 23 (1933), No. 1, p. 40).—Under controlled greenhouse conditions the virus of bean mosaic is said to have been transmitted by feeding virus-free aphids on mosaic infected beans for from 24 to 30 hours and then transferring the insects to healthy plants. In addition to the potato aphid, the bean aphid, and the green peach aphid, shown by other investigators to be vectors, the following aphids were found by the author to transmit the virus also: The pea aphid, melon aphid, cabbage aphid, chenopodium aphid (*Hyaloapteris atrifolia*), and an aphid (*Macrosiphum ambrosia*) common on wild Compositae. All these species, except *M. ambrosia*, have been found on beans in the field.

The efficiency of traps in controlling the European earwig, *Forficula auricularia* Linn., in British Columbia, G. BEALL (*Bul. Brooklyn Ent. Soc.*, 27 (1932), No. 5, pp. 231-238, fig. 1).—The author found that trapping on a single lot caused some lowering of the level of population of the European earwig, but that the rapid infiltration from surrounding nontrapped lots nullified these results on the whole.

The thrips situation in southern California, E. A. MCGREGOR (*Calif. Citrogr.*, 18 (1933), No. 5, pp. 128, 160, figs. 2).—This is a discussion of the occurrence and control of the citrus thrips in southern California, where during the last two or three years a much larger percentage of citrus has been attacked, with a noticeable increase in the extent of grade reduction of fruit.

[Contributions on the gladiolus thrips, *Taeniothrips gladioli*] (In *New England Gladiolus Year Book 1933*. [Ashland, Mass.: C. W. Brown, Sec.], 1933, pp. 113-123, 124).—Contributions on *T. gladioli* are as follows: "Thrip-Resistant" Varieties, by E. Seeley (p. 113); The Gladiolus Thrips, by C. A. Weigel (pp. 114-116); The Menace of Thrips, by H. O. Evans (pp. 117-119); Combating Gladiolus Thrips, by W. D. Whitcomb (pp. 119, 120); Some Problems of Thrip Control, by F. C. Hornberger (pp. 120, 121); Successful Methods of Controlling Thrip, by B. Steffanson (pp. 121, 122); Recommendations for the Control of Thrip, by A. G. Dustan (p. 122); Thrip Will Be Controlled, by C. E. F. Gersdorff (pp. 122, 123); and Throttling the Thrip, by A. A. Arenius (p. 124).

The Cydnidae and Pentatomidae of Cuba, H. G. BARBER and S. C. BRUNER (*Jour. Dept. Agr. Puerto Rico*, 16 (1932), No. 3, pp. 231-284, pls. 3, fig. 1).—This is a synopsis of the Cydnidae and Pentatomidae of Cuba. Notes on their occurrence include descriptions of two new species of Cydnidae, a new genus (*Praepharnus*), and nine new species of Pentatomidae.

The grape leafhopper in California, with special reference to its control, S. LOCKWOOD (*Calif. Dept. Agr. Mo. Bul.*, 21 (1932), No. 10-11, pp. 375-393, figs. 9).—This is a summarized account of the biology, economic importance, and control of the grape leafhopper, which has been responsible for loss to vineyardists over a major portion of the grape-growing regions of the United States and Canada. It has been particularly abundant in the San Joaquin Valley since 1920.

Blossom-blight of mangos in the Philippines, F. B. SERRANO and M. A. PALO (*Philippine Jour. Sci.*, 50 (1933), No. 3, pp. 211-277, pls. 17).—This is a report of studies of an affection of the mango known as blossom blight, which is caused by the leafhoppers *Idiocerus clypealis* Léth. and *I. nivosus* Léth., thus far the most destructive and most common pest of mangoes known in the Philippines. It has been observed to attack all the different varieties of mangoes, all being equally susceptible to the infestation under more or less identical conditions.

An application of a nicotine soap solution containing 0.36 percent of soap and 0.12 percent of Blackleaf 40 (nicotine sulfate) proved to be the most effective and most economical for spraying the carabao variety. For the pico variety, which seems to possess a more delicate blossom, a solution containing 0.3 percent of soap and 0.05 percent of Blackleaf 40 showed the best results. In places where there was a lack of water supply, light trapping as a means of minimizing the ravages, particularly of the large species *I. niveosparvus* Léth., was used to advantage.

Two new genera and species of Aphididae (Homoptera), A. A. GRANOVSKY (*Ent. Soc. Wash. Proc.*, 35 (1933), No. 3, pp. 29-43, pl. 1).—Contributing from the Minnesota Experiment Station, the author erects the genera *Hoplochaitophorus*, of which *Chaitophorus quercicola* Mon. is the genotype, and *Lachnochaitophorus*, of which *L. querceus* n.sp., collected on *Quercus velutina* and *Q. borealis* at Egg Harbor, Wis., is the genotype. *L. bisselli*, which inhabits the small twigs and leaf petioles of *Q. nigra* and is always associated with ants, *Crematogaster lincolata*, from Thomasville, Ga., is described as new.

The green peach-aphis (*Myzus persicae* Sulz.) and a new pyralid mango defoliator (*Orthaga mangiferae* n. sp.), C. S. MISRA (*Indian Jour. Agr. Sci.*, 2 (1932), No. 5, pp. 536-541, pls. 3, fig. 1).—The author records the sudden appearance of the green peach aphid and its serious injury to fruit trees in north Bihar, where it had not been recorded heretofore, followed by as sudden disappearance. A descriptive and preliminary account of *O. mangiferae* n.sp. on mango trees follows.

The oak scale and its parasite, H. M. NICHOLLS (*Tasmanian Jour. Agr.*, 4 (1933), No. 1, pp. 24-26, fig. 1).—This is an account of the pit-making scale, *Asterolecanium variolosum*, of the imported European oak and the status of its hymenopterous parasite *Habrolepis dalmanni*. The latter, the only known internal parasite of this scale, was introduced from America and liberated on oak trees in the neighborhood of Christchurch, New Zealand. It is said that this parasite has now become established and is doing effective work in checking ravages of the scale.

Elimination of natural mortality as a factor in determining the effectiveness of hydrocyanic acid gas on the California red scale, F. S. STICKNEY and H. R. YUST (*Jour. Agr. Res. [U.S.]*, 46 (1933), No. 5, pp. 437-447, figs. 2).—This contribution reports upon work conducted with a view to determining the amount of fluctuation that may be expected in natural mortality of the California red scale.

The authors found that on untreated lemon fruits infested with the California red scale the number of dying female scales of the three later stages, taken separately or collectively, bears a nearly constant ratio to the number of living plus dying scales, irrespective of a large number of varying factors commonly encountered in practice. This ratio, considered as indicating natural mortality, can be assumed to be equal to approximately 4 per cent, at least for the period and locality covered. Natural mortality as thus expressed can be eliminated as a factor in determining the effectiveness of hydrocyanic acid gas treatments with closer accuracy than by the familiar method of estimating it from the ratio of living scales to the total scale count (including dead, dried specimens).

What butterfly is that? A guide to the butterflies of Australia, G. A. WATERHOUSE (*Sydney: Angus & Robertson*, 1932, pp. [8]+291, pls. 34, figs. 4).—This work, which has been prepared with a view to ready identification of the butterflies of Australia, some 339 in number, includes brief descriptions and plates with colored illustrations by N. W. Cayley.

Researches on the urticant spines of caterpillars [trans. title], P. R. TONKES (*Bul. Biol. France et Belg.*, 67 (1933), No. 1, pp. 44-99, pla. 3).—This contribution is presented in connection with a three-page list of references to the literature.

Studies on chemical changes during the life cycle of the tent caterpillar (*Malacosoma americana* Fab.).—V, Weight and data, W. RUDOLFS (*Jour. N.Y. Ent. Soc.*, 40 (1932), No. 4, pp. 481-488, fig. 1).—In this further contribution from the New Jersey Experiment Stations on the chemical changes taking place in the life cycle of the eastern tent caterpillar (E.S.R., 61, p. 661), the author reports upon the size, weight, and chemical constituents of its several stages, the details being presented in tabular form.

Biology of the bidens borer, *Epiblema otiosana* (Clemens) (Lepidoptera, Olethreutidae), G. C. DECKER (*Jour. N.Y. Ent. Soc.*, 40 (1932), No. 4, pp. 503-509, fig. 1).—This contribution from the Iowa Experiment Station reports upon a lepidopteran generally regarded as of little economic importance. It is, however, of considerable interest, being an important enemy of a group of noxious weeds known as beggar-ticks and also serving as a reservoir for important parasites of several injurious insects.

On the biology of the species of *Chrysoclista* infesting hawthorn, M. MILES (*North West. Nat.*, 7 (1932), No. 4, pp. 294-298, pl. 1).—This contribution relates to two forms or species of moths of the genus *Chrysoclista*, one known as the apple shoot and the other as the hawthorn fruit form. The former emerges during the latter part of July and is on the wing until mid-August, while the hawthorn fruit form is on the wing mainly in June. The eggs of the hawthorn form are laid on the fruits, while those of the apple form are laid on the twigs, usually in the leaf axils. The larva of the hawthorn *Chrysoclista* tunnels almost immediately into the fruit and feeds on the pericarp; the larva of the apple *Chrysoclista* tunnels into the twig and feeds on the woody tissue.

Biology and morphology of the spindle worm, or elder borer, J. C. SILVER (*U.S. Dept. Agr., Tech. Bul.* 345 (1933), pp. 20, figs. 9).—Reports that *Achatodes zeae* Harr. was attacking corn, the larvae being sometimes mistaken for the European corn borer, led to the investigations of it conducted from the European corn borer laboratory at Toledo, Ohio. This noctuid at times seriously injures several species of elder but very rarely injures corn. The larval period is of short duration, being usually confined to uneconomic plants. Natural control by several species of parasites and by birds and rodents usually holds it in check. It is pointed out that the eggs are easily destroyed during the fall and winter months by burning the old, dead elder wood to which they are attached.

Spraying for codling moth control, H. N. WORTHLEY (*Pennsylvania Sta. Bul.* 285 (1933), pp. 16, figs. 4).—This is a report of the results of spraying experiments for the control of the codling moth conducted in the heavily infested apple orchards of Adams County during the seasons of 1931 and 1932.

"A petal-fall and four first-brood cover sprays gave the most promise of killing enough first-brood larvae to reduce heavy second-brood attack. Arsenate of lead at less than 3 lb. to 100 gal. was useless in a heavy codling moth infestation, even with a casein spreader and sticker added. On Grimes sprayed last on July 30 even a reduced dosage of arsenate of lead produced excessive arsenical residue. Sprays timed for the second brood of larvae would have been applied in mid-August. The addition of hydrated lime to the standard spray mixture containing arsenate of lead at 3 lb. to 100 gal. resulted in greatly reduced effectiveness. The addition of fish oil at 1 qt. to 100 gal. increased the

effectiveness of the spray. The use of a miscible oil to replace a portion of the arsenate of lead did not yield satisfactory results. Nicotine tannate as a substitute for arsenate of lead was unpromising. Arsenate of lead at standard strength in a schedule of four first-brood cover sprays, and at reduced strength in a late July spray, resulted in 50 percent reduction in codling moth population in 1932, as compared with 1931. The petal-fall application was as valuable as any cover spray in codling moth control. With the possible exception of the first cover spray, all the applications, as timed by codling moth catch in bait pails, resulted in increased control."

Cocoon parasites of the oriental fruit moth, B. F. DRIGGERS (*Jour. N.Y. Ent. Soc.*, 40 (1932), No. 4, pp. 489-496).—Reporting upon studies conducted at the New Jersey Experiment Stations the author calls attention to the fact that the work on parasites of the oriental fruit moth has dealt largely with those species which attack the egg and feeding larva, little attention having been given to the species attacking the cocoon stages.

"Studies carried on in New Jersey from 1928 to 1930 show (1) that a high percentage of parasitism may be found in overwintering hibernacula collected in the spring, (2) that for the most part the species encountered are not the same as those found attacking the egg or feeding larval stages, and (3) that the majority of this parasitism takes place after the cocoon is formed or during the process of cocoon formation."

The life history and control of the oriental fruit moth, C. H. ALDEN and W. H. CLARKE (*Ga. State Bd. Ent. Bul.* 74 (1931), pp. 23, figs. 6).—The life history of the oriental fruit moth at Fort Valley, Ga., in 1925 and 1926 (pp. 11, 12) and at Thomaston, Ga., in 1930 (pp. 12-16) is given particular attention in this account.

A contribution to the study of the genera *Epehestia* Gn. (including *Strymax* Dyar) and *Plodia* Gn. (Lepidoptera, Phycitidae), with notes on parasites of the larvae, O. W. RICHARDS and W. S. THOMSON (*Ent. Soc. London, Trans.*, 80 (1932), pt. 2, pp. 169-250, pls. 8).—This contribution, which includes descriptions of 4 new species, is presented in connection with a 16-page list of references to the literature.

Cacao beans and *Epehestia elutella*, R. V. WADSWORTH (*Trop. Agr. [Trinidad]*, 10 (1933), No. 4, pp. 97-100).—The author has found that the cacao bean properly fermented and with its shell intact is proof against the attack of *E. elutella*. The damage caused by this pest is due to the presence of defective beans in the parcel, including partially cracked, germinated, and broken beans. Cut and unfermented beans are also a source of infestation.

Life history of the Angoumois grain moth in Maryland, P. SIMMONS and G. W. ELLINGTON (*U.S. Dept. Agr., Tech. Bul.* 351 (1933), pp. 35, figs. 10).—Following a brief introduction the authors consider the Angoumois grain moth as it occurs in Maryland (pp. 2-14), its life history, the details of which are presented in tabular form (pp. 14-31), its parasites (p. 31), and outbreaks in the past and future (pp. 31, 32). The report is based upon studies commenced in May 1923 in Montgomery County and continued until the close of the summer of 1927, preliminary accounts having been noted (*E.S.R.*, 51, p. 159; 53, p. 454; 57, p. 361; 63, p. 461).

The Angoumois grain moth survives the period of unfavorably cold weather, about 6 months in Maryland, for the most part as larvae enclosed in kernels of grain in storage and in scattered wheat in litter, straw piles, and baled straw. The winter mortality, however, appears to be high, and there is no survival in planted wheat. The adults commence to emerge about the middle of May, and some of those which appear before the wheat harvest fly to the fields to deposit eggs upon the developing grain. Later, the harvested grain is attacked, both

before and after threshing. The second brood of adults appears soon after wheat harvest, which begins in late June or early July, infestation increasing most rapidly during July and August.

Of the influences that antagonize the species, parasites are relatively unimportant. Since the young larvae are able to establish themselves on wheat before the plant has blossomed and even before the heads appear, clean-up operations to reduce moth sources on farms should be completed before the wheat is headed, preferably before May 1. Such field infestation arises from wheat in bins, litter, and straw, and from stored ear corn.

Although infestations of standing wheat expressed as percentages usually are small, they represent large populations per acre. Upon this widespread field infestation depends the ability of the insect to cause commercial damage. Infestation of field corn at harvest time is general but light, being confined for the most part to the exposed tips of ears grown near sources of moths in and about farm buildings.

In hot weather the eggs hatch after an incubation period of from 4 to 8 or more days, the newly hatched larva boring into the host seed within a short time and thereafter feeding entirely within the grain. Pupation takes place in a silken cocoon constructed in the cavity which results from larval feeding. The development of the insect, from hatching to emergence, may be completed in as short a time as 29 days, but longer developmental periods are the rule, and the rapidity of the growth and metamorphosis of individuals which hatch on the same day varies markedly. The temperature within which reproduction occurs is from 64° to 95° F.

An unusual invasion of the clothes moth, *Tineola bisselliella* (Lepid.: Tineidae), G. W. HERRICK (*Ent. News*, 44 (1933), No. 4, pp. 99-101).—The author records a case in which an infestation of raw wool in a warehouse by the webbing clothes moth resulted in spread of the pest to residences in the neighborhood.

Clothes moths and house moths: Their life-history, habits, and control, E. E. AUSTEN and A. W. MCK. HUGHES (*Brit. Mus. (Nat. Hist.), Econ. Ser. No. 14* (1932), pp. 56, figs. 20).—This, a practical compilation of information presented with references to the literature, includes an index to the subject matter.

The duration of Eulan protection against the webbing clothes moth, I [trans. title], A. HASE (*Anz. Schädhugsk.*, 8 (1932), No. 7, pp. 73-82, figs. 5).—The genuine protection of woolen from moth injury for longer than 10 years through impregnation with Eulan F is reported.

Experimental studies on the influence of low temperatures upon the development of paddy borer (*Schoenobius incertellus* Walk.).—First report [trans. title], K. SHIBATA (*Jour. Soc. Trop. Agr. (Nettai Nōgaku Kwaishi)*, 4 (1932), No. 4, pp. 504-516, figs. 2; *Eng. abs.*, p. 516).—In studying the resistance of *S. incertellus*, one of the most serious pests of the rice plant in Japanese territory, larvae and pupae were found to be injured by sudden exposure to a low temperature.

Larval instars and feeding of the black cutworm, *Agrotis ypsilon* Rott., A. F. SATTERTHWAIT (*Jour. Agr. Res. [U.S.]*, 46 (1933), No. 6, pp. 517-530, figs. 3).—Outbreaks of the black cutworm in the overflow land of the Black River in the neighborhood of Hoxie, Ark., following inundations that affected thousands of acres of cornland in 1927 and 1928, led to the studies here described which include experimental work at Webster Groves, Mo.

There were found to be three generations of the black cutworm a year at Webster Groves. "The growth of larvae in general, judged by head measurements, is approximate to one and a half times the size of the preceding head

width, if the growth is completed in six instars. Where more instars occur, the increase after the sixth is greatly reduced for the subsequent stages. Increases in size between instars, especially in the first three, may be much greater; rarely the width in the second instar measures twice the width in the first.

"The quantities of food eaten in the first three instars are small, then increase abruptly, especially between the fifth and sixth instars, in the individuals maturing in six instars. The measurement of food eaten was possible when corn foliage alone was supplied. In nature, the larvae bite off and then discard entire plants, thus getting an unknown volume of plant tissue and wasting perhaps a thousand times more than they consume. When fed corn foliage exclusively, a larva which undergoes six instars will eat the equivalent of 65 sq. in. of corn leaf. The feeding of the larvae which eventually yield females is appreciably heavier than that of larvae which yield males, and is lighter in the July than in the May brood."

Notes on the biology of *Laphygma exigua* Huebner, J. W. WILSON (*Fla. Ent.*, 16 (1932), No. 3, pp. 33-39).—This is a contribution from the Florida Experiment Station reporting upon observations of the life history and habits of the beet armyworm, the most important enemy of the asparagus fern in Florida, occurring from Auburndale north. Injury is caused by the first and second instar larvae, which climb to the tip of the asparagus shoot and feed on the tender bud, causing it to curl over and eventually to wither. The older larvae feed on any part of the plant, preferring the soft succulent syrays which have just finished expanding. The average length of the life cycle of six generations was 24 days. Of eight parasites observed, *Chelonus texanus* Cress. was by far the most abundant.

Life-histories of Indian Microlepidoptera (second series): *Alucitidae* (Pterophoridae), Tortricina, and Gelechiadae, T. B. FLETCHER (*Imp. Council Agr. Res. [India], Sci. Monog.* 2 (1932), pp. 58, pls. 35).—This second series (see page 373) deals with the life histories of species of moths belonging to the families Alucitidae, Tortricidae, and Gelechiidae.

Anopheline mosquitoes in Southern Rhodesia, 1926-1928, H. S. JESON (*London School Hyg. and Trop. Med. Mem.* 4 (1931), pp. IX+55, pls. 15, figs. 10).—This is a report of investigations of mosquitoes made during the course of studies of black-water fever by G. R. Ross.

Anopheles walkeri Theobald as a vector of *Plasmodium vivax* Grassi and Feletti, R. MATHESON, M. F. BOYD, and W. K. STRATMAN-THOMAS (*Amer. Jour. Hyg.*, 17 (1933), No. 2, pp. 515, 516).—The authors have found *A. walkeri* to be an efficient definitive host for *P. vivax*.

Hydrodynamics of mosquito breeding places, P. I. DE JESUS (*Amer. Jour. Hyg.*, 17 (1933), No. 2, pp. 502-514, figs. 2).—A study of the hydrodynamics of a typical *Anopheles minimus* breeding place showed that the maximum occurrence and intensity of larvae are found in portions of the stream with low velocity. In a number of malarial localities *A. minimus* was found breeding in stagnant seepage pools and surface wells, showing that it is not confined entirely to flowing water.

The hydrogen-ion concentration as a factor concerned in the breeding of mosquito larvae, A. A. ALBANESE (*Magyar Biol. Kutató Intézet Munkái* (Arb. Ungar. Biol. Forsch. Inst.), 5 (1932), pp. 168-176, figs. 2).—The author has found that larvae of the malaria mosquito *Anopheles maculipennis* are more sensitive to variations of the water reaction than are those of the house mosquito *Culex pipiens*. "It may be stated that although *C. pipiens* larvae were found to breed in waters of a wide pH range, the fact that 90 percent of this

group are in the region pH 7.90 to 8.59 points to a limited toleration, or a restricted preference, of this species to the reaction of the breeding waters. There is evidence that the alkalization of breeding water containing larvae in the laboratory is caused by the larvae themselves, and that the rate of hydrogen-ion decrease is greater for the *C. pipiens* as a group."

It is concluded that the pH index of the breeding water is of some bionomic importance both for the presence and development of mosquito larvae.

The effect on *Culex* larvae of paris green diluted with charcoal and notes on the feeding habits of *Culex quinquefasciatus*: Larvicide studies, V. P. F. RUSSELL and A. P. WEST (*Philippine Jour. Sci.*, 49 (1932), No. 4, pp. 651-675, pls. 3, fig. 1).—In continuation of larvicide studies (E.S.R., 68, p. 644), the authors found that charcoal at the rate of 99 parts to 1 part of paris green is an effective larvicide against *Culex* mosquitoes in laboratory containers and in a still pond. It was found that the larvae of *C. quinquefasciatus* feed at the surface, below the surface, and at the bottom of shallow water. It appears that paris green, if supported by charcoal and kept afloat, will not only destroy all *Anopheles* larvae but will kill a high percentage of *C. quinquefasciatus* larvae as well.

An investigation on petroleum oils for malaria control purposes, G. C. RAMSAY and J. A. CARPENTER (*Rec. Malaria Survey India*, 3 (1932), No. 2, pp. 203-218).—A report of studies conducted at Syriam, Rangoon, and in the South-eastern Shan States during January and February 1932.

The geographical distribution of the yellow fever vectors, H. W. KUMM (*Amer. Jour. Hyg., Monog. Ser. 12* (1931), pp. III+110, figs. 19).—This is a compilation of material recorded in the literature, unpublished communications, and certain collections made by the author in Nigeria, West Africa. The data are presented in connection with a bibliography of 320 titles and illustrated by 19 outline maps.

The adaptation of mosquito larvae to salt water, V. B. WIGGLESWORTH (*Jour. Expt. Biol.*, 10 (1933), No. 1, pp. 27-37, figs. 2).—It was found in yellow-fever mosquito work that larvae reared in fresh water were unable to withstand very high concentrations of salt water, but could by gradually increasing the concentration be made resistant to 1.1 percent sodium chloride and to "sea water" equivalent to 1.75 percent sodium chloride.

***Dasyneura leguminicola* (Lint.), the clover seed midge, M. E. METCALFE** (*Ann. Appl. Biol.*, 20 (1933), No. 1, pp. 185-204, pl. 1, figs. 2).—The author has found that the clover seed midge destroying clover seed in England, which is the same as that common in the United States, is typically two-brooded, the second brood overwintering in the larval stage. The varieties of red clover tested were found to be susceptible to attack, white clover being resistant. The author suggests that unless a resistant variety can be produced, clovers grown for seed production be chosen with a view to their being in the green-head stage either before or after the time of maximum emergence of the midges. It is pointed out that if cutting of the first crop is used as a means for destroying the second brood of midges this should take place within 10 days of the crest of emergence.

A list is given of 36 references to the literature.

Control of crane fly larvae (*Tipula paludosa* Mgn. and *T. oleracea* L.) by use of chemical [trans. title], H. GASOW (*Landw. Jahrb.*, 77 (1933), No. 1, pp. 69-112, figs. 4).—This contribution is presented with a list of 57 references to the literature.

Notes on the tachinid genus *Elodia* R. D., with three new species of *Elodia* and *Phorocera* (Diptera) from Japan, J. M. ALDRICH (*Ent. Soc.*

Wash. Proc., 35 (1933), No. 2 pp. 19-23).—The species *E. flavipalpis*, *E. subfasciata*, and *P. pumilio*, reared in Japan and Chosen (Korea) from larvae of the oriental fruit moth, are described as new.

Food requirements of blowfly cultures used in the treatment of osteomyelitis. J. G. HAUB and D. F. MILLER (*Jour. Expt. Zool.*, 64 (1932), No. 1, pp. 51-56, fig. 1).—In a series of experiments conducted with a view to eliminating much of the routine involved in the rearing of sterile blowfly larvae for the treatment of osteomyelitis, a diet of lean beef was found the most satisfactory of eight different types of meat foods for this purpose. Of the various diets tested for the adult flies brick sugar, fresh lean beef, and fresh water was adopted. On this diet the average length of oviposition period in a cage of flies was 30 days when the eggs were collected three times per week. This diet was used for 10 months over a period covering 10 generations and found efficient.

The nutrition of flesh fly larvae, *Lucilia sericata* (Meig.).—I, The adequacy of sterile synthetic diets, A. E. MICHELbacher, W. M. Hoskins, and W. B. HERMS (*Jour. Expt. Zool.*, 64 (1932), No. 1, pp. 109-131, pl. 1, fig. 1).—The authors describe a method of sterilizing the eggs and the larval food of the flesh fly *L. sericata* which they developed and have used in a study of the nutritional needs of the larvae. The account is presented in connection with a list of 31 references to the literature.

Notes on the life cycle of *Oestrus ovis*. W. C. MITCHELL and N. G. CORBETT (*Jour. Amer. Vet. Med. Assoc.*, 82 (1933), No. 5, pp. 780, 781).—The authors have found that the larvae of the sheep botfly develop to maturity in 2½ to 3½ months in the heads of spring lambs in western Texas and eastern New Mexico. The time required for mature larvae to pupate at ordinary room temperature varied from 12 to 72 hours, and the time required for flies to emerge from these pupae under similar conditions varied from 17 to 37 days. Flies kept in captivity lived from 4 to 32 days. It thus appears that the life cycle of the sheep botfly may be completed in lambs in 3½ to 4½ months in western Texas and eastern New Mexico.

The apple maggot, *C. R. PHIPPS* (*Maine State Pomol. Soc. Ann. Rpt. 1931*, pp. 13-20; abs. in *Maine Sta. Bul.* 363 (1932), pp. 301, 302).—This general account includes a report of dispersal work, an account of which by the author and Dirks from another source has been noted (*E.S.R.*, 67, p. 716). Dispersal studies by the station in 1932 as well as of the biology of the pest have also been noted (*E.S.R.*, 69, p. 244).

It was observed in field work that dispersal is often a gradual process, the flies migrating from tree to tree as the later varieties become more attractive. The earlier varieties, such as Red Astrachan, are most attractive at first, but after the first of August flies begin to concentrate on later varieties, such as Wealthy, Rhode Island Greening, Baldwin, Northern Spy, and Ben Davis. Both the Golden Delicious and Red Delicious varieties are quite susceptible to attack under Maine conditions.

It is pointed out that in general in well-isolated orchards containing only fall and winter varieties this insect should be readily controlled by one or two thorough and timely spray applications. If both early and late varieties are in the same planting, the drops from the early apples should be picked up and destroyed every two or three days.

Viability of eggs and larvae of the apple maggot (*Rhagoletis pomonella* Walsh) at 32° F., P. J. CHAPMAN (*New York State Sta. Tech. Bul.* 206 (1933), pp. 19, figs. 3).—The experiments reported have shown that all eggs and larvae of the apple maggot succumb when infested fruit has been exposed

to temperatures customarily maintained in fruit cold storage houses, namely, 31° to 33°. "Complete mortality is effected in about 35 days. Refrigeration is proposed as a means of disinfesting apples intended for foreign markets, since at present no tolerance on apple maggot is allowed in such fruit.

"Emergence of larvae from apples starts about July 15 to 20 and may continue into December. While a great majority of larvae in nature are exposed to mean temperatures ranging between 55° and 70° F., evidence shows that late emerging individuals may endure a considerably lower mean temperature and may survive in fruit when subfreezing air temperatures obtain. Resistance of the host to larval establishment varies with the variety of apple. In late-maturing varieties larval mortality may approach or attain 100 percent."

Life history notes and a study of the effects of humidity on adult emergence of *Rhagoletis suavis* Cress. from pupae at a constant temperature (Diptera, Trypetidae), D. E. BECK (*Jour. N.Y. Ent. Soc.*, 40 (1932), No. 4, pp. 497-501, figs. 2).—A brief account is given of observations of the walnut husk maggot (*R. suavis*) as a pest of the black walnut in Iowa.

A practical handbook of British beetles, I, II, N. H. JOY (London: H. F. & G. Witherby, 1932, vols. 1, pp. XXVII+622; 2, pp. [4]+194, pls. 170; rev. in *Nature* [London], 130 (1932), No. 3275, pp. 186, 187).—In volume 1, following a preface and introduction, the author deals at length with the classification of British Coleoptera, represented by about 3,560 species. The subject matter is presented in the form of keys to the suborders, families, subfamilies, tribes, genera, and species. Volume 2 is devoted entirely to pen drawing illustrations of their structure. Both volumes include indexes to genera, species, etc.

The review is by A. D. IMMS.

The potato *Epilachna* beetle, *Epilachna viginti-octo-punctata* (Fabr.), B. KRISHNAMURTI (*Mysore Dept. Agr., Ent. Ser. Bul.* 9 (1932), pp. 16, pls. 5).—This is a report of a study made of a coccinellid that is a serious pest of the potato, being widely distributed throughout the potato-growing areas of Mysore. In other parts of India, especially in the plains, *E. 28-punctata* and *E. dodecnotigma* occur generally on potato, brinjal, tomato, and melon.

Blister beetles and their relation to the honey bee, A. G. BELJAVSKY (*Bee World*, 14 (1933), No. 3, pp. 31-33, figs. 4).—In this account of blister beetles the author points out that the primary larvae or so-called triungulins of *Meloe variegatus* enter the interstices between the abdominal segments and between the rings of the prothorax and mesothorax, and irritate the bee to such an extent that it dies in violent convulsions. In an apiary in Russia the author has observed bees dying by the hundreds as a result of such an attack.

Biology of the flour beetles, *Tribolium confusum* Duv. and *T. ferrugineum* Fab., N. E. GOOD (*Jour. Agr. Res. [U.S.]*, 46 (1933), No. 4, pp. 327-334).—This is a preliminary account of a rather extensive experiment on two flour beetles (the confused flour beetle and the rust-red flour beetle) that are among the more serious pests of flour, meal, and other cereal products. It is pointed out that in the identification of the two species the size of the eyes on the ventral surface of the head is the best distinguishing character.

In the central and northern parts of the United States the winter is passed in the adult state, the adults of both species living two years or even longer. The oviposition period of the confused flour beetle may last as long as 14 months, the average being about 9 months. That of the rust-red flour beetle is slightly less. A female of either species usually lays 400 to 500 eggs during this time; in some cases nearly 1,000 eggs have been laid by a single female. The average incubation period at 27° C. is 6.8 days for the confused flour beetle and 5.5 days for the rust-red flour beetle. The number of larval instars

ranges from 6 to 11, with an average of 7 or 8. The larval period at 27° ranges from 27 to 90 days according to the food. It is slightly longer for the confused flour beetle than for the rust-red flour beetle. Whole-wheat flour, middlings, bran, corn meal, oatmeal, and white flour, arranged in the order of their acceptability, were the foods used in the experiments. Measurements of the head capsule in larvae of the confused flour beetle are given. The pupal period at 27° averages 8.2 days for the confused flour beetle and 7.1 days for the rust-red flour beetle. Lower temperatures lengthened all stages considerably.

Enemies of the flour beetles include the mites *Acarophenax tribolii* Newst. and Duval and *Pediculoides ventricosus* Newp. and the bethylid *Rhabdepyris zeae* Waterst.

A mathematical theory of the growth of population of the flour beetle, *Tribolium confusum* Duv.—II, The distribution by ages in the early stages of population growth, J. STANLEY (*Canad. Jour. Res.*, 7 (1932), No. 4, pp. 426-433, fig. 1).—This is in continuation of the contribution previously noted (E.S.R., 68, p. 359).

Prothetely in an elaterid larva (Coleop.), C. A. THOMAS (*Ent. News*, 44 (1933), No. 4, pp. 91-96, figs. 3).—In this contribution from the Pennsylvania Experiment Station, presented in connection with an annotated list of 23 references to the literature, the author describes a case of this unusual metamorphosis in a wireworm, the larva of *Monocrepidius lividus* DeG.

Preliminary studies of the *Syneta* beetle and its control in Oregon, J. WILCOX (*Oregon Sta. Circ. Inform.* 52 (1931), pp. 4).—This account, given in mimeographed form, is based largely upon spray tests conducted on cherries from 1925 to 1930, inclusive. Though attacking apple and pear in the Northwest, *S. albida* is of particular importance as a cherry pest, its injury to the cherry crop in recent years having been rapidly mounting, especially in parts of the Willamette Valley. Injury to some degree is caused by the larvae feeding on the roots of the trees and by the adults feeding on the buds, blossoms, and leaves. The most serious injury, however, is that inflicted on the fruit by the adults. They eat the skin and a small part of the flesh of the fruit in from small to rather large irregular patches, which are later evidenced as shallow, dark-colored scars. This fruit is unsalable and unfit for canning, and consequently the grower suffers a dockage on his weight slip corresponding to the percentage of injury to the fruit. The injury to cherries by this insect apparently occurs in cycles of several years, although the number of years in each cycle is not known. Other plants attacked to a greater or less extent are prune, quince, peach, plum, wild crab apple, hawthorn, currant, gooseberry, hazelnut, strawberry, alfalfa, alder, loganberry, black walnut, English walnut, and filbert.

Control work has shown the standard spray of lead arsenate 4 lb. to 100 gal. of water before and after blossoming to give a marked reduction in the amount of injured fruit compared with unsprayed fruit. Two sprays give better control than do either of the sprays alone. The first spray after blossoming is the most effective single spray. Two sprays after blossoming are more effective than one spray. For the preblossom spray, lead arsenate combined with a fungicide such as lime-sulfur or Bordeaux mixture does not apparently reduce the effectiveness of the lead arsenate. Dusting appears to be as effective as spraying in *Syneta* control.

Two years experience with *Syneta* beetle control, J. G. HOGG (*Oreg. State Hort. Soc. Ann. Rpt.*, 24 (1932), pp. 21-23).—A brief account of *S. albida*, the most serious enemy of the cherry industry in the Willamette Valley of Oregon,

where it has spread so rapidly in recent years that very few of the orchards are free from it. Reference is made to Oregon Experiment Station Circular of Information 52 (above noted). In control work with dusts, one consisting of 30 parts of powdered arsenate of lead and 70 parts of hydrated lime, applied at the rate of $\frac{3}{4}$ to 1 lb. per tree on April 24, when most of the petals had fallen, and again on May 4 is considered to have given the best results.

A record of winter kill of western pine beetle in California, 1932, J. M. MILLER (*Jour. Forestry*, 31 (1933), No. 4, pp. 443-446).—The author here records the sudden depletion of the western pine beetle population over a large area in the Modoc National Forest, due to a temperature a few degrees below those which normally occur in winter in that region. Following a cold spell in December 1932, 65 percent of the western pine beetle broods were found to be dead.

Temperature extremes as a factor in the ecology of the southern pine beetle, J. A. BEAL (*Jour. Forestry*, 31 (1933), No. 3, pp. 329-336).—The effect of low winter temperature and high summer temperature on the abundance of the southern pine beetle is here considered. Low winter temperatures were often found associated with termination of outbreaks of this pest, while high summer temperatures were effective only in felled exposed logs during part of the summer.

Some preliminary experiments concerning the effects of X-rays on the various stages of the bean weevil, *Bruchus obtectus* Say, G. L. HEX (*Jour. Expt. Zool.*, 64 (1932), No. 1, pp. 209-229, pls. 2, figs. 3).—The author found that, in general, the resistance of the bean weevil to X-rays rises from egg to adult, but no determinations were made to test the resistance of the newly formed pupa.

The alfalfa weevil in Colorado, J. H. NEWTON (*Colorado Sta. Bul.* 399 (1933), pp. 19, pl. 1, figs. 9).—This account deals with the discovery and history of the occurrence of the alfalfa weevil in Colorado, where its presence first became known in the spring of 1917; its host plants; appearance, habits, and life cycle; time and extent of injury; scouting method; dissemination; quarantines; and artificial and natural control. The southwestern counties in the State have remained free thus far but are in constant danger of early infestation, and careful scouting work has failed to reveal its presence in the State east of the Continental Divide. The illustrations include a colored plate showing the annual cycles of the alfalfa weevil and its parasite *Bathyplectes curculionis* Thoms.

Further studies of the physical ecology of the alfalfa weevil, *Hypera postica* (Gyllenhal), H. L. SWEETMAN and J. WEDEMAYER (*Ecology*, 14 (1933), No. 1, pp. 46-60, figs. 5).—In this further contribution from the Wyoming Experiment Station (E.S.R., 67, p. 719), the authors report having found the favorable temperature for oviposition by adults of the alfalfa weevil to be below 28° C. (82.4° F.) with relative humidities between 50 and 95 percent. "Temperatures of 30° to 37° were very injurious, especially when the relative humidity was high, while higher temperatures killed the adults in a few days. Relative humidities below 40 percent, at least with temperatures of 27° or higher, were very destructive to the adults. The favorable region for the hatching of the eggs was between temperatures of about 20° to 30° with relative humidities of 55 to 95 percent. Temperatures of 32° to 34° were unfavorable for percentage of eggs hatching, but the length of the incubation period was very short. Higher temperatures destroyed the embryos. The minimum effective temperature for incubation of the eggs was about 10°. Relative humidities below 40 percent were very destructive to the embryos. The favorable region for larval

development was between temperatures of about 20° to 30° with relative humidities ranging from 95 percent to at least as low as 30 percent. Temperatures above about 34° destroyed the larvae. The minimum effective temperature during the feeding period was near 10°, while that for the pupal period was slightly higher."

The Bremidae of Manitoba, F. NEAVE (*Canad. Jour. Res.*, 8 (1933), No. 1, pp. 62-72, figs. 3).—The author finds that the distributional ranges of many species of bumblebees meet or overlap in Manitoba. The distribution of most of these species is shown to follow closely the summer isotherms, which, in general, run in a northwest to southeast direction. In all, 23 species of bumblebees are reported from the Province.

The biology of parasites and predators of *Laphygma exigua* Huebner reared during the season of 1932, J. W. WILSON (*Fla. Ent.*, 17 (1933), No. 1, pp. 1-15, figs. 10).—The author reports from the Florida Experiment Station upon the predators and fungus parasites of the beet armyworm, which has probably been present in Florida for a number of years but because of its confusion with the southern armyworm was overlooked until the summer of 1932. It is said to be the most important lepidopterous enemy of *Asparagus plumosus* north of Auburndale.

In working on the control and biology of the beet armyworm during the summer of 1932, 8 parasites, 4 hyperparasites, and 2 predators were reared from material collected in the asparagus sheds. In addition to these parasites and predators a fungus disease was present which completely destroyed the infestation of asparagus caterpillars at certain times when the optimum weather conditions prevailed. Of the 8 parasites, *Chelonus texanus* Cress. was the most abundant and the most effective in destroying the larvae of the beet armyworm. Next in importance were *Meteorus autographae* Mues, and *Apanteles marginiventris* (Cress.) found in equal abundance. *Euplectrus platyhyponae* How. has been observed on several occasions in the ferneries at Leesburg and Pierson, but it was never abundant. At Boynton, however, it was encouraged and was very abundant.

Hyposoter disparis Viereck, an introduced ichneumonid parasite of the gipsy moth, C. F. W. MUESEBECK and D. L. PARKER (*Jour. Agr. Res. [U.S.]*, 46 (1933), No. 4, pp. 335-347, figs. 5).—The authors report upon their study of a parasite of the larva of the gipsy moth in Europe, first introduced into the United States in 1907 and first colonized in 1912. Although on rare occasions it has been shown to be a very abundant parasite of the gipsy moth in Europe, particularly in the south central part, it has not as yet become a very important control agent in New England. Its occurrence in Europe, the history of its introduction, colonization, and effectiveness are considered, followed by a description of the adult. Information on its biology and notes on the immature stages are included. The phagocytic reaction of the host as a limiting factor in this parasite's effectiveness is considered. The authors report that from 10 to more than 30 percent of the eggs and young larvae of the parasite dissected from host caterpillars that had been attacked in the laboratory and in the field were found to be dead and surrounded by phagocytes of the host.

Description of a chalcidoid parasite of *Protocalliphora* (Hymenoptera), A. B. GAHAN (*Canad. Ent.*, 65 (1933), No. 2, pp. 31-33, fig. 1).—The author erects the genus *Morodora* and describes *M. armata* n.sp., a chalcidoid parasite reared from pupae of *P. avium* Shan. and Dobr. infesting birds' nests in Montana, as reported by Jellison and Phillip (see page 382).

A revision of the Ethiopian species of the genus *Apanteles* (Hym. Bracon.), D. S. WILKINSON (*Ent. Soc. London, Trans.*, 80 (1932), pt. 2, pp.

301-344, pl. 1).—This revision of the parasites of the genus *Apanteles* includes descriptions of 8 species and 1 subspecies new to science, a host list, and keys to the species.

A hymenopterous parasite of the capsid bug *Plagiognathus arbustorum* Fab., G. L. HEY (*Ent. Mo. Mag.*, 3. ser., 19 (1933), No. 218, p. 43).—This is a note on an unidentified braconid parasite of the subfamily Euphorinae.

Five new hymenopterous parasites of the oriental fruit moth, C. F. W. MUESEBECK (*Ent. Soc. Wash. Proc.*, 35 (1933), No. 4, pp. 48-54).—Four braconid parasites of the oriental fruit moth from Japan are described as new, namely: *Bassus diversus*, *Phanerotoma grapholithae*, *Apanteles molestus*, and *Orgilus longicoeps*. A single bethylid parasite of the oriental fruit moth from New South Wales, Australia, is also described as new under the name of *Peristerola angulata*.

The birch leaf-mining sawfly, *Fenusa pumila* Klug, R. B. FRIEND (*Connecticut State Sta. Bul.* 348 (1933), pp. 289-364, figs. 24).—Following a brief historical account of this sawfly, its systematic position, and geographical distribution, the author deals at length (pp. 296-330) with its life history and habits in Connecticut, where its occurrence for the first time in this country was discovered in 1923. Its external morphology is then described, followed by control measures, a summary, and a bibliography of 35 titles. A preliminary account of this pest by the author has been noted (E.S.R., 65, p. 59).

There are three generations and sometimes a partial fourth generation in one season in Connecticut. The first adults emerge during the second week in May, and the completion of one summer generation requires about 6 weeks. Eggs are laid in the leaves of gray, white, and European white birches, only the young growing tip leaves being suitable for oviposition. The period of incubation varies from 6 to 13 days, but most of the eggs hatch in 6 to 10 days. The larva mines in the leaf from 8 to 13 days as a rule and then enters the ground to pupate. There are four feeding larval instars and a fifth instar, the prepupal stage, during which the larva is in the cocoon and does not feed.

Pupation occurs in cocoons made of particles of soil at a depth of from 1 to 2 in. below the surface of the ground. The prepupal period averages about 11 days in length in the summer, and hibernation occurs while the insect is in this stage. The pupal period is about 6 days in length. In a small proportion of cases the period in the soil (prepupal plus pupal) is prolonged in the summer to about 45 days. Beginning about the second week in August the insect begins to go into hibernation, and an increasing proportion of prepupae hibernate as the season progresses. The larvae occur in the field until the last of September and the first of October, and a few adults are found as late as the first week in October.

Natural parasitic enemies of this sawfly are not very numerous and do not appear to exert any great degree of control over its abundance, although the influence of natural factors has not been thoroughly investigated. Spraying with nicotine sulfate diluted in water at 1 part in 1,000 will kill the eggs if both sides of the leaves are covered with the insecticide. For the first generation in Connecticut, two applications should be made at weekly intervals beginning about May 25, and for the second generation three applications at weekly intervals are necessary, the first to be made about July 3.

The cholan mite (*Paratetranychus indicus*) on sorghum, M. C. CHERIAN (*Madras Agr. Jour.*, 21 (1933), No. 1, pp. 1-7, pl. 1).—This contribution reports upon observations made of the life history of *P. indicus* and measures for its control on sorghum, which next to paddy is the most important cereal crop in the Madras Presidency.

A note on the occurrence of the Australian cattle tick in Texas, H. O. SCHROEDER, JR. (*Ent. Soc. Wash. Proc.*, 35 (1933), No. 2, pp. 23, 24).—The author records the collection of *Boophilus annulatus australis* Fuller in Texas in the lower Rio Grande Valley counties of Hidalgo and Cameron. In collections made on the Mexican side of the border it was found to be restricted to an area corresponding to its occurrence on the Texas side of the river. Fully 90 percent of the cattle ticks collected at Matamoros, Mexico, were of the Australian variety. This ratio dropped to about 30 percent at Rio Rico, 30 miles farther up the river, and all those collected beyond that point were of *B. annulatus* proper.

Rocky Mountain spotted fever: Investigation of sexual transmission in the wood tick *Dermacentor andersoni*, C. B. PHILIP and R. R. PARKER (*Pub. Health Rpts. [U.S.]*, 48 (1933), No. 11, pp. 266–272).—Experiments conducted at the Rocky Mountain spotted fever laboratory, Hamilton, Mont., have demonstrated that the Rocky Mountain spotted fever virus may be transmitted from infected ticks of one sex to normal individuals of the opposite sex during copulation; also that the virus invades the tissues of the latter and is transmissible during subsequent feeding, just as would happen had the virus been acquired by ingestion or from a parent female. The experiments do not, however, explain the medium by which transfer of the virus is effected, whether by transfer of male or female secretions or by infected sperm.

Relationship between Rocky Mountain spotted fever and "exanthematic typhus of São Paulo", R. E. DYER (*Pub. Health Rpts. [U.S.]*, 48 (1933), No. 20, pp. 521, 522).—Experiments conducted in which infected ticks (*Amblyomma cajennense*) received from Brazil were fed on and also injected intraperitoneally into guinea pigs have led to the conclusion that the Brazilian disease occurring in São Paulo is identical with Rocky Mountain spotted fever. Guinea pigs immune to spotted fever are immune to the São Paulo virus.

Tick-bite fever in children, P. G. SHIPLEY (*Bul. Johns Hopkins Hosp.*, 51 (1932), No. 2, pp. 83–101, figs. 8).—An account is given dealing particularly with the disease transmitted by the American dog tick as observed in Maryland.

Ticks of the East Indian Archipelago [trans. title], B. J. KRIJGSMAN and S. A. S. PONTO (*Dept. Landb., Nijv. en Handel [Netherland East Indies], Veeartsenijk. Meded.* 79 (1932), pp. 62, pls. 5, figs. 48).—This systematic account of ticks found in the East Indies, of which 30 species are recognized, 2 being new to science, is presented in connection with a list of 32 references to the literature. The distribution of these ticks in the islands is shown by 5 insert maps.

ANIMAL PRODUCTION

Nutritive value of pasture, I–IX (*Jour. Agr. Sci. [England]*, 16 (1926), No. 2, pp. 205–274, figs. 6; 17 (1927), No. 2, pp. 209–263, figs. 2; 18 (1928), No. 2, pp. 266–296; 19 (1929), No. 2, pp. 236–265; 20 (1930), Nos. 1, pp. 53–62; 4, pp. 587–617; 21 (1931), No. 2, pp. 267–323; 22 (1932), Nos. 1, pp. 26–71, figs. 3; 4, pp. 852–873).—This series of investigations was undertaken at the Institute for the Study of Animal Nutrition, Cambridge University, to determine the chemical composition and nutritive value of the herbage of pastures.

I. Seasonal variations in the productivity, botanical and chemical composition, and nutritive value of medium pasturage on a light sandy soil, H. E. Woodman, D. L. Blunt, and J. Stewart.—In this initial paper the results are reported of investigations on the seasonal changes in productivity, botanical and chemical composition, and nutritive value of the grass from a light sandy soil of low water-retaining capacity. Grazing was imitated by the daily use of a mowing machine.

During the spring season soft chess, perennial ryegrass, annual bluegrass, and rough-stalked meadow grass made up about 80 percent of the herbage. As the season advanced soft chess and meadow foxtail disappeared almost entirely, while annual bluegrass diminished considerably. Redtop, which was entirely absent in the spring, showed great activity in the early autumn and formed the bulk of the feed at this season. Rough-stalked meadow grass, perennial ryegrass, and orchard grass persisted satisfactorily throughout the season. White clover flourished and spread under the frequent and close cuttings.

About 22 percent of the season's yield from the pasture was cut from May 11 to May 25. More bulk was produced when a hay crop and aftermath crop were cut than when plats were cut frequently. The frequent cuttings, however, showed a high percentage of protein and a low percentage of fiber as compared with the hay. There was a falling off in protein and an increase in fiber content during the dry season, followed by a recovery in both respects in late summer and early autumn.

The nutritive value of the grass was highest during the early part of the season, followed by a gradual and uniform decline during the dry season. Feeding value recovered progressively after the dry season, until in early autumn the grass was little inferior in this respect to that of the spring grass. Even at the phase of the lowest nutritive value the pasture grass was markedly superior to the best grade of meadow grass.

There was a very definite seasonal variation in the lime and phosphate content of the grass. The lime increased to the maximum in the dry mid-season and then fell off, while the phosphate content showed the opposite behavior.

II. Seasonal variations in the productivity, botanical and chemical composition, and nutritive value of pasturage on a heavy clay soil, H. E. Woodman, D. L. Blunt, and J. Stewart.—The work of the previous year was repeated on a stiff clay land and under more favorable conditions of rainfall.

During this season there was a continuous falling off in amounts of such grasses as rough-stalked meadow grass and perennial ryegrass and severe competition from creeping bent, which made up 90 percent of the mown herbage in the later stages of the season. While the frequent cuttings had a favorable effect on white clover, it did not grow as well on the clay soils. It was also thought possible that the spread of creeping bent may have decreased white clover yields.

Due to an abnormally cold, wet spring there was an absence of spring flush in growth, but in spite of this the clay pasture was more productive over the entire season than the sandy pasture. Investigations on composition and yield as compared with hay crops agreed with the results of the previous year.

The results of this test again showed that when conditions with respect to soil, herbage, and weather combined to enable the pasture to make continuous active growth, there was no serious midseason falling off in nutritive value.

The lime content of the herbage in this test was distinctly lower and the phosphorus content slightly higher than in the previous work, and the range in seasonal variation was more restricted.

The lime-phosphate ratio, while attaining a maximum during midseason, did not vary over wide limits, and at no time was seriously unsuited to the mineral requirements of adult animals.

The data concerning the utilization of the protein, lime, and phosphate constituents of the grass by sheep are presented and discussed. The ability of closely grazed pastures, when making up the entire ration, to furnish the lime and phosphate requirements of dairy cows is demonstrated.

III. *The influence of the intensity of grazing on the composition and nutritive value of pasture herbage (Part I)*, H. E. Woodman, D. B. Norman, and J. W. Bee.—The object of this phase of the study was to determine the value of cutting at 2-week instead of weekly intervals on the yield of pastures and on the composition, digestibility, and nutritive value of the herbage.

The results of the two previous experiments showed but little difference in the chemical composition, both organic and inorganic, between the two cuttings of grasses. Digestion trials showed that the dry matter of grass cut at 2-week intervals was equal in digestibility and nutritive value to that of grass cut weekly. These results indicate that pastures after being closely grazed may be permitted to make 2 weeks' unchecked growth before being grazed again without adversely affecting the value of the grass.

The light-land pasture plats under a system of 2-week cutting in 1927 produced 26 percent more dry matter, 29 percent more starch equivalent, and 21 percent more digestible protein than during 1925 when cut at weekly intervals. On the clay-land pastures the difference in productivity was partially due to weather conditions. When weather conditions were favorable to active growth of grass there was little difference in the productivity of the two systems of cutting on this type of land. However, under conditions of drought there was a markedly higher production under the system of cutting at 2-week intervals.

The significance of the results of the investigation in relation to the problem of the conservation of young grass, either dry or as silage, is discussed. A description is also presented of an outstanding case of the lowering of the palatability of pasture herbage due to the conditions of drought.

IV. *The influence of the intensity of grazing on the field, composition and nutritive value of pasture herbage (Part II)*, H. E. Woodman, D. B. Norman, and J. W. Bee.—In this phase of the study the method of cutting was refined to include 3-week intervals.

Cutting at 3-week intervals led to a slight lowering in the percentage of crude protein and a slight increase in the percentages of crude fiber and nitrogen-free extract. No corresponding effect was noted in respect to the ether extract, silica-free ash, lime, and phosphate. The depressing influence of drought on the crude protein content appeared to be more pronounced with grass cut at weekly intervals than with grass cut at 3-week intervals.

There was little difference in the digestibility of grass cut at the various intervals. The depressing effect of drought on digestibility became less pronounced as the intervals between cuttings increased. After 3 weeks' growth grass still retained the nonlignified, highly digestible character possessed by grass cut at weekly and 2-week intervals.

While the grass cut at 3-week intervals contained slightly less digestible protein, it was equal in total digestible organic matter and in starch equivalent to grass cut at shorter intervals, and the dry matter of the grass could still be considered a protein concentrate.

Under the system of cutting at 3-week intervals the herbage did not advance far in maturity and largely retained the leafiness characteristic of young grass in its vegetative and preflowering stages of growth. When plats were grazed closely at 3-week intervals pasture herbage containing a high proportion of creeping bent was not inferior from the standpoint of digestibility to other types of herbage.

The yield of dry matter over the whole season was 29.3 percent more for grass cut at 2-week intervals than for grass cut weekly, while the 3-week intervals yielded 62.3 percent more than the weekly intervals and 25.5 percent more than the 2-week intervals.

V. Pasture grass conservation: The influence of artificial drying on the digestibility of pasture herbage, H. E. Woodman, J. W. Bee, and G. Griffith.—Two investigations were undertaken to determine the influence of artificial drying on the digestibility of young leafy herbage. In the first trial grass cut at weekly intervals was dried at the temperature of steam, while in the second trial cuttings were dried by direct heat in a kiln. The digestibility of the nutrients of the grasses was determined with sheep.

The results showed that young grass does not suffer any depression in regard to digestibility when dried by either of the above methods. The high protein content and the highly digestible character of dried young grass is such that it may be used as a substitute for oil cakes for farm animals during the winter.

VI. The utilization by sheep of mineral-deficient herbage, H. E. Woodman and R. E. Evans.—The results of this study with sheep led to the belief that the failure of livestock to thrive in mineral-deficient pasture areas could not be explained by assuming that the low mineral content of the grass was responsible for a lack of palatability and a consequent depression of appetite. There was no evidence that the shortage of minerals had any depressing effect upon the digestibility of the grasses. The amount of net energy which ruminants were able to derive from any form of grass appeared to be independent of the mineral content and to depend wholly on the amount and character of the organic constituents.

Malnutrition on mineral deficient pastures was due directly to the failure of the feed to supply the necessary inorganic materials for the normal functioning of the body.

VII. The influence of the intensity of grazing on the yield, composition and nutritive value of pasture herbage (Part III), H. E. Woodman, D. B. Norman, and M. H. French.—Pasture cuttings in this phase of the study were increased to include a monthly interval.

On a dry matter basis pasture grass cut during April and May contained well over 20 percent of crude protein regardless of the interval between cuttings. During the "flush" of growth, grass cut at monthly intervals contained 18.7 percent of crude protein and 18.8 percent of crude fiber, while the grass cut at weekly intervals contained 23.7 and 16 percent, respectively, of these constituents. It was shown that during a moist, quick-drying season, characterized by greatly enhanced vegetative activity, the amount of ether extract may be depressed to a marked extent, the crude protein to a slight extent, while the crude fiber may be raised considerably. On the basis of the results of this phase of the study, it was concluded that the use of fertilizer was not attended during the first year of application by any important changes in chemical composition of the grass.

Grass cut at monthly intervals was as digestible in the early part of the season as grass cut at shorter intervals. As the season advanced, the effect of the longer interval on digestibility was determined largely by weather conditions, and where these conditions were favorable to quick growth digestibility, including that of fiber, remained as high as under more severe systems of cutting. However, during a season of drought the herbage tended to suffer some degree of lignification and its digestibility was lowered.

The dry matter of monthly-cut grass during April should be regarded as a protein-rich concentrate. During May and June under this system of cutting the nutritive ratio of the herbage widened considerably, and it was concluded that for dairy cows producing more than 5 gal. of milk daily such pastures should be supplemented with a protein concentrate. In the fall the herbage returned to its spring composition.

The monthly system of cutting, reinforced by a suitable system of fertilizing, provided the optimum conditions for the maximum yield of starch equivalent from pastures. Severe drought brought about the following changes in grass cut at monthly intervals: (1) A decided decrease in percentage of protein, (2) a slight increase in nitrogen-free extract and crude fiber, (3) a sharp increase in lime, accompanied by a decrease in phosphoric acid, (4) a pronounced decrease in moisture, and (5) a decided decline in digestibility and nutritive value.

VIII. *The influence of intensive fertilizing on the yield and composition of good permanent pasture (seasons 1 and 2)*, H. E. Woodman and E. J. Underwood.—This phase of the study was designed to determine the effect of periodic applications of sulfate of ammonia on the yield and composition of good permanent pasture, well supplied with reserves of lime, potash, and phosphate.

During the first year of application of sulfate of ammonia there was a slight increase in the crude protein content of the herbage, the most marked effect occurring in April and October. During the second year this improvement was not manifested. This fertilizer had no significant effect on the fiber content of the grasses. The sulfate of ammonia had a slightly depressing effect on the lime content, which was more marked in the second season, had no effect on phosphate, and enabled the herbage to maintain a high level of potash during the drought season. During the first season the fertilizer brought about a small increase in the percentage of chlorine, but had no such influence during the second season. No significant effect on the soda content of the herbage was noted.

Over a 2-year period the plats receiving sulfate of ammonia yielded 49.6 lb. more nitrogen per acre than the plats receiving the basal treatment only. The outstanding effect of sulfate of ammonia was the production of an essentially grassy type of herbage and the marked discouragement of weeds.

IX. *The influence of the intensity of grazing on the yield, composition and nutritive value of pasture herbage (Part IV)*, H. E. Woodman and D. B. Norman.—In this phase of the study the interval between successive cuts was lengthened to 5 weeks to determine the consequences of adopting in actual practice a 5-week rotational close-grazing system.

This method of cutting led to a definite, though not serious, reduction in the digestibility of the herbage, which was most noticeable during the flush period of growth. The constituent most affected was the crude protein. During a season of favorable rainfall this method of cutting prevented the herbage from becoming lignified and of greatly reduced digestibility, but during a season of drought there was a possibility of premature lignification where this system was followed. During April the herbage had a protein-concentrate nature similar to herbage mowed at shorter intervals, but during the flush period of growth there was a considerable drop in respect to the digestible protein. Beginning in July the digestible protein content began to increase again. A review of these results showed that during the quick-growing season pasture grass under a 5-week rotational close-grazing system had a slightly lower feeding value than grass grazed down at monthly intervals, but that as the season progressed the nutritive value of the two systems of grazing tended to become equal.

The dry matter of the herbage mowed at 5-week intervals contained on the average over the entire season 63.9 percent of starch equivalent, including 12.6 percent of digestible protein. Such grass, even in periods of lowest mineral content, had sufficient lime and phosphate to meet the requirements of dairy cattle.

The American Society of Animal Production: Record of proceedings of the twenty-fifth annual meeting, November 25–26, 1932 (*Amer. Soc.*

Anim. Prod. Proc. 1932, pp. 412, figs. 18).—This is the report of the annual meeting held at Chicago, November 25 and 26, 1932 (E.S.R., 68, p. 227). The following papers were presented in the cattle, horse, swine, sheep and wool, nutrition, and meats sections:

Public Aid for Livestock Breeders, by J. A. Hill (pp. 9-14); The Use of Statistical Methods in Animal Husbandry, by J. L. Lush (pp. 15-19); The Use of Simple Statistical Methods in Nutrition Investigations, by L. A. Maynard and C. M. McCay (pp. 20-24); An Improved Design for Experiments with Groups of Animals Whose Outcome May be Estimated, by G. W. Snedecor and C. C. Culbertson (pp. 25-28); Results of Tests of Illinois Farm Scales, by R. C. Ashby (pp. 29-31); Net Energy of Completely Balanced Nutrient as a Measure of Nutritive Value of Rations and of Nutritive Requirements of Animals, by E. B. Forbes (pp. 32-40); Evaluating Beef Cattle Performance for a Register of Merit, by E. W. Sheets (pp. 41-47); Livestock Records of Performance and Their Value to the Meat Industry, by E. N. Wentworth (pp. 48-51); Show Ring Winnings as a Means of Evaluating Sires, by J. C. Holbert (pp. 52-55); Fattening Cattle of Different Market Grades, by W. H. Peters (pp. 56-59); Ground Limestone for Fattening Cattle, by C. W. McCampbell (pp. 60-62); Baby Beef and What It Means to the Laity, by E. S. Good (pp. 63, 64); Tankage in the Fattening Cattle Ration, by P. Gerlaugh (pp. 65-67); Machine Dried versus Field Cured Soybean Hay for Beef Steers, by M. G. Snell (pp. 67-69); Studies on Producing Lower Cost Silage, by F. R. Edwards (pp. 70, 71); Minerals for Range Cattle, by J. L. Lantow (pp. 71, 72); Value of a Brahman Cross on Native and Grade Beef Cattle in Southern Louisiana, by C. I. Bray (pp. 72-76); A Comparison of Body Measurements of Beef and Dual Purpose Cattle, by B. Knapp, Jr., and A. C. Cook (pp. 77-84); The Relation of Dietary Fat and Fat Derivatives in the Feces of Dairy Calves, by C. Y. Cannon, D. L. Espe, and J. B. Walde, Jr. (pp. 85-90); The Chemical Composition of Early Pasture Legumes and Grasses, by R. H. Lush (pp. 91-94); Seasonal Variation in Composition and Digestibility of Certain Species of Range Bunch Grasses, by R. McCall (pp. 95-100); Cottonseed Products for Fattening Calves, by W. L. Blizzard (p. 101); The Use of Oat Feed as the Entire Ration for Horses at Light to Medium Work, by A. W. Lathrop and G. Bohstedt (pp. 102-104); Strongyle Infestation in Horses, by R. Graham (pp. 105-109); Blackstrap Molasses as a Feed for Louisiana Work Mules, by M. G. Snell and W. G. Taggart (pp. 110-112); Feeding Draft Colts, by R. S. Hudson (pp. 113-115); What Type of Horses Should the Corn Belt Farmers Produce and Use? by J. L. Edmonds (p. 115); Equipment Employed in Studying the Calcium, Phosphorus, and Nitrogen Metabolism of Draft Horses, by B. H. Thomas and A. L. Harvey (p. 115); Horse Extension Activities in the Buckeye State, by L. P. McCann (pp. 116-118); Demonstrating Big-Team Outfits, by E. T. Robbins (pp. 118-122); A National View of Extension Work in Horse Husbandry, by W. Dinsmore (pp. 123-126); The Nutritive Value of Soybeans with Preliminary Observations on the Quality of Pork Produced, by C. M. Vestal and C. L. Shrewsbury (pp. 127-130); Wheat and Soybeans as a Feed for Swine, by A. E. Tomhave (pp. 131-133); Production Tests for Selection of Breeding Hogs, by E. F. Ferrin (pp. 134-137); The Optimum Degree of Fineness of Grinding Corn for Growing and Fattening Swine, by M. A. McCarty and J. E. Nicholas (pp. 138-140); Anemia in Suckling Pigs, by J. P. Willman, C. M. McCay, and F. B. Morrison (pp. 141-145); Preliminary Results from Grinding Barley and Wheat for Pigs, by V. A. Freeman (pp. 146, 147); Fattening Pigs on Small Grains, by T. Wright (pp. 148-150); The Use of Slacked Coal and Charcoal in Swine Feeding, by C. P. Thompson (p. 150); Sodium Bicarbonate at Different Levels for Growing Gilts on Pasture, by A. L. Anderson, C. C.

Culbertson, J. M. Evvard, and W. E. Hammond (pp. 151-154); Dried Caplin Fish Compared with Tankage as a Protein Supplement for Swine, by W. C. Skelley (pp. 155, 156); Value of Permanent Pasture for Fattening Pigs, by E. H. Hostetler (pp. 157, 158); A Comparison of Some Southern Protein Supplements for Fattening Swine, by Z. A. Massey (pp. 158, 159); Sweet Potatoes for Swine, by C. I. Bray (pp. 160-164); Rice Polish for Growing and Fattening Swine, by E. Martin (pp. 164-169); Some Observations on Pigs Receiving Vitamin A Deficient Rations, by J. H. Longwell and C. E. Weakley, Jr. (pp. 169-173); The Influence of Nutrition on the Oestrous Cycle in the Ewe, by A. E. Darlow and L. E. Hawkins (pp. 173-176); Experiments with Timothy Hay for Pregnant and Nursing Ewes, by D. S. Bell, L. E. Thatcher, and C. H. Hunt (pp. 176-180); The Effect of Early Breeding on Ewes, by D. J. Griswold (pp. 181-183); Making Sweet Clover Pastures Available Earlier in the Spring, by C. W. Hickman and J. E. Nordby (pp. 184, 185); Safe and Economical Ways of Self-feeding Lambs, by G. Bohstedt (pp. 185-187); The Need of New Units of Measurement in Wool Research, by J. F. Wilson (pp. 187-189); Market Grades of Lambs, by W. A. Netsch (p. 189); Lamb Feeding Investigations at Washington State, by H. Hackedorn (pp. 190-192); A Move toward Registry of Merit for Rambouillet Sheep, by D. A. Spencer (pp. 193-197); Discussion, by F. S. Hultz (pp. 198-200); Biological Values of the Proteins, Digestion Coefficients of Organic Nutrients, and Calcium and Phosphorus Balances of Lamb Rations Consisting of Alfalfa Leaves and Stems, by J. Sotola (pp. 200-204); The Efficacy of Copper in the Regeneration of Hemoglobin in Anemic Lambs, by B. H. Thomas and S. S. Wheeler (pp. 204-208); Function of Minerals in Nutrition, by R. B. Becker (pp. 201-207); Under What Conditions Are Calcium and Phosphorus Supplements Needed in the Feeding of Farm Animals, by G. Bohstedt (pp. 208-302); The Value of Different Calcium Supplements in Animal Feeding, by L. A. Maynard (pp. 303-308); The Effect of Vitamin D and Irradiation on the Utilization of Calcium and Phosphorus, by R. M. Bethke (pp. 309-316); Under What Conditions Are Mineral Supplements Other Than Salts of Calcium and Phosphorus Necessary in Feeding Farm Animals, by T. S. Hamilton (pp. 317-343); The Nutritive Requirements of the Dairy Cow Expressed in Accord with a New Method of Application of the Net-Energy Conception: A Correction, by E. B. Forbes and M. Kriss (pp. 344, 345); A Practical Method of Measuring Color in Beef, by D. L. Mackintosh (pp. 345-353); Differences between Barrows and Gilts in the Proportion of Pork Cuts, by M. D. Lucy (pp. 354-357); Some Relationships among Factors in the Production and Grade of Beef, by O. G. Hankins and L. B. Burk (pp. 358-364); Meat Production, Distribution, and Consumption, by W. W. Woods (p. 364); and Influence of Cooking and Canning on the Vitamin B Content of Beef and Pork, by F. W. Christensen, E. Latzke, and T. H. Hopper (pp. 365-368).

[Animal husbandry experiments at the New Hampshire Station] (*New Hampshire Sta. Bul. 270 (1933), pp. 5, 6, 19-21*).—Data are reported from a comparison made by E. G. Ritzman and F. G. Benedict of the nutritive value and digestibility of timothy hay cut before bloom, during early bloom, and after the formation of seed; studies by Ritzman of metabolism in the horse and the basal energy requirements of two Berkshire sows; and studies by A. E. Tepper, T. B. Charles, and F. D. Reed on the use of high protein rations in battery brooding of chicks, the value of soybean meal for chick feeding, yellow corn meal and alfalfa meal as sources of vitamin A, and the effect of high battery brooding temperatures.

[Experiments in animal production at the Union Substation] (*Oregon Sta., Oregon Livestock Branch Sta. [Pamphlet, 1933], pp. 3-6, figs. 2*).—Brief

reports are given of the results of experiments conducted on wintering beef cows on straw and alfalfa hay, the feeding of baby beeves on cut and long alfalfa hay with barley and wheat rations, the shrinkage of baby beef calves shipped from Union to Portland, the influence of exercise on ewes, and winter rations including alfalfa hay for brood sows.

Growth and development with special reference to domestic animals.—XXVI, The energy increment of standing over lying and the cost of getting up and lying down in growing ruminants (cattle and sheep); comparison of pulse rate, respiration rate, tidal air, and minute volume of pulmonary ventilation during lying and standing, W. C. HALL and S. BRODY (*Missouri Sta. Res. Bul.* 180 (1933), pp. 31, figs. 4).—Continuing this series of studies (E.S.R., 69, p. 94), data are presented on the energy metabolism, as determined by the closed-circuit oxygen-consumption method previously described (E.S.R., 63, p. 760), of Guernsey, Jersey, Holstein, and Hereford cows, a Hereford steer, Holstein and Hereford heifer calves, and Dorset ewes. The tests were conducted on trained animals. The percentage energy increment for standing as compared with lying was calculated at about 9 percent for dairy cattle and Dorset sheep, 7 percent for a Hereford cow, and 13 percent for a fat Hereford steer. In addition to the averages of 1,989 measurements of the energy metabolism of these animals, the data are presented to show the heat measurements by weight and surface area and pulse rate, respiration rate, tidal air, and pulmonary ventilation during lying and standing. Both the rate and amount of air breathed in and out of a unit of time and per respiration and pulse rate were found to vary with the condition of the animal as to lying, standing, getting up, or lying down, fasting, etc. Statistical constants are presented for the measurements on each group of animals.

The periods of embryonic growth in cattle, D. A. KISLOVSKY and B. A. LARCHIN (*Jour. Agr. Sci. [England]*, 21 (1931), No. 4, pp. 659-668, figs. 3).—A study was made of 15 calf embryos ranging in age from 40 to 270 days by the Department of Animal Breeding, Institute of Dairy Farming, U.S.S.R. The embryos were obtained from Domshino cattle and were weighed and measured immediately after the cows were slaughtered.

The preliminary results in this study demonstrated that there are, beginning 40 days after conception, five periods of growth in the calf during the self-accelerating phase of growth. The periods differ in length in various breeds. Some breeds, such as the highly developed dairy breeds, pass the last break in rate of growth before birth, while other breeds sometimes have as many as two such breaks after birth.

The effect on the foetus and milk and beef production of the removal and transplantation of the ovaries of large mammals, M. MANRESA (*Univ. Philippines, Nat. and Appl. Sci. Bul.*, 2 (1932), No. 2-3, pp. 149-161, fig. 1).—The results of a study at the College of Agriculture, University of the Philippines, showed that the complete removal of the ovaries from pregnant cattle was followed by abortion. Ovariectomy prolonged the period of laceration and caused a marked increase in the total amount of milk produced. It was not determined whether the operation increased the rate of milk flow.

Spayed females lost their feminine appearance and approached castrated males in disposition and in general physical condition. The body weight, dressing percentage, and quality of beef of female cattle were favorably affected by spaying. It was concluded that for cattle and carabaos spaying offered a practical means for the elimination of old and inferior animals.

Wheat as a fattening feed for cattle, A. D. WEBER and W. E. CONNELL (*Kansas Sta. Bul.* 261 (1932), pp. 20).—Following the presentation of a sum-

mary of experiments in which wheat was fed to cattle, the results of two series of experiments are reported in which wheat was compared with shelled corn for finishing 80 yearling steers in a 180-day test. There were four lots in each series, averaging from 604 to 620 lb. in live weight. All received cottonseed meal and alfalfa hay, and sorghum silage also was fed in the first series. In addition to these feeds lot 1 received ground shelled corn; lot 2, a mixture of ground shelled corn and ground wheat 2:1; lot 3, ground shelled corn and ground wheat 1:2; and lot 4, ground wheat.

The results showed that all lots made average daily gains of more than 2.2 lb. Wheat was thus a very efficient producer of gains, but it was less palatable than ground corn when fed alone. The mixtures of wheat and corn proved equivalent to corn alone. The carcasses of the steers fed wheat as the sole grain did not grade as high as those receiving corn alone, but those receiving corn and wheat 1:2 produced carcasses equal to the steers fed on corn as the sole grain ration.

A note on Wood and Capstick's method of calculating the maintenance requirements of the adult sheep, W. A. HENDRICKS and H. W. TITUS (*Jour. Agr. Sci. [England]*, 21 (1931), No. 4, pp. 726-738, figs. 2).—In the course of studies relating to the maintenance requirements of chicks at the U.S.D.A. Animal Husbandry Experiment Farm, Beltsville, Md., the authors became interested in and made a study of the maintenance requirement of adult sheep as calculated by Wood and Capstick (*E.S.R.*, 57, p. 68).

The analysis of Wood and Capstick's data showed that when the range in live weight of the experimental animals is small there is little justification for attempting to refine the calculations by assuming proportionality between the maintenance requirement and the two-thirds power of the live weight of the animal. While the maintenance requirement of an animal is affected by its surface area, small differences may be obscured by the effects of other factors contributing maintenance requirement.

It is believed that the level of feed intake as well as the size and activity of the animal influence to some extent the maintenance requirement. When the range in live weight of experimental animals is small, the effects of all factors contributing to maintenance may be such that the higher maintenance requirements tend to be associated with the lower live weights. It is also considered possible that the lack of proportionality between maintenance requirement and the two-thirds power of the live weight was due to the fact that the surface area is, in some cases, not proportional to the two-thirds power of the live weight. When animals are not uniform in condition, heavier animals need not have a correspondingly greater surface area than lighter animals. The chemical composition of gains and losses in live weight largely determine the amount of feed to which they are equivalent, and these chemical changes in live weight are dependent to some extent upon the condition of the animal.

The care, feeding, and management of sheep, P. S. SHEARER (*Iowa Sta. Circ.* 138 (1932), pp. 31, figs. 18).—A popular account of the sheep industry in Iowa, including discussions of breeds, methods of feeding, breeding, and management of sheep, and control of common diseases and parasites.

Sheep feeding, W. C. SKELLEY (*New Jersey Sta. Circ.* 277 (1933), pp. 4).—A brief discussion of feeds and suggested rations for sheep.

Hogging-off corn and sweet potatoes and feeding cull sweet potatoes to hogs, C. I. BRAY and J. B. FRANCONI, JR. (*Louisiana Sta. Bul.* 236 (1933), pp. 39, figs. 4).—In two experiments hogging-off corn and soybeans was compared with dry lot feeding of corn. Supplements of shrimp meal, cottonseed meal, and rice polish in one case and alfalfa hay as a substitute for the rice polish in

the other were provided. The pigs fed the first year for 45 days made average daily gains of 1.2 lb., but in the second experiment hogging-off corn and soybeans produced average daily gains in a 33-day test of 1.5 lb. as compared with 1.4 lb., the average daily gains produced by hogs fed in dry lot. Good returns were calculated for the corn and soybeans hogged off.

The results of six experiments conducted over a period of 5 years, in which sweetpotatoes were compared with corn in field tests and in the dry lot, where more accurate determinations of the feed consumption could be made, are briefly reported. The combined results demonstrate the importance of adding a protein concentrate to the sweetpotato rations, although soybeans hogged off and sweetpotato vines had important supplemental value. The number of pounds of sweetpotatoes equivalent to 1 lb. of concentrates was calculated under the following feeding conditions: As sweetpotatoes fed alone, 10.4; when fed with a protein supplement in dry lot, 7.7; when hogged off in the field and additional protein supplements provided, 4.9; and when fed with corn and protein supplement in dry lot, 4.3 lb. Thus about 30 bu. of sweetpotatoes fed with a protein supplement were required per 100 lb. of gain.

The influence of maize germ on the quality of bacon, C. CROWTHER (*Jour. Min. Agr. [Gt. Brit.], 39 (1932), No. 5, pp. 428-440*).—A series of tests was undertaken at the Animal Nutrition Research Institute, Cambridge, the Harper Adams Pig Feeding Experimental Station, and the Chemical Research Division of the Ministry of Agriculture for Northern Ireland to determine the value of degermed maize for feeding to bacon hogs. The feeding scheme consisted of four lots of pigs fed either flaked yellow maize (including germ), flaked yellow maize (degermed), raw yellow maize meal (including germ), or flaked white maize (degermed). However, it was possible at only one of the stations to provide all the lots.

The results as a whole showed that degermed maize produced a better quality of bacon than ordinary maize meal containing the germ. That the nutritive value of the maize was not impaired by the removal of the germ was shown by the comparable gains in live weight in all the lots. The relatively small differences in the quality of the bacon suggested that the importance of the food-oil factor in determining quality has been exaggerated. The results also suggested that the changes brought about in the maize by cooking, as in the preparation of flaked maize, may have a separate influence upon quality, as may also inherited characteristics of the pigs themselves.

The composition of mare's milk, R. G. LINTON (*Jour. Agr. Sci. [England], 21 (1931), No. 4, pp. 669-688*).—Samples of milk from 142 mares were analyzed at the Royal Veterinary College, Edinburgh, to determine the content of solids, protein, fat, lactose, and ash as compared with previously reported analyses. Of the total samples, 38 were taken during the period of colostrum secretion.

The average ash content of the milk of British mares was 0.51 percent as compared with an average of 0.38 percent for continental mares. With the lighter British breeds the ash content was similar to that of continental mares. There were no other marked differences in the composition of the milk of British and continental mares.

Analyses of the milk from mares whose foals were not thriving showed the milk to be abnormal in practically all cases. The occurrence of oestrus commonly caused nutritional disturbances in the suckling foal. Milk with a high percentage of fat was unsuitable for foals, and they appeared to thrive well when the milk contained very little fat. The lactose of mare's milk was fairly constant and a slight excess did not appear to be harmful, but foals did not thrive well when the milk contained much less lactose than the normal amount. Aged mares either secreted milk of normal composition or milk with

a tendency toward richness. The colostrum of mares had the same characteristics as that of cows.

[Poultry experiments at the Maine Station] (*Maine Sta. Bul. 363 (1932), pp. 247-250, figs. 2*).—The results of studies are reported by W. F. Dove dealing with the influence of different methods of drying on the vitamin D and protein value of dried Maine sardines and whitefish and with the influence of red light on the action of antirachitic substances in poultry rations.

Experimental errors in chicken-raising experiments, R. W. HALE (*Jour. Agr. Sci. [England], 21 (1931), No. 4, pp. 716-725, fig. 1*).—Experiments designed to compare different rations and methods of management as regards their effect on the rate of growth of chickens and on the subsequent laying power and weight of the pullets were conducted at the Agricultural Research Institute of Northern Ireland. The study covered two seasons and involved 45 groups of from 30 to 100 chicks each.

It was concluded that the weights of cockerels and pullets should not show a standard deviation much greater than 15 percent of the mean weight for the group, unless the experimental treatment or other conditions have seriously interfered with the rate of growth. A comparison of mean weights and of standard deviations may be misleading unless cockerels and pullets are considered separately.

The author has tabulated the smallest significant differences between the mean weights of groups for standard deviations of 15, 17.5, and 20 percent and for groups of from 10 to 100 birds.

The efficiency of New Orleans sunshine in preventing leg weakness and promoting growth in chicks, H. S. MAYERSON and H. LAURENS (*Poultry Sci., 11 (1932) No. 6, pp. 325-334*).—A study was undertaken with 2-day-old chicks to determine whether the antirachitic wave lengths of sunlight would be absorbed or diminished in their passage through the atmosphere at the low elevation and under the semitropical conditions of New Orleans. In addition to exposing chicks to direct sunshine and skyshine (reflected radiation from sky and clouds), other groups were kept under Vitaglass, Corex D, and Cel-O-Glass. The same basal ration was fed to all lots. The positive control lot received 2 percent of cod-liver oil in addition, while the negative control lot received the basal ration only. Each test was conducted for 6 weeks, and the chicks were weighed weekly. At 8 weeks of age the chicks were X-rayed, killed, and the blood pooled for the determination of serum calcium and phosphorus.

Observations covering a period of 27 months showed that average daily exposures of about 2 minutes to sunshine during July, August, and September; of between 2 and 3 minutes during April, May, June, and October; of 5 minutes during November, December, and January; and of from 3 to 5 minutes during February and March prevented the appearance of leg weakness and promoted normal growth in chicks on vitamin D deficient diet. With skyshine average daily exposures of from 6 to 11.4 minutes from July through October; of 35 minutes from November through February; and of from 18 to 19 minutes from March through June were necessary for normal calcification and growth. Chicks exposed under Vitaglass, Corex D, and Cel-O-Glass to sunshine were protected from rickets throughout the year by exposures correspondingly greater in proportion to the relative absorption of these materials.

The minimum amount of solar energy of wave lengths shorter than 313 m μ , effective in preventing leg weakness, was found to be approximately 0.00069 g calories per square centimeter (48.3 μ w) daily. Measurement of the additional skyshine to which chicks were exposed showed that a total radiation of wave lengths shorter than 313 m μ from sun to sky equivalent to approximately

0.00134 g calories per square centimeter (99.8 μ w) daily produced proper calcification and growth.

Salt tolerance of baby chicks, G. D. QUIGLEY and R. H. WAITE (*Maryland Sta. Bul.* 340 (1932), pp. 343-370, figs. 18).—In a test of the effect of different amounts of salt in the ration of chicks, six lots of 14 chicks each were fed mash rations containing 1, 3, 5, 8, 10, and 15 percent of salt, respectively. Up to 9 weeks of age mortality was not excessive until the level of salt in the ration was 8 percent or above. The rations containing the larger amounts of salt were unpalatable and interfered with growth because of reduced feed consumption, but caused no permanent injury. Large amounts of water were consumed, and the feces were watery when excessive amounts of salt were included in the ration.

Studies of the tolerance of other groups of 90 chicks to large single doses showed that the minimum lethal dose was about 4 g of salt per kilogram of live weight. A somewhat larger total dose was tolerated if it was divided and administered at 4-hour intervals.

Chicks dying from salt poisoning showed a large hemorrhage at the base of the heart, severe bloody congestion of the kidneys, and a more or less slimy appearance of the lining of the proventriculus, gizzard, and intestine. Histological examination of various tissues of the birds, by E. Bray, showed no striking abnormalities, but difficulty was encountered in fixing and sectioning the kidney tissue of the affected birds.

Curved-line relationships between certain short-period egg yields and annual egg production in Single-Comb White Leghorn fowls, W. C. THOMPSON (*Jour. Agr. Res. [U.S.]*, 46 (1933), No. 4, pp. 349-359, figs. 3).—Based on a study at the New Jersey Experiment Stations of the egg production records of 3,937 birds in three egg-laying contests conducted over a period of two years, relationships were calculated between the total annual egg production, the winter egg production during the period October 1 to January 28, the late-summer egg production during the 30 days August 25 to September 23, and the winter plus the late-summer production.

The linear correlations calculated between total annual production and winter yields were 0.6352 ± 0.0064 and total annual production and winter plus late-summer egg production 0.6711 ± 0.0088 . The curvilinear correlations between these variables were, respectively, 0.6641 ± 0.0033 and 0.7150 ± 0.0078 . The linear regression equations calculated between annual and winter egg production were $Y \text{ (annual)} = 1.553 X \text{ (winter)} + 115.032 \pm 30.8435$ and annual egg production with winter plus late-summer production $Y \text{ (annual)} = 0.8138 X \text{ (winter plus late-summer)} + 153.2667 \pm 28.4184$. Partial correlations between total and winter egg production with later-summer production held constant were also calculated. On account of the curvilinear relationship existing between the variables as determined by the Blakeman test, a slight improvement in the prediction value was obtained by use of a logarithmic regression equation.

Poultry breeding, M. A. JULL (*New York: John Wiley & Sons; London: Chapman & Hall*, 1932, pp. XIV+376, figs. 71).—Breeding practices that should be followed in order to increase the average production of the poultry flock are discussed. The fundamental principles of inheritance are explained so that the breeder may have a clearer understanding of the method in which characters of economic importance are transmitted from parent to offspring. The value of progeny testing as a means of determining progress is also explained.

Turkey growing trials (*Oregon Sta., Umatilla Branch Sta. [Pamphlet, 1933], p. [6], fig. 1*).—A comparison was made of the supplemental value of green feeds and protein mash for growing turkeys.

DAIRY FARMING—DAIRYING

Proceedings of the 27th annual meeting of the American Dairy Science Association (*Jour. Dairy Sci., 15 (1932), No. 6, pp. 489-497*).—A brief résumé of the meeting held at the University of Kentucky from June 28 to 30, 1932, together with the titles of papers presented in the various sections of the association (*E.S.R., 67, p. 165*).

A study of the effects of alfalfa hay and irrigated pasture on growth of Holstein heifers, H. S. WILLARD (*Jour. Dairy Sci., 15 (1932), No. 6, pp. 435-444, figs. 2*).—In a study at the Wyoming Experiment Station 20 Holstein heifers, varying in age from 6 to 24 months, were divided into two lots. During the winter lot 1 received alfalfa hay as the only feed, while lot 2 received alfalfa hay plus 2 lb. of ground barley per head daily. In summer both lots were run on irrigated sweetclover and tame grass pasture without additional feed.

During the winter months lot 1 made average monthly gains of 28.5 lb. while lot 2 gained 32 lb. The older heifers made larger gains in lot 1 than the younger heifers. The average monthly gains for all heifers in both lots while on pasture was 40.6 lb. While the heifers that received grain during the winter made somewhat larger gains on pasture than those that had received alfalfa alone, little significance was attached to this fact because of the limited number of animals and also because lot 1 made very satisfactory gains during the winter. The two groups were about the same size at 27 months.

The successful growth of heifers raised without grain in this test was attributed to two facts: (1) That the animals were of sufficient size at 12 months of age to consume enough roughage for desirable growth, and (2) the possible beneficial effect of irrigated pasture.

The control of pastures on some farms in Finland (Suomi) in the summer of 1931 [trans. title], C. A. G. CHÄRPENTIER ([*Finland*] *Valtion Maatalouskoetointinnän Julkaisu. No. 49 (1932), pp. 104, Swed. and Eng. abs., pp. 75-84*).—Continuing these studies (*E.S.R., 68, p. 84*), the yield on the forest pastures increased somewhat in comparison with the previous year. The yield on cultivated pastures on wooded lands was somewhat smaller, while the yield on arable land pastures decreased 200 fodder units per hectare as compared with the previous year. On the arable land pastures there was an average production of 1,787 kg of milk and an average increase in weight of 65 kg per hectare.

Spring-calving cows gained from 8 to 467 g per day, autumn-calving cows 54 to 453 g, winter-calving cows 42 to 456 g, pregnant heifers 189 to 671 g, and 1- to 2-year-old heifers from 324 to 584 g per head daily. The spring-calving cows produced from 6.5 to 18.8 kg of milk, autumn-calving cows 2.3 to 11 kg, and winter-calving cows from 5.5 to 12.5 kg of milk per day. The fodder consumption in fodder units per head per day was for spring-calving cows from 4.9 to 11.4, autumn-calving cows 3 to 9.4, winter-calving cows 3.8 to 9.7, pregnant heifers 2.7 to 5, 1- to 2-year-old heifers 2.2 to 5, and calves 2.2 to 3.4. The cost per fodder unit of pasture was somewhat lower in 1931 than in the previous year, due to the lower fertilizer costs.

Vitamin A content of pasture plants.—I, White clover (*Trifolium repens*) and Kentucky blue grass (*Poa pratensis*) under pasturage conditions and fed green, E. WOODS, A. O. SHAW, F. W. ATKESON, and R. F. JOHNSON (*Jour. Dairy Sci., 15 (1932), No. 6, pp. 475-479, fig. 1*).—In a prelim-

inary study at the Idaho Experiment Station the technic of Sherman and Monseil (*E.S.R.*, 54, p. 89) was used for determining the vitamin A content of some pasture plants. After the experimental rats used had been depleted of vitamin A, each of the above plants was fed at levels of 60, 180, and 600 mg per week.

The results indicated that white clover contained at least 200 units of vitamin A, and that bluegrass had about 100 units. On the basis of these results, white clover is one of the best sources of vitamin A and bluegrass ranks with the best dried alfalfa.

Sudan grass as hay, silage, and pasture for dairy cattle, J. R. DAWSON, R. R. GRAVES, and A. G. VAN HORN (*U.S. Dept. Agr., Tech. Bul. 352 (1933)*, pp. 28, figs. 2).—Data are presented on the yields and feeding value for dairy cattle of Sudan grass as hay, silage, and pasture in studies conducted at the Woodward, Okla., Dairy Experiment Station from 1928 to 1931. The average yields of air-dry hay per acre when cut at different stages of growth were 4,033 lb. for hay cut when first heading, 3,925 lb. when fully headed, and 3,922 lb. when cut in the soft-dough stage. The yields obtained from cuttings at 30-day intervals were largely dependent upon the distribution of the rainfall over the season.

The chemical composition of the hay was closely correlated with the maturity of the plant and the rainfall. The percentage of protein and fat was depressed and the nitrogen-free extract increased as the days of growth increased. The yield of crude protein per acre was greatest in the early-cut Sudan. In 2 years' feeding tests the hay cut when first heading was most palatable. The hay and Sudan silage gave satisfactory milk production and maintained milk yields in a relatively good manner. Sudan was also a very good pasture crop for cattle, but 33 percent more nutrients were produced per acre from Sudan grass hay when first heading than from Sudan pasture.

The economy of conversion of food energy into milk energy by the dairy cow, E. B. FORBES and L. VORIS (*Jour. Nutrition*, 5 (1932), No. 4, pp. 395-401).—At the Pennsylvania Institute of Animal Nutrition it was found that nine Holstein cows with an average live weight of 520.8 kg (1,146 lb.) and an average milk production for one lactation period of 5,356 kg, transformed approximately 21 percent of their feed energy into milk energy during the period of 313 days. The most efficient cow converted 23.4 percent and the least efficient cow 18 percent of the feed energy into milk energy during this period.

The hemoglobin content of the blood of healthy and anemic "salt-sick" cattle, W. M. NEAL and R. B. BECKER (*Jour. Agr. Res. [U.S.]*, 46 (1933), No. 6, pp. 557-563).—Determinations at 2.5-hour intervals of the hemoglobin by the Newcomer acid-hematin method of blood samples of 10 normal Jersey heifers and dry cows at the Florida Experiment Station averaged 13.27 g of hemoglobin per 100 cc with a standard deviation of ± 0.162 g. Considerable individual variation was evident in animals bled on successive days and at different intervals. There was evidence, however, that the concentrations of hemoglobin were higher and more regular in blood samples drawn during the early afternoon and early forenoon. Hemoglobin determinations on cattle from 39 herds exhibiting more or less nutritional anemia showed that the hemoglobin content of the blood of anemic animals was considerably lower than in normal animals. In 87 head visibly affected the average was 8.28 g of hemoglobin per 100 cc of blood. The lowest value observed was 1.37 g in a calf shortly prior to death. An animal exhibiting anemia which recovered on supplements of iron and copper showed the presence of 3.02 g of hemoglobin per 100 cc of blood. Others ranging above this amount showed recovery when the iron and copper supplements were fed.

Plasma phosphatase in dairy cows suffering from fluorosis, P. H. PHILLIPS (*Science*, 76 (1932), No. 1967, pp. 239, 240).—Because it seemed possible that a change in plasma phosphatase might be a means of detecting chronic fluorine poisoning, six lots of three heifers were fed rations balanced as to protein and containing ample energy at the Wisconsin Experiment Station. Three of the lots received no known source of fluorine, while the other lots received approximately 0.02, 0.04, and 0.087 percent of the grain ration as fluorine fed as a mineral supplement in the form of raw rock phosphate. Blood samples were taken during the first lactation as follows: (1) Prior to parturition, (2) near the peak of production, (3) mid-lactation or later, and (4) near the end of lactation.

There was a definite gradation in the plasma phosphatase between lots and a progressive rise in plasma phosphatase in the high-fluorine lot accompanying the progressive severity of the poisoning as expressed in the gross symptoms of the animals. These changes were in all likelihood due to the increased grain required to meet the needs of lactation and the subsequent higher fluorine intake. The plasma phosphatase values in the high fluorine lots at the respective stages were 0.2787, 0.3142, 0.3537, and 0.4227 units per cubic centimeter. It was concluded that in the absence of other bone diseases plasma phosphatase in fluorosis is a sensitive test for the toxic effects of chronic fluorine poisoning.

The heat production of cattle in a respiration calorimeter as related to the rate of ventilation and to the moisture content of the air, E. B. FORBES, W. W. BRAMAN, and M. KRISS (*Jour. Nutrition*, 5 (1932), No. 4, pp. 387-394).—The heat production of a dry cow, on a constant ration, was measured in a respiration calorimeter at the Pennsylvania Institute of Animal Nutrition by both direct and indirect calorimetry in eight consecutive 24-hour observation intervals to determine the effects of the rate of ventilation on the paths of outgo of heat from the animal and on total heat production. The rate of ventilation was rapid or slow in alternate 24-hour periods. The rapid rate was about 35,000 l per hour and the slow rate from 5,414 to 5,454 l per hour. During the last half of the observation periods approximately 85 percent of the moisture was removed from the ingoing air by freezing.

The outcoming air contained 10.3 times as much carbon dioxide at the slow rate of ventilation and 1.8 times as much at the high rate of ventilation as that permitted by the King standard for barn ventilation (E.S.R., 20, p. 887). The moisture content of the outcoming air was 1.4 times as great at the slow rate of ventilation as at the rapid rate.

With both methods of determining heat production there was a slight decrease in the amount of heat with each change in ventilation from rapid to slow and a slight increase in the heat produced with a change from slow to rapid. About 40 percent of the heat produced was eliminated as the latent heat of water vapor, the quantity generally decreasing to some extent with a decrease in rate of ventilation.

The authors conclude that since the carbon dioxide content of the outcoming air at the slow rate of ventilation averaged 1.7 percent it was unlikely that the rate of ventilation would affect heat production if the respiration chamber was equipped with an adequate cooling system.

Analysis of the Advanced Registry records of 611 daughters of 51 Ayrshire sires, M. H. FOERMAN and R. R. GRAVES (*U.S. Dept. Agr., Tech. Bul.* 349 (1933), pp. 59, figs. 6).—Continuing earlier work (E.S.R., 55, p. 170), a study of the milk and butterfat production of 611 daughters of 51 sires and the 452 dams of these daughters is reported from an analysis of the records in the Advanced Registry of Ayrshire cattle. The daughters showed an average in-

crease of 164 lb. in milk and 0.1 percent in butterfat as compared with their dams. There was, however, much variation in the production of the daughters of individual cows and especially among the daughters of individual sires, from which it is concluded that the cows and bulls were relatively heterozygous for the production factors.

Improvements in the production of the daughters over their dams were considerably less in the case of high-producing dams. Correlations between the dams' and daughters' production were approximately +0.26 for both milk production and fat percentage. Considerably higher correlations were obtained between the dam and daughter production of single sires. The different sires showed much variation but no relation to their ranks as determined by the daughter's production. No evidence was obtained to indicate the inheritance of sex-linked factors for milk production. The importance of progeny performance tests as indicative of transmitting ability is emphasized. It is concluded that studies of Advanced Registry records give little promise of making important contributions to the knowledge of the inheritance of milk and fat production.

Methods of hand-milking: A comparison, K. ROYES and J. McCLEMONT (*Jour. Min. Agr. [Gt. Brit.], 39 (1932), No. 6, pp. 541-544*).—A study was made to compare the following methods of milking: (1) With clean, dry hands, (2) with clean, wet hands, and (3) with clean, dry hands lubricated with vaseline.

The most striking feature of the results was the absence of *Bacillus coli* in all the samples of milk drawn with clean, dry hands. Sediment tests also showed a higher score for the milk drawn with clean, dry hands than for either of the other methods of milking.

Manganese content of milk, M. SATO and K. MURATA (*Jour. Dairy Sci., 15 (1932), No. 6, pp. 461-467*).—A method was developed at the Hokkaido Imperial University, Japan, for determining the manganese content of biological material by the colorimetric method, which avoided the interference of the precipitation of chlorides and phosphates.

The colostrum milk of cows contained considerably more manganese than did normal milk, the first sample after parturition being especially high in this element. The milk of ewes was higher in manganese than that of cows or mares. Ewe's milk tended to increase in manganese content toward the end of lactation. Normal mare's milk contained slightly more manganese than did normal cow's milk.

Zinc content of milk, M. SATO and K. MURATA (*Jour. Dairy Sci., 15 (1932), No. 6, pp. 451-459*).—A modification of the Birkner method (E.S.R., 41, p. 464) for the determination of zinc was developed at the Hokkaido Imperial University, Japan, in which the interfering iron and manganese were removed. Determinations were made of the zinc content of human, cow's, and sheep's milk at various intervals throughout the lactation period.

The analyses showed little difference in the zinc content of the different milks. During the first few days of lactation there was a marked decrease in the zinc content of the milk. The midlactation period was marked by a rather constant zinc content, but the amount increased toward the end of lactation.

Milk deficient in solids-not-fat: An investigation on a herd of cows in Hampshire, O. E. LESSER (*Jour. Min. Agr. [Gt. Brit.], 39 (1932), No. 4, pp. 340-345, figs. 2*).—A study was undertaken at the University of Reading, England, to determine whether by the addition or substitution of certain feeds the solids-not-fat content of milk could be improved.

Substituting kale in the ration of a group of cows instead of the mangolds fed to the rest of the herd brought about no appreciable improvement in the solids-not-fat content of the milk. The same was true of the addition of cod-liver oil and malt. The low solids-not-fat content was associated with an abnormally small quantity of lactose accompanied by a high chloride content. When the cows were turned on grass the lactose content increased and the solids-not-fat content returned to normal.

Observations on *Bacillus coagulans*, W. B. SARLES and B. W. HAMMER (*Jour. Bact.*, 23 (1932), No. 4, pp. 301-314).—An outbreak of spoiled evaporated milk which occurred during the abnormally hot dry weather of 1930 was investigated at the Iowa Experiment Station. *B. coagulans*, similar to the strain which yielded the original culture (E.S.R., 34, p. 78), was isolated from the spoiled milk, and the description of the organism was checked and enlarged.

Rather large numbers of organisms were found in the coagulated evaporated milk that had been stored for varying periods at different temperatures. The great viability of the organism made its isolation rather easy. The coagulated milk was much higher in total and volatile acidity than was normal evaporated milk. The nonvolatile acid of such milk was *d* lactic acid, while the volatile acid appeared to be made up of acetic and propionic acids. While the spoiled milk did not show any evidence of proteolysis, the organism greatly increased both the soluble and amino nitrogen in skim milk and in evaporated milk. There was no flavor or odor to the coagulated milk to suggest putrefaction. No free oxygen was found in the gas from cans of normal or coagulated evaporated milk, but the carbon dioxide content from the cans of coagulated milk was much higher than for the normal milk. Temperature was found to have a marked influence on the rate of coagulation of evaporated milk inoculated with *B. coagulans*.

The effect of the Electropure process of treating milk upon bacterial endospores, A. J. GELPI, JR., and E. D. DEVEREUX (*Science*, 76 (1932), No. 1974, pp. 391, 392).—Continuing the study of the Electropure process (E.S.R., 65, p. 262) at the Michigan Experiment Station, the investigations seemed to indicate that the destruction of endospores by this process was not entirely due to the heat created in the medium surrounding the endospores. Another heat factor involved in this destruction was the heat generated within the endospores. It was calculated that the temperature within the endospores was greater than that of the surrounding medium.

Bacteriological studies of a high-temperature, short-time pasteurizer, M. W. YALE (*New York State Sta. Tech. Bul.* 207 (1933), pp. 30, fig. 1).—Studies in cooperation with the New York State Department of Health were made of the bacteria found in milk before and after pasteurization by a short-time pasteurizer at 160° F. for 15 seconds and after pasteurization by the holder process at 143° for 30 minutes. In addition the samples of the same milk were pasteurized under like conditions in the laboratory. The bacteriological counts determined on standard nutrient agar plates showed that the pasteurization by the holder process was slightly more effective, the average count immediately following pasteurization being 17,200 per cubic centimeter for the former as compared to 20,600 per cubic centimeter for the latter. It was also of interest that the laboratory pasteurization methods gave approximately 50 percent lower bacterial counts than when the milk was pasteurized under commercial conditions.

Holding the milk for 24 hours at 40° to 45° reduced the count of bottled pasteurized milk from 22,800 at the time of pasteurizing to 9,600 per cubic centimeter at the end of the storage period. With the continued operation of

the high-temperature pasteurizer the counts were increased from 22,000 for the first 25 minutes of operation to 34,000 after from 30 to 90 minutes of operation. Foam collected from the layer on the surface of the milk of the pasteurizer yielded plate counts from 2 to 11 times higher than corresponding raw milk samples.

A biochemical study of irradiated milk, A. K. ANDERSON and H. O. TREIBOLD (*Jour. Dairy Sci.*, 15 (1932), No. 6, pp. 469-474, figs. 2).—A biochemical study was made at the Pennsylvania Experiment Station of milk and of butter from milk irradiated by allowing it to flow in a thin film down the inside of a cylinder in the center of which was a carbon arc having an energy emission of the wave length region from 2,800 to 3,100 Å. This method of irradiation allowed each particle of milk to receive a uniform dosage of light. Several samples were analyzed before and after irradiation.

The composition of milk showed very little change due to irradiation. Butter from such irradiated milk had a shorter induction period for oxidation than that from nonirradiated milk, and variations in fat constants were slight. Digestion trials in vitro with pepsin and trypsin indicated a slight speeding up of digestion during the early stages of the process, which may have been due to a destruction of anti-enzymes by the ultraviolet irradiation. Normal irradiation by the above method was not apt to produce any detectable change in the composition or digestibility of the milk.

Bleaching and cardboard flavor of milk, J. C. MARQUARDT (*Milk Dealer*, 22 (1932), No. 3, pp. 39, 40).—A study was undertaken at the New York State Experiment Station to determine the effect upon its color and flavor of freezing milk on the coils during cooling and subsequently exposing it to light. Holstein, Jersey, and mixed milk, both raw and pasteurized, and milk of high and low quality were used in this study.

Under the conditions of this test it was not possible to produce bleaching of milk by freezing it to the coils of the surface tubular coolers. Partial freezing to the coils did not change the flavor. Exposure to direct sunlight produced off flavors in milk in direct proportion to the intensity of the sunlight and the period of exposure. All of the milks tested acted alike when exposed to sunlight.

Dry storage of milk proving favorable (*New Hampshire Sta. Bul.* 270 (1933), p. 14).—In a study by W. T. Ackerman the precooling of milk with brine and storing in a dry storage compared favorably with immersing hot milk in cans in refrigerated water.

Certain biological factors related to tallowiness in milk and cream, P. H. TRACY, R. J. RAMSEY, and H. A. RUEHE (*Illinois Sta. Bul.* 389 (1933), pp. 577-595).—A study is reported of the relation of various conditions to the development of tallowy flavor in milk and cream. A relatively high temperature, 68-90° F., for the first part of the storage period and bacterial development seemed to decrease the tendency for the occurrence of the tallowy flavor. Contamination with copper salts such as might result from utensils tended to favor the development of this condition.

The score of butter made from cream stored for 5 days under different conditions before churning was higher when made from cream stored for 1 or 2 days at 68° F. and for 4 or 3 days at 40° than when stored for 5 days at 40°, and the latter butter showed a very tallowy flavor. Living yeast cells retarded the development of tallowiness in milk, but dead yeast cells and the filtrate from suspensions of yeast had no effect on the development of tallowiness during a storage period at 40°.

Determinations of the oxidation reduction potential of milk and cream indicated that the activity of bacteria and yeast tended to remove oxygen in their metabolic processes, and tallowiness resulted from the oxidation of the fats. A shorter incubation period of 68° at the beginning of the storage period, although increasing the bacterial count, had a favorable effect in tending to prevent the tallowy flavor. Winter milk is consequently more liable to have a tallowy flavor than summer milk.

Homogenization retarded the development of the tallowy flavor of milk due, it is suggested, to certain physical changes which make the detection of flavor more difficult.

Quantitative variations in vitamin A content of butter fat, G. S. FRAPS and R. TREICHLER (*Indus. and Engin. Chem.*, 24 (1932), No. 9, pp. 1079-1081).—Using a method previously described (E.S.R., 65, p. 294), the Texas Experiment Station undertook a study of the vitamin A content of butterfat from cows on different rations. The work was done with butterfat prepared from butter made by melting it, allowing the water, casein, and salt to settle, and then filtering.

Cows receiving grain and pasture produced butterfat containing from 17 to 50 units of vitamin A per gram. Butterfat obtained after the pasture had been dry and scanty for a number of weeks was still high in vitamin A. After a period of from 15 to 16 months on a ration of cottonseed meal and hulls, cows produced butterfat containing about 2 units of vitamin A per gram. Adding silage to the ration of cottonseed meal and hulls increased the vitamin A content of the butterfat to from about 2 to 12 units per gram, while the further addition of pasture increased the vitamin A content to about 33 units per gram.

The cows could transpose only a small quantity of the vitamin A of the feed into the butterfat regardless of the amount present in the feed. Cottonseed meal and hulls were very low in vitamin A, and sorghum silage, which was also low in this respect, produced butter low in vitamin A when fed over long periods.

The vitamin "B" and "G" content of dry skimmed milk and dry whey, R. C. BENDER and G. C. SUPPLEE (*Jour. Dairy Sci.*, 15 (1932), No. 6, pp. 445-450, figs. 5).—Using a method previously noted (E.S.R., 67, p. 187), a test was conducted to determine the vitamin B and G content of dried skim milk desiccated by the Just roller process, and of three samples of desiccated whey. The dried skim milk was subjected to temperatures varying between 240° and 258° F. for 2.5 seconds.

The growth-promoting properties of the vitamin G content were practically the same for the Just roller process dried skim milk and spray-dried whey. A marked variation in the vitamin B content of the dried skim milk and dried wheys was found, which was probably due to differences in treatment during commercial production. The vitamin B content of all the desiccated products studied was relatively lower than the vitamin G content. The nutritive value of each product was greatly enhanced by the addition of the vitamin B of rice polish and undoubtedly by other sources of the antineuritic factor.

Observations on some alcohol-soluble proteins from milk products, L. A. ALLEN (*Biochem. Jour.*, 25 (1931), No. 4, pp. 1045-1050).—At the National Institute for Research in Dairying, Reading, England, two alcohol-soluble proteins from Cheddar cheese and one from a peptic digest of caseinogen were isolated and their properties studied. These proteins differed considerably in composition from caseinogen and had a very low phosphorus content. Evidence

is presented to show that they are decomposition products of the caseinogen or the casein.

Cheese, L. L. VAN SLYKE and W. V. PRICE (*New York: Orange Judd Pub. Co.; London: Kegan Paul, Trench Trubner & Co., 1932, rev. and enl., pp. VIII+387, figs. 73*).—This is a revised and enlarged edition of the treatise previously noted (E.S.R., 58, p. 572).

Cheesemaking (*N.S. Wales Dept. Agr., Farmers Bul. 141, 2. cd. (1932), pp. 48, figs. 33*).—This is a revised edition of the publication previously noted (E.S.R., 47, p. 785).

The influence of different factors on the tendency of cheese to early gassy fermentation [trans. title], E. HAGLUND, E. SANDBERG, and C. BARTHEL (*Meddel. Centralanst. Försöksv. Jordbruksområdet [Sweden], No. 417 (1932), pp. 24, fig. 1; Eng. abs., pp. 23, 24*).—This investigation showed that it was possible by adding starters to milk intended for cheese making to prevent completely the gassy fermentation in cheese caused by aerogenes bacteria. If these additions were too large a low pH value resulted, and the resultant cheese had a friable and short consistency. The simultaneous use of starters and potassium nitrate reduced the amount of starter needed and eliminated the unfavorable effects due to the use of too much starter. Pasteurizing milk intended for cheese making to 63° C. for 10 minutes was sufficient to control gassy fermentation caused by the aerogenes bacteria. Salting the cheese in the curd greatly increased the tendency to gassy fermentation in the presence of this bacteria.

The effect of prolonged holding at pasteurization temperature on the properties of an ice cream mix, W. H. MARTIN (*Jour. Dairy Sci., 15 (1932), No. 6, pp. 481-487*).—To determine the effect of prolonged holding of an ice cream mix at pasteurizing temperature on the properties of the mix, the Kansas Experiment Station conducted a series of 5 trials with 4 mixes in each trial. A standard mix was heated to 150° F., held at this temperature for 30 minutes, 1.5, 2.5, and 3.5 hours, and a 10-gal. portion passed through the homogenizer at 2,500 lb. pressure. The mixes were aged for 24 and 48 hours before freezing. Bacterial analyses were made by the plate count method at different steps in the processing, and the mixes were also tested for viscosity, acidity, and protein stability.

The results indicated that ice cream mixes could be heated to 150° and held at that temperature for 3.5 hours without impairing the whipping properties or quality of the ice cream. There was a tendency toward a slight decrease in viscosity and an increase in protein stability as the holding period was prolonged. No serious difficulty should be encountered from heat-loving bacteria providing the processing is properly done. The majority of bacteria were destroyed after a 30-minute holding period.

A microscopic study of ice cream texture, W. C. COLE (*Jour. Dairy Sci., 15 (1932), No. 6, pp. 421-433, figs. 10*).—In this article from the California Experiment Station the author describes a method for preparing and examining samples of ice cream under the microscope. This method overcomes the inadequate illumination and the improper sectioning that has been the most common source of trouble in previous attempts to make microscopical examinations of ice cream for texture.

The study substantiates the conclusion previously drawn (E.S.R., 68, p. 665) that the rate of freezing materially affects the size of crystals formed in ice cream, and that proper methods of freezing and storing may correct many defects common to ice cream texture. It was not possible to correlate smoothness of texture as determined by size of ice crystals with size or volume of air cells.

Sandiness in nut ice creams, W. H. E. REID and M. E. POWELL (*Missouri Sta. Res. Bul. 181 (1933), pp. 19, figs. 5*).—The results are reported of eight series of tests dealing with the factors causing sandiness in ice cream and the influence of various flavors on it. The study was conducted by determining the days required for sandiness to develop. The results indicated that the factors favorable to the production of sandiness in ice cream were the presence of nuts, heat shocking, and increasing the amount of milk solids-not-fat. The factors found to retard the development of sandiness were gelatinated nuts, nut-fruit ice creams, cocoa paste, sugared nuts, boiled nuts, and autoclaved nuts, although the last two products were not recommended for mixes. It appeared that the use of maple flavoring or grapenuts had no influence upon the development of sandiness. Photomicrographs are presented to show the sugar crystals in sandy and nonsandy ice creams.

VETERINARY MEDICINE

[Report of work in New Hampshire in avian pathology and infectious abortion] (*New Hampshire Sta. Bul. 270 (1933), pp. 21-23*).—Brief reference is made to the progress of work (E.S.R., 67, p. 596) on paralysis of poultry, by C. L. Martin; coccidiosis control, by Martin, C. A. Bottorff, and T. B. Charles; storage of fowl pox vaccine, by Martin and Bottorff; infectious abortion eradication, by Martin; fowl pneumonia, by Martin and Bottorff; and pullorum disease eradication, by Bottorff.

Eighteenth report of the director of veterinary services and animal industry, I, II, P. J. du TOIT ET AL. (*Union So. Africa Dept. Agr., Rpt. Dir. Vet. Serv. and Anim. Indus., 18 (1932), pts. 1, pp. [VII]+523, pl. 1, figs. 155; 2, pp. 597-610, fig. 1, pp. 871-972, figs. 19, pp. 1005-1035, figs. 2, pp. 1037-1040, 1061, 1062, fig. 1*).—The contributions here presented (E.S.R., 67, p. 70) include the following: Bovine Anaplasmosis: A Method of Obtaining Pure Strains of *Anaplasma marginale* and *Anaplasma centrale* by Transmission through Antelopes, by W. O. Neltz and P. J. du Toit (pp. 3-20) (E.S.R., 69, p. 107); The Trypanosome Infections of *Glossina pallidipes* in the Umfolosi Game Reserve, Zululand—Preliminary Report, by A. B. M. Whitnall (pp. 21-30); A Note on *Aegyptianella pullorum* in the Fowl in South Africa, by E. M. Robinson and J. D. W. A. Coles (pp. 31-34) (E.S.R., 69, p. 114); The Immunization of Mules with Formalized Horse-Sickness Virus, by P. J. du Toit and W. O. Neltz (pp. 35-47); On the Aetiology of Heartwater, by C. Jackson and W. O. Neltz (pp. 49-70); Rabies as It Occurs in the Union of South Africa, by W. O. Neltz and I. P. Marais (pp. 71-98); East African Virus Disease in Pigs, by D. G. Steyn (pp. 99-109); Immunisation of Fowls against Fowl Pox by Use of Pigeon Pox Virus, by A. S. Canham (pp. 111-140) (E.S.R., 69, p. 112); The Occurrence of *B[acillus] oedematiens* in South Africa, by J. R. Scheuber (pp. 141-143); Goat Mange—The Infectivity of Kraals, by P. J. du Toit and G. A. H. Bedford (pp. 145-152); Wild Antelopes as Carriers of Nematode Parasites of Domestic Ruminants, Part II (pp. 153-172) (E.S.R., 67, p. 70), and *Syngamus indicus*, a New Nematode from the Indian Elephant (pp. 173-175), both by H. O. Mönnig; On a New Species of Tetrameres (*Tetrameres paradisea* sp. nov.) from Stanley Cranes (pp. 177-182) and Some Helminths from South African Chiroptera (pp. 183-196), both by R. J. Ortlepp; Distribution of *Glossina* in the Bechuanaland Protectorate, by H. H. Curson (pp. 197-219); Description of *Argas striatus*, a New Species of Tick (pp. 221, 222) and A Synoptic Check-List and Host-List of the Ectoparasites Found on South African Mammalia, Aves, and Reptilia. (Second Edition) (pp. 223-523) (E.S.R., 57, p. 77), both by G. A. H. Bedford; The Effects of Sulphur on Merino Sheep and Their Re-

sistance to Potassium Cyanide Poisoning (pp. 597-610) (E.S.R., 66, p. 110), Investigations into the Toxicity of Known and Unknown Poisonous Plants in the Union of South Africa (pp. 871-891) (E.S.R., 67, p. 70), *Chrysocoma tenuifolia* Berg. Poisoning in Angora Goats and the Development of Tolerance (pp. 893-898), A Study of the Factors Concerned in the Determination of the Toxicity of *Cotyledon orbiculata* L. (pp. 899-938), and Experiments with Potassium Cyanide on Rabbits (pp. 939-945), all by D. G. Steyn; Crotalariaiosis in Sheep, by D. G. Steyn and G. de Kock (pp. 947-953); Isolation and Chemical Examination of the Poisonous Principles of *Dimorphotheca spectabilis* Schltr. and *Dimorphotheca zeyheri* Sond., by C. Rimington (pp. 955-972); Researches into Dips and Dipping—A, Lime Sulphur Dips, Paper I, General Introduction—Lime Sulphur Dips, by H. Graf and T. J. Wilken-Jorden (pp. 1005-1014); Researches into Dips and Dipping—A, Lime Sulphur Dips, Paper II, A New Laboratory Method of Chemical Analysis (pp. 1015-1027) and Paper III, A Preliminary Study of a Colorimetric Method as a Rapid Means of Control of Polysulphide Solutions (pp. 1029-1035), both by T. J. Wilken-Jorden; The Normal Temperature of Merino Sheep during January in the Karroo and How It Is Influenced by Exercise, by J. Quinlan and G. S. Maré (pp. 1037-1040); and A Peculiar Case of Traumatism Affecting the Metatarsal Bones, by N. T. v. d. Linde (pp. 1061, 1062).

[Studies in comparative pathology, etc., in Japan] (*Jour. Japan. Soc. Vet. Sci.*, 11 (1932), No. 4, pp. 275-396, pls. 5, figs. 5).—Contributions presented (E.S.R., 68, p. 812) are as follows: Contribution to the Knowledge of the Anatomical Position of the Parathyroid Glands of the Horse, by S. Hashimoto and T. Kato (pp. 275-284, Ger. abs. p. 284); The Virulence of the Virus of the So-called "Korean Fowl Plague", by J. Nakamura, S. Oyama, and N. Tomonaga (pp. 285-301, Ger. abs. pp. 298-301); The Pathological Anatomy of "Korean Fowl Plague" Caused by a Filtrable Virus, by T. Fukushima, K. Shimomura, and S. Oyama (pp. 302-316, Japan. abs. p. 316); On the Chemical Composition of Bovine Saliva Referred to the Results of Blood Analysis, by M. Umezu (pp. 317-338, Eng. abs. pp. 336-338); Studies on Contagious Pleuropneumonia in Cattle—XI, On the So-called "Nonspecific Reaction" in the Complement-Fixation Test of Lung Plague, by S. Yamagiwa, S. Ito, and T. Inoue (pp. 339-362, Eng. abs. pp. 360-362); Studies on the Drug Refractoriness of the Rat-Bite Fever Spirochete, *Spirochaeta morsus muris*—II, Arsenic Refractoriness, by S. Akazawa (pp. 363-382, Ger. abs. pp. 380-382) (E.S.R., 62, p. 167); and Bacteria of the Paratyphoid Group Isolated from the Pig, with Particular Regard to Antigen Analysis, by T. Konno and T. Tanikawa (pp. 383-396, Japan. abs. p. 396).

Arrow grass—chemical and physiological considerations, O. A. BEATH, J. H. DRAIZE, and H. F. EPPSON (*Wyoming Sta. Bul.* 193 (1933), pp. 36 figs. 9).—Chemical and physiological tests of arrowgrass, of which *Triglochin maritima*, a plant widely distributed over Wyoming, is the dominant species, have proved conclusively that hydrocyanic acid, which occurs mainly in the leaves, is the active poisonous principle. "Poisoning of livestock, sheep, and cattle principally may occur at any time during the period of the active growth of the plant. The drying of arrowgrass results in the loss of varying amounts of hydrocyanic acid. However, the toxicity does not decrease in proportion to this loss, because when the dried material is fed the acid remaining is more readily and completely released than the acid in the original green plants. Water is the most satisfactory solvent for the extraction of the toxic principle. Ammonium sulfate (solid) precipitates a toxic complex from aqueous extracts of the plant, which, upon administration, gives physiological symptoms of arrowgrass poisoning.

"The regrowth developing from cut-over meadows is particularly important because of (1) its saline succulent character, (2) its freedom from stems and its comparatively high hydrocyanic acid content, and (3) its increasing chance of being eaten by livestock owing to the practice of grazing cut-over meadows in the late summer and fall. The occurrence of the mixed chlorides, particularly sodium chloride, is of importance, where livestock may seek out the plant to satisfy their salt requirements. The symptoms of acute arrowgrass poisoning appear to be those observed in hydrocyanic acid poisoning. Respiratory failure is the cause of death. The autopsies reveal marked asphyxia. The toxicity of the whole plant in its various stages of growth has been determined with sheep. The toxicity of various plant parts has been determined with the rabbit. Frosted, wilted, and stunted plants are less toxic than the normal bush growth. Various air-dried samples of plant or plants cured in hay do not lose their toxicity uniformly. Some samples, for unknown reasons, retain enough toxicity to make them dangerous if fed in the hay in which it naturally is found."

Three species of *Zygadenus* (death camas), O. A. BEATH, H. F. EPPSON, J. H. DRAIZE, and R. S. JUSTICE (*Wyoming Sta. Bul.* 194 (1933), pp. 39, figs. 18).—The authors show that the occurrence of death camas in Wyoming is confined to the three species *Z. gramineus*, *Z. paniculatus*, and *Z. elegans*, of which the first and last mentioned have the widest distribution.

"Chemical assays have been made to show the distribution of the alkaloids in the several plant parts at representative stages of growth. All three were found to give similar seasonal alkaloidal trends. The potency of *Z. gramineus* did not vary materially at two horizons of growth, viz, at 7,200 and 8,500 ft. elevation. *Z. elegans* was found to have a varied alkaloidal content in plants of corresponding stages of growth, but from different environments. Those taken from the Laramie Plains gave, on a 3-year average, a higher alkaloidal content than the camas plants of the higher ranges. New plants were found to originate mainly from terminal root buds. Seeds rarely gave rise to seedlings under range conditions."

It was found that if camas plants are clipped back in their early stages of growth, a response to renewed growth is rapid and in a few days normal size is obtained. On the whole, repeated clipping over a 3-year period shows (1) for the second year retarded development, (2) for the third year dwarfed and sickly plants, but alkaloidal content high initially, and (3) for the fourth year plants so small as to be barely recognizable.

"The young *Z. gramineus* and *Z. paniculatus* plants are equally toxic. *Z. elegans* at a comparable stage of growth is approximately one fourth as toxic as the other two. The very young plants and the seeds are the most toxic parts for the three species. *Z. elegans* is not a severe convulsant plant poison. The less severe distress in animals poisoned with *Z. elegans* and the lesser toxicity of this plant may indicate either that the alkaloids of this plant are less toxic or that there is the presence of a substance of an antidotal character. The crude alkaloids administered in acidic solutions (pH 2 to 4) exhibit greater toxicity than in neutral or slightly alkaline solutions (pH 7 to 8). This may be due to the greater solubility of the alkaloids in acidic solutions and hence quicker and more complete physiological absorption.

"Lambs suffer prenatal injury from severely poisoned mothers. Suckling lambs suffer no injury from the milk of poisoned mothers."

Factors which may modify precipitin tests in their applications to zoology and medicine, H. R. WOLFE (*Physiol. Zool.*, 6 (1933), No. 1, pp. 45-50).—This discussion is presented in connection with a list of 85 references to the literature.

Rotenone—a new parasiticide, D. B. CRANE (*Cornell Vet.*, 23 (1933), No. 1, pp. 15-31).—The author has found that "rotenone is nontoxic to dogs when given in amounts up to $\frac{1}{10}$ g of rotenone per kilogram of body weight. Gastritis and enteritis are caused by doses of $\frac{1}{5}$ or $\frac{1}{10}$ g of rotenone per kilogram of body weight, but this is very transitory and apparently leaves no after-effects. No symptoms of motor paralysis were observed in dogs of any age when given $\frac{1}{10}$, $\frac{1}{5}$, $\frac{1}{10}$, and $\frac{1}{5}$ g of rotenone per kilogram of body weight. Young dogs are less apt to be depressed or nauseated by very large doses than old animals. Rotenone is less apt to cause nausea when given on an empty stomach than on a full stomach. As in the case of other vermicides, rotenone is more effective when given after a period of starvation. Eighteen to 24 hours is the optimum starvation period; a longer period has no advantage.

"When given in a dosage of $\frac{1}{10}$ g per kilogram of body weight, rotenone is effective against the dog hookworm, *Ankylostoma canina*, and the roundworms *Toxascaris imbuta* and *Belascaris marginata*. Rotenone in a dosage of $\frac{1}{10}$ g per kilogram of body weight is probably of only moderate efficiency against the coccidium of dogs, but observation of a larger number of infested animals over a larger period of time is necessary before any accurate conclusions can be made. Rotenone is apparently of little or no use against the canine tapeworms. In 11 of the 13 cases in which it was used, rotenone caused an unusually rapid recovery from follicular mange. The remaining 2 cases recovered in the time usually necessary for the standard remedies."

The germicidal efficiency of sodium hydroxide, E. C. McCULLOCH (*Jour. Bact.*, 25 (1933), No. 5, pp. 469-493, figs. 6).—This contribution from the Wisconsin Experiment Station reports at length upon investigations of the germicidal efficiency of sodium hydroxide, of which high-test commercial lye was shown as a satisfactory source, when employed against nonsporulating micro-organisms. Preliminary reports on this work have been noted (E.S.R., 68, p. 815; 69, p. 107).

It is concluded that "high-test commercial lye appears to satisfy the need for a disinfectant which is suitable for use in barns and stables and which is inexpensive, odorless, and very efficient against *Brucella abortus* and related micro-organisms. The velocity of disinfection with sodium hydroxide between 25° and 2° C. is independent of temperature changes. This phenomenon appears to be correlated with the peculiar physicochemical reaction of sodium hydroxide solutions to temperature changes, wherein the ratio of the hydroxyl-ion activity to the hydrogen-ion activity increases with a decrease in temperature. The increase of the hydroxyl-ion activity over the hydrogen-ion activity at the lower temperature approximately balances the greater germicidal efficiency of each hydroxyl-ion at the higher temperature. At a given temperature, a given hydroxyl-ion concentration possesses a germicidal activity which is independent of the amount of alkali used to attain the hydroxyl-ion concentration. It is therefore concluded that the activity of the hydroxyl-ions is the most important factor in the destruction of micro-organisms by sodium hydroxide."

A list of 29 references to the literature is included.

The absence of serological relationship between *Brucella* and *Pasteurella* organisms, F. W. PRIESTLEY (*Jour. Compar. Path. and Ther.*, 46 (1933), No. 1, pp. 38-41).—The author finds that under the conditions described *Brucella* organisms are not agglutinated by *Pasteurella* sera and that *Pasteurella* organisms are not agglutinated by *Brucella* sera, there being no serological relationship between members of the two genera.

The practical value of the heat-stable antigen of *C. chauvoei* as an immunising agent, R. S. ROBERTS (*Jour. Compar. Path. and Ther.*, 46 (1933), No. 1, pp. 56-61).—The author has found that "guinea pigs can be afforded a

moderate degree of immunity against artificial infection with *O*[*lostridium*] *chauvoei* by inoculation with large quantities of the pure 'O' antigen [somatic component] of the organism. The claim that this antigen confers almost complete immunity against 100 and 1,000 lethal doses of *C. chauvoei* organisms has not been confirmed, and doubt is cast upon the value of the artificially activated spore suspension as an agent for the estimation of immunity. Immunization of farm animals by O antigen alone is unlikely to be of practical value."

The desiccation and preservation of infectious laryngotracheitis virus, C. S. GIBBS (*Jour. Bact.*, 25 (1933), No. 3, pp. 245-251, fig. 1).—In this contribution from the Massachusetts Experiment Station a laboratory method for the desiccation and preservation of infectious laryngotracheitis virus is described.

The similarity of virus pneumonia in animals to epidemic influenza and interstitial bronchopneumonia in man, H. A. MCCORDOCK and R. S. MUCKENFUSS (*Amer. Jour. Path.*, 9 (1933), No. 2, pp. 221-252, pls. 4).—This discussion is presented in connection with a list of 63 references to the literature.

Rinderpest, G. CURASSON (*La Peste Bovine. Paris: Vigot Bros., 1932, pp. 334*).—This extended account of rinderpest in 10 chapters is presented in connection with a bibliography of 38 pages. A preface by H. Vallée is included.

Biological and immunological studies of the human and the equine strains of hemolytic streptococci, I, II, S. UMENO (*Kitasato Arch. Expt. Med. [Tokyo]*, 10 (1933), No. 1, pp. 1-40, pl. 1, figs. 6).—The first part of this contribution (pp. 1-17) reports upon a comparative study of the biology of such streptococci and part 2 (pp. 18-40) upon immunology.

The biochemical characters of human and animal strains of hemolytic streptococci, P. R. EDWARDS (*Jour. Bact.*, 23 (1932), No. 3, pp. 259-266).—In investigations at the Kentucky Experiment Station aimed at discovery of a biochemical method of differentiating streptococci of human and animal origin, a brief reference to which has been noted (E.S.R., 68, p. 527), the author worked with a group of 90 strains of streptococci isolated from horses, cattle, swine, and chickens, together with 36 strains of human origin used for comparison. It was demonstrated that the animal cultures produce a higher acidity in glucose broth than do the human cultures. It was also demonstrated that 94 percent of the animal strains can be clearly differentiated from the human cultures by the fact that they produce acid from sorbitol and fail to ferment trehalose. The streptococci of human origin all ferment trehalose and fail to attack sorbitol.

Further studies on the differentiation of human and animal strains of hemolytic streptococci, P. R. EDWARDS (*Jour. Bact.*, 25 (1933), No. 5, pp. 527-536).—This is a report of work conducted at the Kentucky Experiment Station in continuation of that above noted.

In the study of 248 strains of hemolytic streptococci of human and animal origin, including 75 of human and 173 of animal origin here reported upon, the author "demonstrated that a large majority of the strains that were of animal origin, namely, 96 percent, could be distinguished from the human cultures by their action on sorbitol and trehalose. The animal strains fermented sorbitol but did not produce acid from trehalose. The human strains, on the contrary, fermented trehalose but did not attack sorbitol. The small group of animal strains which resembled the human cultures in fermentative reactions all reduced methylene blue under suitable conditions. Under the same conditions only 4 percent of the human strains reduced the dye. *Str[eptococcus] equi* was differentiated from all other human and animal strains by its inability to ferment lactose, sorbitol, or trehalose. The sorbitol-fermenting animal strains (type A) and *S. equi* regularly produced capsules. The sorbitol-

fermenting strains possessed the characters usually attributed to *S. epidemicus*. The sorbitol-fermenting strains of animal origin rarely, if ever, infect man. However, human streptococci are occasionally found in mastitis of cows."

Trichostrongylus in New York State, D. W. BAKER (*Cornell Vet.*, 23 (1933), No. 1, pp. 71-73, fig. 1).—The author reports upon cases investigated during the preceding year which indicate a rather general distribution of *T. axei* in New York State. It is pointed out that while most species of parasitic roundworms have but one or a very limited number of host species, *T. axei* has been reported from 14, including man.

Experimental infection with *Trypanosoma cruzi* from intestine of cone-nose bug, *Triatoma protracta*, C. A. KOFORD and F. DONAT (*Soc. Expt. Biol. and Med. Proc.*, 30 (1933), No. 4, pp. 489-491).—The authors conclude that *Trypanosoma triatomae* K. & McC. of the cone-nose bug (*Triatoma protracta*) in California is identical with that found in *T. megista* and in other reduviids of South and Central America known to be vectors of Brazilian human trypanosomiasis. "The determination of this identity extends the geographical range of the infected insect vector into the southwestern United States. Mammals naturally infected have not as yet been discovered in this region, but further investigation by splenectomizing suspected mammals in regions where infected bugs are found may be expected to reveal the infection."

Types of tubercle bacilli in human tuberculosis, R. M. PRICE (*Canad. Jour. Res.*, 7 (1932), No. 6, pp. 606-616).—In the work here reported a total of 14.1 percent of the 268 cases of tuberculosis in children under 14 years of age was found to be due to the bovine type, as was 3.5 percent of the 168 adult cases studied.

The toxicity of iodine for the cells of *Mycobacterium tuberculosis*, G. KNAYSI (*Jour. Infect. Diseases*, 50 (1932), No. 3, pp. 255-260).—The experiments reported show that iodine is toxic to the tubercle bacillus cells. These cells were unable to grow on slants after 30 minutes contact with as high a dilution of iodine as 1:10,000, or to infect guinea pigs after an exposure of 15 minutes to iodine in the dilution 1:5,000.

The use of iodine and of certain iodine compounds in experimental tuberculosis, G. KNAYSI (*Jour. Infect. Diseases*, 50 (1932), No. 3, pp. 261-268).—The experiments with rabbits here reported show that iodine, when administered under the conditions described, is not effective in the treatment of tuberculosis, in spite of its relatively low toxicity for the animal body and its strong germicidal action against the tubercle bacillus.

New medium and treatment for isolation of tubercle bacilli, A. M. WAHBY (*Zentbl. Bakt. [etc.]*, 1. Abt., Orig., 123 (1932), No. 7-8, pp. 504-510).—The author describes a new medium which has been developed for isolation of the tubercle bacillus and outlines a special treatment of tuberculous contaminated material. Suppression of growth of saprophytic acid-fast bacilli and prevention of spores from germination have been accomplished. Proof of the need of glycerin by the bovine type has been shown. The neutralization of the new medium with KOH has been found more desirable than NaOH.

A list of 41 references to the literature is included.

[Worms in hogs, poultry, and sheep] (*Montana Sta. Circs.* 140 (1933), pp. 8, figs. 4; 141 (1933), pp. 6, fig. 1; 142 (1933), pp. 8, figs. 5).—Practical information is here brought together by the station cooperating with the Montana Livestock Sanitary Board, dealing respectively with Worms in Hogs, Intestinal Worms in Poultry, and Intestinal Worms in Sheep.

The parasitic helminths of Canadian animals.—I, The Cestodaria and Cestoda, R. A. WARDLE (*Canad. Jour. Res.*, 8 (1933), No. 4, pp. 317-333).—The

author records 1 adult cestodarian, 53 adult Cestoda, and 24 larval Cestoda known to occur in Canadian animals. The account is presented in connection with a list of 67 references to the literature.

Protection of the rat against infection with a larval tapeworm by serum from immune rats, H. M. MILLER, JR., and M. L. GARDINER (*Soc. Expt. Biol. and Med. Proc.*, 29 (1932), No. 6, pp. 779, 780).—The results obtained in two experiments show that complete protection of the rat against the larval stage of *Cysticercus fasciolaris* and onchospheres of the tapeworm *Taenia taeniiformis* may be obtained by the injection of serum from infected rats.

Influence of age on amount of normal agglutinins in the blood of cattle, E. O. JORDAN (*Soc. Expt. Biol. and Med. Proc.*, 30 (1933), No. 4, pp. 446, 447).—The author has found that the older bovines contain in their serum specific bacterial agglutinins which are absent or very scanty in the young, and which are not likely to have been generated by infection with the specific homologous bacteria.

The most important infectious and other diseases of the milk cow and milk inspection laws, C. EHRLICH (*Die Wichtigsten Seuchen und Krankheiten der Milchkühe und das Reichsmilchgesetz. Hildesheim: Molk. Ztg.*, 1931, pp. XI+212, figs. 106).—A handbook on the diseases of the dairy cow of major importance and sanitary regulatory measures.

Anaplasmosis, I, II, G. DIKMANS (*Jour. Amer. Vet. Med. Assoc.*, 82 (1933), No. 5, pp. 739, 740, 741-748).—Observations of the occurrence of this infection in cattle in Louisiana are recorded in the first part (pp. 739, 740), followed in the second part (pp. 741-748) by a short review of its occurrence in connection with a list of 20 references to the literature and a preliminary demonstration of its identity in Louisiana.

The portals of entry of bovine infectious abortion [trans. title], K. BÜCHLI (*Tijdschr. Diergeneesk.*, 60 (1933), No. 7 pp. 337-344; *Ger., Eng., Fr. abs.*, p. 344).—The author reports having infected five young heifers with *Brucella abortus* in as many ways, namely, by mouth, by vagina, through the skin, through the teat, and through the eye.

The rapid spread of Bang's disease in an accredited herd, F. THORP, JR., and R. GRAHAM (*Jour. Amer. Vet. Med. Assoc.*, 82 (1933), No. 5, pp. 749-752, fig. 1).—The authors report upon an accredited herd in which in a period of two years approximately three fifths of the nonreacting animals of breeding age became positive to the agglutination test for *Brucella abortus*. The total number of reactors developing during this period was equivalent to approximately 80 percent of the original herd. The nonreacting unit, after 2 years, is approximately one half the size of the herd when the disease first appeared.

Infectious abortion of cattle in the Netherlands [trans. title], K. BÜCHLI (*Tijdschr. Diergeneesk.*, 60 (1933), No. 3, pp. 125-130; *Ger., Eng., Fr. abs.*, pp. 129, 130).—It is said that infectious abortion due to *Brucella abortus* occurs in all 11 Provinces of the Netherlands and on more than 40 percent of the farms, although on many the number of cows which abort is very small.

Agglutinability of homologous and heterologous strains of *Brucella* organisms during the course of *Bacillus abortus* Bang infection, R. N. NAIK (*Indian Jour. Vet. Sci. and Anim. Husb.*, 2 (1932), No. 3, pp. 262-264).—The author has found the serum of a bull infected with *B. abortus* (English strain) to give (1) against the homologous strain a positive agglutination reaction for about 5 months, a suspicious one for the next 5 months, and a negative one at about the end of a year; (2) against *B. abortus* 4 (Indian strain) more or less the same reaction as against the homologous strain, but the reaction was less marked after about 5 months; (3) against *B. abortus* 8 (Indian

strain) a positive reaction for a period of about a month and a negative one for the rest of the period; and (4) against *B. melitensis* (English strain) a positive reaction for about 5 months and then a negative one for the rest of the period.

The inter-relation of strains of *Brucella*, T. SMITH (Vet. Med., 28 (1933), No. 3, pp. 98, 99).—The author reports that in a recent study of 39 cases of abortion in cattle 17 were found associated with *B. abortus*, 5 with vibrios, 2 with *B. abortus* and vibrios, and 15 with these bacteria absent, the cause not having been determined. The importance of a thorough knowledge of the races of *Brucella* is emphasized.

Br. abortus in town milk supplies, C. S. M. HOPKIRK and D. A. GILL (Vet. Rec., 13 (1933), No. 13, p. 261).—During the last two years examinations have been made in New Zealand of composite milk samples from herds supplying cities and towns. Of 642 guinea pigs injected, 36 percent reacted positively to the agglutination test for *Brucella abortus* (bovine type) and 64 percent negatively. Upon post-mortem examination lesions were found occurring in 67.1 percent of the 231 reactors. No lesions were found in 398 of the 411 non-reacting guinea pigs, and the remaining 13 had enlarged spleens that may or may not have been due to *B. abortus* infection.

Efficacy and safety of abortion vaccines prepared from *Brucella abortus* strains of different degrees of virulence, W. E. COTTON, J. M. BUCK, and H. E. SMITH (Jour. Agr. Res. [U.S.], 46 (1933), No. 4, pp. 291-314).—Experiments are reported, in which 36 cows and heifers, all negative to the agglutination test for abortion, were used to determine the comparative immunizing value and the comparative freedom from objectionable features of different strains of *B. abortus*, the details being presented in large part in tabular form. Three strains representing three different degrees of virulence, as indicated by guinea pig inoculations, were employed. The data obtained are considered to justify the following conclusions:

"In the preparation of abortion vaccine for use in nonpregnant cattle, the virulence of the *B. abortus* strain or strains from which the vaccine is prepared is a matter of great importance, particularly when the vaccine is to be used as an immunizing agent for nonpregnant cows with functioning udders. The virulence of *B. abortus* strains for cattle can be determined with a considerable degree of accuracy by their effects on guinea pigs. Abortion vaccine prepared from strains of *B. abortus* sufficiently virulent to cause extensive lesions in guinea pigs is likely to implant the infection in the udders of nonpregnant cows and may be eliminated in the milk for long periods. Abortion vaccine prepared from strains of *B. abortus* of greatly reduced virulence, as indicated by guinea pig inoculation results, gives evidence of being reasonably efficient as an immunizing agent for abortion disease free cows and heifers when the vaccine is administered subcutaneously two months or more before service. The danger of such a vaccine being implanted in the udder of the vaccinated animal seems to be slight.

"There appears to be more danger of causing infection of the udder, in which it may persist for a long time, if the vaccine is injected intradermally than if it is injected subcutaneously; hence, the former seems to be a less satisfactory method of administration. The conjunctival method of exposure regularly transmits abortion disease to cattle."

Efficacy of an avirulent strain of *Brucella abortus* for vaccinating pregnant cattle, W. E. COTTON, J. M. BUCK, and H. E. SMITH (Jour. Agr. Res. [U.S.] 46 (1933), No. 4, pp. 315-326).—In experiments conducted with a view to determining the efficacy of an avirulent strain of *B. abortus* for vaccinating preg-

nant cattle against abortion disease, vaccines were prepared and administered subcutaneously to three pregnant cows and seven pregnant heifers. The strain of *B. abortus* used for the vaccines was isolated in 1915 from the milk of an infected cow and had undergone from 182 to 193 transfers on artificial culture media when the vaccines were prepared.

Inoculation tests showed one strain to be nonpathogenic for cattle and guinea pigs. The agglutinating value of the strain, however, was not impaired. From 1 to 2 months after vaccination 10 experiment animals were exposed to virulent strains of *B. abortus*; 9 other animals were used as controls. The vaccines gave evidence of conferring immunity against abortion disease to 40 percent of the vaccinated animals; only 11 percent of the control animals resisted the disease. No evidence was obtained to indicate that the strain becomes localized in the udders of vaccinated animals.

Vaccination against contagious bovine abortion, J. McFADYEAN (*Jour. Compar. Path. and Ther.*, 46 (1933), No. 1, pp. 50-55).—The author considers the inoculation of pregnant cows and heifers with living abortion bacilli to be indefensible.

Relationships of leucocytes and streptococci to fibrosis of the udder, G. J. HUCKER (*Amer. Jour. Pub. Health*, 23 (1933), No. 3, pp. 237-245, figs. 6).—In this contribution from the New York State Experiment Station the author finds that "milk containing more than 500,000 cells per cubic centimeter always indicates an abnormal or pathological condition in the udder. Milk containing large numbers of cells will generally continue to contain excessive numbers, while milk with a small number of cells rarely shows more than 200,000 per cubic centimeter. Variation in number of cells per cubic centimeter is greater in milk containing large numbers of cells than milk showing a smaller number. Alkaline reaction to bromothymol blue is never obtained on freshly drawn milk from a fibrosis-free quarter. When streptococci are found in aseptically drawn milk, the quarter is always indurated. All quarters free from scar or indurated tissues never show demonstrable streptococci or cells in excess of 150,000 per cubic centimeter in the milk. Not all indurated quarters show streptococci or a significant number of cells. Milk from a normal quarter or free of fibrosis does not contain long-chained streptococci or cells in excess of 150,000 per cubic centimeter."

Relation between the presence of fibrotic tissue in the udder and streptococci or cells in freshly drawn milk, G. J. HUCKER and D. H. UDALL (*Cornell Vet.*, 23 (1933), No. 1, pp. 32-39).—Contributing from the New York State Experiment Station and the department of medicine, New York State Veterinary College, the authors report having found that "udders free from indurations or scar tissue are free from demonstrable streptococci. Udders free from indurations or scar tissue are also free from cells in excess of 500,000 per cubic centimeter. In addition, these udders do not give a positive reaction to bromothymol blue. Cell counts greater than 500,000 per cubic centimeter indicate that the milk has been secured from an udder containing an appreciable amount of fibrosis. When streptococci are found in milk aseptically drawn from the udder, the quarter is always indurated. Not all indurated quarters, even when studied over a period of months, show streptococci or a significant number of cells."

Six years' experience with a herd experimentally infected with Johne's disease, W. A. HAGAN and A. ZEISSIG (*Cornell Vet.*, 23 (1933), No. 1, pp. 1-15, figs. 6).—In experimental work Johne's disease was regularly transmitted to cattle by drenching them with rather large amounts of infective materials, but in a few attempts the authors failed to infect cattle by administration of infective material intravenously. "Under conditions of severe exposure a

considerable number of animals failed to contract the disease naturally. The first naturally acquired infection did not appear in our experimental herd until 3 years after the herd had been established and over 2 years after the first scouring animal had lived in the herd. When large amounts of infective materials were given by drenching, the incubation period of the disease varied from 5 months to more than 2 years. Only 3 animals out of 9 infected in this way, showed incubation periods of less than 1 year."

While the incubation period in animals naturally infected cannot be accurately fixed, in the case of calves born in the herd in the midst of the infection (counting the period from the day of birth) the incubation period of none has been less than 2 years and in some has been over 3 years. "The state of pregnancy appears to have had a retarding influence on the course of the disease in a number of instances. Infected pregnant animals have not shown symptoms, in most cases, until after parturition. Animals infected very early in life frequently have proven sterile.

"Allergic tests, employing avian tuberculin administered intravenously, have given reasonably consistent results in our experimental herd. We believe the test is sufficiently accurate to be employed in practical control work. The complement-fixation test has been of value in our own herd and has agreed, in most instances, with the results of the allergic tests. This test is not specific for Johne's disease, however, and has proven inaccurate in many herds. The inaccuracies consist not so much in missing infected animals as in giving positive reactions with the blood of noninfected animals. The cause of these reactions is not known. Animals in advanced stages of Johne's disease frequently do not react to avian tuberculin. These animals always fix complement."

Experimental bovine mastitis, F. B. HADLEY and W. D. FROST (*Cornell Vet.*, 23 (1933), No. 1, pp. 40-46).—The authors report upon experimental inoculation of the streptococci-free udders of normal cows with various types and strains of streptococci, recovered from bovine, equine, and human sources, by an original method developed at the Wisconsin Experiment Station.

They have found that "*Str[ep]t[ococcus] epidemicus*, a beta hemolytic type, is a micro-organism that has been demonstrated to infect man, cattle, horses, and foxes. Strains from human, bovine, and equine sources proved to be the most highly pathogenic for cows of all the streptococci studied in that they were capable of causing a severe mastitis which usually resulted in destroying the function of the infected quarters.

"*S. mastitidis*, also a beta hemolytic type, is an organism occasionally found infecting cows' udders. It was shown to be capable of causing a severe and more or less chronic mastitis in the test cows. *S. infrequens* is another beta hemolytic type. The strain used was recovered from the throat of a milker (human strain); it proved to be incapable of causing mastitis although it was recovered from the milk the day following inoculation.

"*S. equi* is yet another beta type. It causes strangles in horses. It is seldom found in spontaneous cases of mastitis. We have isolated it only four times in the routine examination of many thousand samples of freshly drawn milk. In one of the three quarters exposed it secured a permanent foothold; in another it was demonstrable for about four weeks. In neither did it induce mastitis, thus indicating its low virulence for the cow's udder.

"*S. mitis*, an alpha hemolytic type, is the organism most frequently isolated by us from chronic cases of mastitis. Some of the strains were found to be capable of setting up a severe and permanent mastitis in test cows, while other strains caused only a temporary disturbance. Either the test cows had different degrees of resistance, or the organisms varied in their disease-producing

ability. Probably both factors contributed to the results, so it seems permissible to state that either different strains of *S. mitis* vary in virulence or different cows vary in susceptibility.

"A coli form bacillus was experimented with because it was found as the predominating organism in several cases of severe bovine mastitis. The strain used induced the chronic form of the disease." (See also E.S.R., 69, p. 274.)

Study of a filter-passing strain of a *Streptococcus* isolated from a case of bovine mastitis. F. H. PRISSICK (*Canad. Jour. Res.*, 8 (1933), No. 3, pp. 217-233, pls. 3, fig. 1).—The author reports that a *Streptococcus* of the viridans group obtained from a case of bovine mastitis and similar to that usually associated with chronic mastitis in cattle has under stated conditions been passed through Berkefeld N and Chamberland L 3, L 5 filters. It has been recovered from the filtrates and proved to be identical in its biological characteristics with the original unfiltered strain. Filtrates of this organism grown in K medium have given the largest number of recoveries, these being 18 out of 20, or 90 percent. Filtrates of growth in nutrient broth were recovered in 1 out of 20 filtrations, or 5 percent.

The trichomonad disease of cattle and the vaginal catarrh problem [trans. title], ABELEIN (*München. Tierärztl. Wchnschr.*, 83 (1932), Nos. 22, pp. 253-257; 24, pp. 279-285; 25, pp. 292-296; 26, pp. 305-309; 27, pp. 318-322, figs. 3; abridged trans. in *Cornell Vet.*, 23 (1933), No. 1, pp. 47-58).—It is concluded that the granular or nodular venereal disease and the vesicular venereal disease cause relatively limited losses, and that the trichomonad disease is a wholly unrelated, specific malady of major importance. The review is by W. L. Williams.

Experimental erysipeloethritic arthritis in lambs. H. MARSH (*Journ. Amer. Vet. Med. Assoc.*, 82 (1933), No. 5, pp. 753-766, figs. 6).—In this contribution from the Montana Experiment Station the author reports having found that "a chronic arthritis, corresponding in every way to the naturally occurring disease, can be produced in lambs by inoculating *Erysipelothrix rhusiopathiae* intravenously or into the umbilical cord. The typical disease can be produced by exposing the stump of the umbilical cord, the docking wound, or the castration wound to soil which has been impregnated with cultures of *E. rhusiopathiae*. Agglutinins for *E. rhusiopathiae* are produced in the blood of both naturally and artificially infected animals.

"A comparison of three methods of docking indicates that infection is much less likely to occur following docking with the hot iron than with the knife or the emasculator. The experimental results are confirmed by field experience with docking methods. The experimental results correlated with field experience justify the conclusion that the principal portals of entry of this infection are the umbilical cord at birth and the docking and castration wounds. Preventive measures include lambing sanitation, navel disinfection at birth, docking on grass if possible, and docking with the hot iron in some form."

An extreme case of urinary calculi in a lamb. J. F. BULLARD (*Jour. Amer. Vet. Med. Assoc.*, 82 (1933), No. 5, pp. 774-776, fig. 1).—This is a contribution from the Indiana Experiment Station.

A parasitological field trial on "Gundowringa", New South Wales, 1932. I. C. ROSS and N. P. GRAHAM (*Jour. Council Sci. and Indus. Res. [Aust.]*, 6 (1933), No. 1, pp. 26-31).—This is a report of the second year's work (E.S.R., 67, p. 601) aimed at the control of losses from internal parasites of sheep.

"Corriedale ewe lambs, grazed on improved pasture, both with and without anthelmintic treatment, and with and without rotation of pastures, at the rate of 2.5 and 3 sheep per acre, respectively, made very much greater average gains

in live weight and produced from 1.75 to 2.5 lb. more wool per head than sheep on natural pastures at the rate of 1 sheep per acre. The average gain in live weight was 14 lb. per head and per acre on natural pasture; while on improved pasture, without rotation, it was 49 lb. per head and 122.5 lb. per acre, and on improved pastures, with rotation, it was 51 lb. per head and 153 lb. per acre. Sheep on natural pasture produced, on an average, 9 lb. 2 oz. of wool per head and per acre, while on improved pasture up to 11 lb. 13 oz. per head and 35 lb. per acre were produced. The sheep on improved pasture, and treated with an anthelmintic (carbon tetrachloride) at monthly intervals did not show any increase in body weight in comparison with sheep on similar pasture but not treated with an anthelmintic. The sheep on improved pasture, treated with an anthelmintic (carbon tetrachloride), showed a material increase in the weight of fleece produced per head in comparison with untreated controls. The effect of improved pastures on wool character was to produce a slight lowering in the count, but such wool was estimated to give as high, or higher, percentage clean scoured yield as that from natural pasture, and was of better staple length."

On some nematode parasites of goats and sheep at Muktesar, G. D. BHALERAO (*Indian Jour. Vet. Sci. and Anim. Husb.*, 2 (1932), No. 3, pp. 242-254, pls. 4).—Seven parasites are here considered, namely, *Varestrongylus pneu-monicus* n.g. and sp., *Dictyocaulus unequalis* n.sp., *Ostertagia orientalis* n.sp., *O. occidentalis* (Rans.), *O. circumcincta* (Stadelm.), *Haemonchus contortus* (Rud.), and *Oesophagostomum venulosum* (Rud.).

Diseases affecting moose, R. FENSTERMACHER and W. L. JELLISON (*Minnesota Sta. Bul.* 294 (1933), pp. 20, figs. 7).—The disease of moose occurring in Minnesota, reported upon by Cahn, Wallace, and Thomas (E.S.R., 69, p. 110), has been studied by the authors continuously since April 1924. Their report includes a review of the literature, its history, symptomatology, post-mortem findings, blood studies, bacteriological and serological findings, and microscopic anatomy, and is followed by a general discussion.

The findings to date have been almost entirely negative so far as determining the cause of sickness and death among moose. Necropsy findings give no suggestions as to the cause of the sickness. Bacteriological findings are also negative, as are the results of animal inoculations. The possibility that the ticks may be a vector of some bacterial or protozoan disease is fully recognized. The transmission of the infection to guinea pigs and rabbits has failed.

The longevity of *Brucella suis* in artificially contaminated anti-hog cholera serum, S. E. PARK and R. GRAHAM (*North Amer. Vet.*, 13 (1932), No. 12, pp. 26-30).—In work at the Illinois Experiment Station it was found that "clear anti-hog-cholera serum (0.5 percent phenol) artificially inoculated with two *B. suis* strains (36,000 to 84,000,000 organisms per cubic centimeter) and stored at room and ice box temperatures did not yield viable *Brucella* after 8 days.

"Whole blood anti-hog-cholera serum (0.5 percent phenol), similarly inoculated (43,000,000 to 84,000,000 *Brucella* organisms per cubic centimeter), did not yield viable *Brucella* at room temperature after 45 days. *B. suis* remained viable, however, in such serum at ice box temperature for over 82 days.

"Freshly defibrinated hog blood (phenolized 0.5 percent) inoculated with *B. suis* (74,000,000 to 80,000,000 organisms per cubic centimeter) did not yield viable organisms after 11 days at room temperature. However, at ice box temperature one *Brucella* strain in these samples remained viable for 25 days."

A list is given of 14 references to the literature.

An account of the occurrence of hog erysipelas infection in New York State. D. W. BAKER (*Cornell Vet.*, 23 (1933), No. 1, pp. 66-70).—A report of cases of swine erysipelas in New York State diagnosed in December 1932.

Swine erysipelas. J. S. FULTON (*Canad. Jour. Res.*, 8 (1933), No. 4, pp. 312-316, figs. 2).—The author reports that swine erysipelas has been recognized in widely separated districts in Saskatchewan, the disease having appeared in the acute, subacute, and chronic forms. The causative organism (*Erysipelothrix rhusiopathiae*) has been isolated from a number of cases, and positive serological reactions have been obtained in others.

Idiopathic hemorrhagic hepatitis of swine. A. H. QUIN, JR., and J. D. SHOEMAN (*Jour. Amer. Vet. Med. Assoc.*, 82 (1933), No. 5, pp. 707-717, figs. 4).—The authors report upon a peculiar etiologically obscure disease of swine which occurred in a herd in Dallas County, Iowa, in the summer of 1931. Thirty-two otherwise healthy pigs in a herd of 130 died, after an average illness not exceeding 2 days, with a disease characterized by septicemia, gastroenteritis, and hepatomegaly, with intralobular hemorrhage and necrosis. In the absence of positive bacteriological findings and negative results from inoculation of 3 cholera-susceptible pigs, the disease was classified as true toxemia of unknown etiology.

Five cases of hypertrichosis partialis in swine. H. C. H. KERKAMP (*Cornell Vet.*, 23 (1933), No. 1, pp. 74-76, fig. 1).—This contribution from the Minnesota Experiment Station reports upon five cases of hypertrichosis partialis observed in a litter of seven pigs.

The viability of the virus of swine fever in bone marrow, muscle, and skin of preserved carcasses. T. M. DOYLE (*Jour. Compar. Path. and Ther.*, 46 (1933), No. 1, pp. 25-37).—Experiments have shown that the virus of hog cholera survived 73 days in the bone marrow of "salted" and "chilled" carcasses. The virus survived 17 days in the skin and muscle of pigs killed before the appearance of clinical symptoms. There was some evidence that virus was still present in salted muscle after 73 days. The virus survived 42 days in salted skin and muscle of pigs killed after the appearance of clinical symptoms. The virus survived for 37 days in bone marrow and muscle, and for 19 days in skin, of "smoked" carcasses.

Dissecting aneurysms in swine: A report of two cases. H. C. H. KERKAMP (*Cornell Vet.*, 23 (1933), No. 1, pp. 76-81, figs. 2).—Contributing from the Minnesota Experiment Station, the author presents two case reports of dissecting aneurysm in swine, one a Chester White sow approximately 20 months of age, weighing 300 lb., and the other a Poland China barrow 227 days old, weighing 170 lb.

Development of the nodular worm, *Oesophagostomum longicaudum*, in the pig. L. A. SPINDLER (*Jour. Agr. Res. [U.S.]*, 46 (1933), No. 6, pp. 531-542, figs. 10).—Pure cultures of infective larvae of *O. longicaudum* were fed to pigs raised free from the parasite in order to trace its development in its definitive host. Forty-eight hours after such infestation encysted third-stage larvae were found in the colon of the experimental animal; the cysts were surrounded by areas of intense inflammation with liquefaction of tissues. "In sections the cysts, the exact nature of which has not been definitely determined, appeared to be composed of a smooth homogenous substance containing neither striations nor nuclei, and easily distinguishable from the surrounding tissue. Inflamed nodules were found in the colon of an animal which had been infected 10 days prior to post-mortem examination. Within the nodules the parasites were enclosed in cysts which were much larger than those found in the earlier stages of infection. The cyst walls appeared to be of the same composition

as those observed in the earlier stages of infection and were easily distinguishable from the surrounding fibroblasts. No decrease in thickness of the cyst walls was noted, the increase in diameter of the cysts apparently being the result of rupture by the parasites, followed by subsequent repair.

"On post-mortem examination of an animal 17 days after infection, fourth-stage larvae and early fifth-stage worms were recovered from the lumen of the cecum and large intestine. Late fourth-stage larvae were found in the nodules and in the act of emerging from the nodules, a fact which indicated that the larvae enter the lumen of the colon in the late fourth or early fifth stage of development. Nodules from which the parasites had emerged were smaller and less inflamed than those that still contained larvae. In sections, the cysts inside the empty nodules were seen to be broken, apparently having been ruptured by the parasite when it emerged.

"After the emergence of the parasites, the nodules which at first were highly inflamed and contained a central necrotic area appeared to decrease in size and in degree of inflammation. At the end of 35 days the nodules had almost completely disappeared, their location being marked, in section, by masses of connective tissue, leucocytes, and giant cells.

"Sexual maturity, as indicated by the appearance of eggs in the feces of experimentally infected animals, was reached by the parasites in 50 to 53 days after infection."

A brief description is given of the larval stages recovered from the intestines of infected animals.

Brucella abortus in the horse, H. M. DUFF (*Jour. Compar. Path. and Ther.*, 46 (1933), No. 1, pp. 42-46).—The author reports that "an organism isolated in pure culture from a withers abscess in a horse proved to be indistinguishable microscopically, culturally, and serologically from *B. abortus*. The blood serum and abscess fluid from the horse under observation agglutinated various *B. abortus* antigens up to, and including, 1 in 500. The same titer was observed when a suspension of the organism from the abscess was used. The coarse character of the culture growth and the marked tendency to agglutinate spontaneously in the presence of salt solutions seem to indicate that the organism is a rough strain of *B. abortus*."

Is there a filtrable virus of abortion in mares? (*Kentucky Sta. Bul.* 333, *Sup.* (1933), pp. 2).—This is a report of observations which supplement part of the account (pp. 297-301) by Dimock and Edwards (*E.S.R.*, 69, p. 111). In December 1932 and the first three months of 1933 a severe, clear-cut outbreak that resembled closely the apparently noninfectious abortion previously studied occurred on a farm near Lexington, Ky., 24 of 32 pregnant mares aborting. The period of gestation of the mares that aborted was between the seventh and tenth months, the great majority about the eighth month. The clinical condition of the mares before and after abortion, the promptness with which the majority of them returned to normal, the absence of cultivable micro-organisms, and the pathology of the fetal tissues resembled those conditions observed in previous outbreaks.

In experimental work 3 of 4 pregnant mares injected and fed material from aborted fetuses aborted. Since the period of incubation was practically the same in all cases, the results strongly indicate the presence of an infectious agent in the inoculum. Since only 1 mare was inoculated with filtrate, the result cannot be accepted as final that the abortion was directly due to the action of a filtrable agent.

Encephalomyelitis of horses in Colorado, I. E. NEWSOM (*Vet. Med.*, 28 (1933), No. 4, pp. 132-135, figs. 4).—Contributing from the Colorado Experiment

Station, the author reports that encephalomyelitis of horses, which was first recorded from the San Joaquin Valley of California in 1931 (E.S.R., 66, p. 74), has appeared in Colorado on three occasions. The details are presented in connection with a chart showing its distribution in the State in 1932.

Mosquitoes as vectors of the virus of equine encephalomyelitis, R. A. KELSER (*Jour. Amer. Vet. Med. Assoc.*, 82 (1933), No. 5, pp. 767-771).—The author considers the results reported, coupled with epizootological observations, to indicate that equine encephalomyelitis is naturally transmitted by insect vectors, and very probably mosquitoes. While it is understood that the particular species of mosquito (the yellow-fever mosquito) which was used in the experiments is not likely to be found in a number of the areas where encephalomyelitis has been enzootic, other species of this same genus (*Aedes*) do occur in such areas and in all probability are as capable of transmitting the disease as the yellow-fever mosquito.

Infections of fetuses and foals, W. W. DIMOCK and P. R. EDWARDS (*Jour. Amer. Vet. Med. Assoc.*, 82 (1933), No. 5, pp. 718-725).—In a study at the Kentucky Experiment Station of "streptococci isolated from genital infections and prenatal diseases of the horse, the organisms were found to possess the characters that in the past have been generally attributed to human streptococci. The cultures were strongly hemolytic in fluid media, did not hydrolyze sodium hippurate, produced only a low acidity in glucose broth, and failed to reduce methylene blue. It was found possible to differentiate 95 percent of these cultures from streptococci of human origin by their fermentative reactions. All of a series of 75 human strains were able to ferment trehalose, while they failed to ferment sorbitol. In a series of 135 equine cultures, 129 were able to attack sorbitol but failed to ferment trehalose. The 6 remaining cultures resembled the human strains in their action on fermentable substances.

"In our study of streptococci from cows, hogs, chickens, and foxes, these were found to resemble the group of equine strains described above; 95 percent of them fermented sorbitol but failed to attack trehalose. *Streptococcus equi* can be distinguished from the human streptococci and the other animal strains by the fact that it ferments neither trehalose nor sorbitol." (See E.S.R., 69, p. 111.)

Agglutinability of different strains of *Bacillus mallei*, R. N. NAIK (*Indian Jour. Vet. Sci. and Anim. Husb.*, 2 (1932), No. 3, pp. 274-277).—A study made by the author of the agglutinability of three strains of *B. mallei* failed to show any difference.

Agglutination reaction due to mallein injections in horses, R. N. NAIK (*Indian Jour. Vet. Sci. and Anim. Husb.*, 2 (1932), No. 3, pp. 265-273).—The author finds that "no sharp demarcation can be made out between the agglutination titers of serum from horses recently injected with mallein and of serum from horses infected with glanders. The presence of agglutinins induced by an injection of mallein may be found only up to about two months following the date of injection. If a healthy horse is subjected to repeated injections of mallein, the agglutination reaction simulating that of a positive case of glanders is noticeable a week after the first injection. Repeated injections of mallein do not increase the titer above that which is obtained a week after the first injection. The presence of specific agglutinins in the blood serum of horses repeatedly injected with mallein does not persist longer than three weeks after the last injection."

Necrobacillosis in the horse [trans. title], A. CLARENBURG and T. VAN HEELSEN (*Tijdschr. Diergeneesk.*, 60 (1933), No. 5, pp. 240-244, fig. 1; *Ger., Abg.*,

Fr. abs., p. 244).—The authors report that upon post-mortem examination of a horse which had died they found necrotic foci in its liver and lungs, from which *Bacillus necrophorus* was isolated. It is considered probable that the infection of the liver took place from the intestine by way of the portal vein, and that the lungs became infected through the blood from the liver.

[Report of "Field" Distemper Fund] (*Field* [London], *Sup. Feb. 4, 1933*, pp. XII, figs. 36).—The contributions presented include the following: The Fight against Distemper: How It Has Been Conquered with the Assistance of the "Field" Distemper Fund, by F. Hobday (pp. I, III), and The Story of a Great Success: The "Field" Fund and Its Foundations, by E. S. Grew (pp. III, V).

The susceptibility of cloacal tissue to the virus of infectious bronchitis, C. B. HUDSON and F. R. BEAUDETTE (*Cornell Vet.*, 23 (1933), No. 1, pp. 63-65).—This contribution from the New Jersey Experiment Stations reports upon the finding of the proctodeum tissue of the cloaca to be attacked by the virus of infectious bronchitis (*E.S.R.*, 67, p. 747). Birds which recover from cloacal inoculation are shown to be immune to tracheal inoculation, and birds which recover from tracheal inoculation to be immune to cloacal inoculation. An account of immunization work with this disease has been noted (*E.S.R.*, 69, p. 279).

Fowl paralysis (neurolymphomatosis gallinarum) in chicks under three months of age, J. BIELY, V. E. PALMER, and I. M. LERNER (*Canad. Jour. Res.*, 8 (1933), No. 4, pp. 305-311, fig. 1).—The authors present information on cases of fowl paralysis in which 45 out of 244 chicks developed clinical symptoms before they were 90 days of age. "Of these, 20 were inoculated and 25 were not inoculated. Forty-two of the 45 chicks (93.3 percent) showed lesions in the nervous system. Nine chicks (20 percent) showed lymphomatous tumors. Seventeen of the 45 cases (37.7 percent) occurred in chicks less than 60 days of age; the same number of cases occurred between 60 and 74 days of age; and 11 cases (24.4 percent) occurred between 75 and 89 days of age. The mean age of all chicks that developed paralysis was 64.4 days. The fact that typical fowl paralysis occurred in one chick at 37 days and in several from 40 to 44 days of age would indicate that the disease may develop at a very rapid rate."

Pullorum disease control with special reference to incubator disseminated disease, R. GRAHAM (*Vet. Alumni Quart. [Ohio State Univ.]*, 20 (1933), No. 4, pp. 177-188, figs. 2).—In summarizing this contribution, the author emphasizes the necessity in the suppression and control of incubator-disseminated pullorum disease for cooperation by veterinarians and hatcherymen in the dispatch of the following fundamental problems of poultry hygiene: (1) Elimination of pullorum disease in breeding flocks, (2) clean incubators and incubator rooms, and (3) disinfection of trays and fumigation of incubators.

A preliminary report of an apparently new respiratory disease of chickens, J. P. DELAPLANE, H. O. STUART, and H. BUNYEA (*Jour. Amer. Vet. Med. Assoc.*, 82 (1933), No. 5, pp. 772-774, fig. 1).—The authors report upon an apparently new respiratory disease which made its appearance the latter part of June 1932 almost simultaneously in several poultry establishments in various sections of Rhode Island, the observations having been made by the Rhode Island Experiment Station and the U.S. Department of Agriculture cooperating. It was later observed in two flocks of pheasants in that State.

The disease is of a contagious nature, having spread rapidly throughout the flocks investigated. It is characterized by an exudative rhinitis and sinusitis, there having been no appreciable or consistent involvement of the larynx,

trachea, or bronchi. However, the visible membranes of the eye were subject to marked degrees of inflammation, manifested by reddening, swelling, and photophobia, with more or less profuse foamy lacrimation. In the course of one or more days, this lacrimation would give way to a sticky mucofibrinous or mucopurulent exudation, which tended to glue the eyelids. Profuse exudates of a similar character, although sometimes bloodstained, were manifested in the nasal tract and sinuses. In some few cases a generalized edema of the regions of the head and neck was noted. The subcutaneous swellings, particularly those around the eyes, were somewhat discolored, being slightly yellowish-green in character.

The incubation period in the cases observed appeared to be two or three days. The disease spread with great rapidity in infected flocks, and the death rate was high, particularly in young fowls, with the same general train of symptoms. Thus far, no pathogenic organisms capable of reproducing the disease have been isolated from the organs or air passages. A number of attempts to determine whether the virus is filtrable met with negative results. Cross-immunity tests to determine whether there was any connection between the virus of laryngotracheitis and the new disease show that fowls that have recovered from laryngotracheitis are susceptible to the new disease, and fowls that have recovered from the new disease are susceptible to laryngotracheitis. Inoculations of the pigeon, turkey, sparrow, and crow with the virus of the new disease have given negative results.

Transmissible tumors of the fowl, A. CLAUDE and J. B. MURPHY (*Physiol. Rev.*, 13 (1933), No. 2, pp. 246-275).—This contribution from the laboratories of The Rockefeller Institute for Medical Research is presented in connection with a bibliography of 15 pages.

On three species of the genus *Capillaria* from the English domestic fowl, D. O. MORGAN (*Jour. Helminthol.*, 10 (1932), No. 4, pp. 183-194, figs. 17).—The three species here reported upon are *C. longicollis* (Rud.) Trav., *C. columbae* (Rud.) Trav., and *C. retusa* (Rall.) Trav.

Chloral hydrate as a general anaesthetic for the fowl, N. HOLE (*Jour. Compar. Path. and Ther.*, 46 (1933), No. 1, pp. 47-49).—Chloral hydrate has been found useful as a general anesthetic for the fowl, its intravenous injection being simple and with no after-effects.

Arsenic poisoning in poultry, A. L. WEBER, F. R. BEAUDETTE, and C. B. HUDSON (*North Amer. Vet.*, 13 (1932), No. 12, pp. 46, 47).—Contributing from the New Jersey Experiment Stations, the authors deal with losses which occurred in a lot of 700 pullets due to arsenical poisoning that apparently was intentionally administered. Mention is also made of an additional case of poisoning in the fowl and of one which occurred in a flock of geese and chickens.

Toxicity, distribution, and excretion of thallium, P. A. SHAW (*Soc. Expt. Biol. and Med. Proc.*, 30 (1933), No. 4, pp. 488, 489).—The author has found that thallium sulfate administered by mouth to quail, geese, and ducks is fatally toxic in doses of 12, 15, and 30 mg per kilogram, respectively, calculated as thallium metal. Thallium in liver, kidney, heart, and osseous tissue was estimated to be present in a concentration approximately equal to that which had been administered. Muscular tissue was found to acquire a considerably higher concentration of thallium, but fat contained practically none. Analysis of the tissues of a goose dying 15 days after the oral administration of 20 mg per kilogram indicated a retention of from 35 to 70 percent of the thallium given.

It is concluded that while thallium is very slowly excreted and the edible tissue of birds seems to retain a relatively large amount of ingested thallium, there is no great danger that secondary poisoning in man might result from the

eating of game birds poisoned with thallium. A relatively large amount of such flesh would be necessary to contain a toxic dose of thallium for man.

***Tetrameres crami* sp. nov.**, a nematode parasitizing the proventriculus of a domestic duck in Canada, W. E. SWALES (*Canad. Jour. Res.*, 8 (1933), No. 4, pp. 334-336).—Under the name *T. crami* the author describes a new nematode parasite of the duck taken at Ottawa, Canada.

Observations on the fertility and hatchability of eggs from turkeys affected with enterohepatitis, C. F. SCHLOTTHAUER and H. E. ESSEX (*Cornell Vet.*, 23 (1933), No. 1, pp. 81, 82).—In experiments conducted at the Mayo Foundation at Rochester, Minn., to test the possibility of the transmission of enterohepatitis infection through the egg and to obtain data regarding the fertility and hatchability of eggs from known infected turkeys, it was found that 42 percent of the 62 eggs from infected turkeys were infertile as compared with 15 percent of 310 eggs from a flock of healthy turkeys. In the diseased turkeys 52 percent of the fertile eggs contained dead embryos in various stages of development as compared with 25 per cent of those from the healthy fowls. Twenty-seven percent of the eggs from the diseased hens hatched as compared with 63 percent from the healthy hens.

AGRICULTURAL ENGINEERING

[Agricultural engineering investigations at the Maine Station] (*Maine Sta. Bul.* 363 (1932), pp. 265, 266, 294-296, fig. 1).—The results of examinations of gasolines and motor oils, by J. M. Bartlett, C. H. White, and B. E. Plummer, and brief descriptions of a cold storage for apples at the Highmoor Farm and a greenhouse at the main station are presented.

[Irrigation investigations in Oregon] (*Oregon Sta. [Pamphlet, 1933]*, p. 12; *Branch Sta. [Pamphlets, 1933]*—*Harney Sta.*, pp. 3, 4, 6, fig. 1; *Umatilla Sta.*, pp. [2-4]).—These pamphlets report briefly the outstanding accomplishments resulting from irrigation investigations at the main station; results of experiments on an irrigated 80-acre farm unit under pump and duty of water experiments with several grain, forage, and truck crops at the Harney Substation; and results of studies with strip border method of irrigation and of lysimeter tests at the Umatilla Substation.

Computing the effective diameter of a well battery by means of Darcy's law, O. L. ELIASON and W. GARDNER (*Agr. Engin.*, 14 (1933), No. 2, pp. 53, 54, figs. 3).—In this mathematical contribution from the Utah Experiment Station, an attempt is made to compute the effective diameter of a battery of wells penetrating a uniform horizontal stratum of water bearing gravel bounded above and below by impervious layers with the water pumped from such depth as to insure horizontal movement.

Water power on the farm, D. S. WEAVER (*North Carolina Sta. Agron. Inform. Circ.* 74 (1932), pp. 6, figs. 3).—Practical information is given on how to develop and utilize water power on farms in the Piedmont and Mountain sections of North Carolina.

Some soil factors affecting erosion, L. D. BAVER (*Agr. Engin.*, 14 (1933), No. 2, pp. 51, 52).—In a contribution from the Missouri Experiment Station an analysis is given of the soil factors affecting erosion, including absorptive capacity for water, permeability of soil profile, ease of dispersion, size of particle, and degree of aggregation. From this analysis a mathematical expression of erosion as a function of soil properties is derived $E = \frac{K D}{A P p}$ in which E is erosion, K is a constant of proportion, D is the ease of dispersion, A is absorptive capacity, P is permeability, and p is size of particle.

Data are reported on the effect of a legume in the rotation in the control of erosion between terraces.

Soil erosion control by terracing—history and accomplishments, C. E. RAMSEY (*Agr. Engin.*, 14 (1933), No. 4, pp. 103, 104, fig. 1).—In a contribution from the U.S.D.A. Bureau of Agricultural Engineering the history and accomplishments of terracing as an erosion control measure are briefly summarized.

The results given in this article on soil erosion control are by no means conclusive, but the data so far collected clearly indicate that terraces well designed and well constructed are very effective in reducing the rate of soil erosion.

Protective coverings for rammed earth walls, R. L. PATTY (*Agr. Engin.*, 14 (1933), No. 3, p. 70, figs. 2).—Studies conducted at the South Dakota Experiment Station are briefly reported. It was found that rammed earth walls can not only be painted satisfactorily within three days after being rammed, but that painting at that time is very desirable. So far this study has shown that the blocks painted immediately do lose their moisture but at a slower rate.

Efficiency tests of tractor wheels and tracks, E. V. COLLINS (*Agr. Engin.*, 14 (1933), No. 2, pp. 35-38, figs. 7).—Studies conducted at the Iowa Experiment Station on the performance of tractor wheels and tracks over their normal working range as means of converting power from the final drive shaft to the drawbar are reported.

In the tests of tractor tracks the equipment used consisted of a Caterpillar 20 tractor with a recording and integrating dynamometer built into the front support for the engine and transmission, which are of unit construction. The dynamometer car used for providing a load for these tests has a pair of guide wheels in front and tracks in the rear. A large rotary pump which provides the necessary resistance to travel is geared to the tracks. The valve of the pump is operated automatically to provide a constant drawbar pull. The hitch is connected directly to a large piston working against oil pressure provided by a second pump. A relief valve set to give the desired pressure on the piston by-passes the surplus oil back to a reservoir. In this way a constant pressure is maintained on the piston attached to the hitch.

The efficiency curves for four different heights of hitches for pulverated soil show the advantage of a low hitch. This held true for all conditions tested except hard cinders where the 12-in. hitch gave the best results. Perhaps in this case more penetration of the hard surface was secured by tilting the tracks up slightly. Other tests made indicated that used tracks had less friction than new ones, and that at least half the rolling resistance would be saved if the track were laid out for it instead of having to pick up and relay its own track.

In the tractor wheel tests a John Deere Model D tractor was selected because the design of the final chain drive appeared to offer an excellent opportunity to attach an input measuring device. In this case an integrating dynamometer was used to measure the tension in one of the final drive chains. With this tractor, using 46 by 11 in. wheels and 5-in. spade lugs, the higher hitches gave the best results.

Ohio tests of rubber tractor tires, G. W. MCCUEN (*Agr. Engin.*, 14 (1933), No. 2, pp. 41-44, figs. 7).—Tests of rubber tractor tires conducted at the Ohio Experiment Station are reported. The purpose was to ascertain the relative efficiencies of the same tractor when equipped with regular wheel equipment and low-pressure tire equipment. The steel wheels were the standard

42 by 11½-in. wheels with 6-in. spade lugs on the rear and 28 by 4 plain band type in front. The rubber equipment consisted of Firestone 11.25-24 pneumatic tires on the rear and 6.50-16 on the front. The rear tires were inflated to 12 lb. and the front tires to 16 lb. pressure.

At normal working loads the rubber tractor tires in second gear required an average of only 91 percent and in third gear only 75.5 percent as much gasoline per drawbar horsepower as the steel wheels in second gear. The greater efficiency of the rubber tires makes it practical to do work in third gear which could be done only in second or first gear with steel wheel equipment. Under all conditions tested the rubber tractor tires developed a greater effective drawbar pull than the steel wheels with lugs. The low-pressure tractor tires gave a higher average speed than steel wheels. For the same effective drawbar pull the average increase in speed on sod in one series of tests was 36.7 percent and on plowed ground 25.9 percent. This higher speed would of course result in a corresponding saving in time.

The rolling resistance of the tractor when equipped with low-pressure tractor tires on sod is 31.4 percent and 54.1 percent of that of steel wheels. This low rolling resistance is a large influencing factor in a greater efficiency of the tractor. The power of the engine is not consumed to so large a degree in the propelling of the unit but is delivered to the drawbar as useful work.

A greater efficiency of the tractor was obtained when pneumatic tractor tires were used as wheel equipment for plowing. This increased efficiency was a result of lowering the fuel consumed per acre plowed 23.83 percent and increasing the area plowed by 27.2 percent in the same unit of time.

Drilling powdered agricultural limestone, W. A. ALBRECHT and M. M. JONES (*Agr. Engin.*, 14 (1933), No. 4, pp. 106, 107, fig. 1).—The results of experiments conducted at the Missouri Experiment Station are briefly reported. These indicate that the internal double-run type of force feed will drill fine limestone when a suitable agitator is used in the drill hopper. They also indicate that present drilling machinery will distribute the finely powdered limestone effectively and in rates that easily accommodate the amounts suggested by soil experiments with this fine limestone.

Recent cotton ginning investigations, C. A. BENNETT (*Agr. Engin.*, 14 (1933), No. 3, pp. 74-76, figs. 2).—This is a summary of some of the more important features of the cotton ginning investigations being conducted at the Mississippi Delta Branch Station by the U.S.D.A. Bureau of Agricultural Engineering. The results are taken to indicate that there is ample foundation for the use of the plain single-rib gin in many localities, and especially for the longer staples where the cleaning and extracting is performed prior to the actual ginning.

A grain combine for the Corn Belt, I. D. MAYER (*Agr. Engin.*, 14 (1933), No. 4, pp. 91, 92, 96, figs. 2).—This contribution from the Indiana Experiment Station directs attention to some of the difficulties which have been experienced with the combines now in use in this region, and sets out some of the requirements which a combine should fulfill in order to be a satisfactory machine for Corn Belt conditions.

It has been found that the combine desired by the farmers of the Corn Belt is one with great flexibility. It should be capable of harvesting a great variety of crops; it should have a wide cutting range; it must have sufficient capacity to handle long and coarse-strawed grain; it must be strong and durable, yet relatively light in weight so that it can be pulled over soft fields by the medium size of tractor; it should be capable of quick, easy transportation

from field to field; and it should be a simple machine which can be kept in adjustment and repair by the farmer.

A cost study of filling silos with the field ensilage harvester, P. I. WRIGLEY and A. W. CLYDE (*Agr. Engin.*, 14 (1933), No. 4, pp. 97, 98, 100, figs. 2).—Studies conducted at the Pennsylvania Experiment Station are briefly reported.

Practically no difference was found between the corn binder and the field silage harvester, either in the amount of corn cut per hour while in operation or in the horse labor required. The harvester saved the work of the man on the corn binder and of the four men who put the bundles of corn on the wagons for the time required to fill the silos. This amounted to approximately 0.75 man hour per ton. To offset this there was a difference in interest, depreciation, repairs, gasoline consumption, and size of tractor required in favor of the cheaper outfit. The value of the extra gasoline, oil, tractor hire, and grease used by the harvester minus the cost of the twine used by the binder was 2.9 c. per ton.

The mower-crusher in hay making, F. J. ZINK (*Agr. Engin.*, 14 (1933), No. 3, pp. 71-73, figs. 7).—The results of tests of the mower-crusher in hay making are reported which were conducted at the Kansas Experiment Station.

The cutting is done by means of a standard mower cutter bar, and the mat formed by the cut swath is elevated and passed between two rollers, which are held in contact with each other by means of springs. The rolls are the same length as the cutter bar. One of the rolls is made of steel, while the other is of steel covered with rubber. After passing between these rolls the hay is dropped to the ground to dry in the usual manner. Power to drive the rolls of the machine is supplied by means of a power take-off shaft from the tractor.

The results indicate that there is apparently a practicable application for the mower-crusher in ordinary haying practice. Under eastern Kansas conditions the rolling process appears to insure a moisture content sufficiently low to permit placing alfalfa hay into storage the same day that it is cut. The rolling process increases the drying rate by stem bleeding and by increased evaporation through the stem fractures. The process provides for a more equal drying rate of leaves and stems, and should prevent leaf losses which are due to the leaves becoming overdry.

Recent developments in stationary spray systems in West Virginia, F. D. CORNELL, JR. (*Agr. Engin.*, 14 (1933), No. 3, pp. 78, 80, figs. 2).—In a contribution from the West Virginia Experiment Station a brief summary is given of recent developments and improvements in stationary spray systems.

Corn borer control with farm machinery, H. N. WORTHLEY and R. U. BLASINGAME (*Pennsylvania Sta. Bul.* 284 (1933), pp. 19, figs. 9).—Studies of corn borer control by the use of machinery are reported, which were conducted in cooperation with the U.S.D.A. Bureau of Agricultural Engineering.

It was less expensive to husk corn from the standing stalks than to cut it, but standing stalks and tall stubble could not be plowed cleanly enough to avoid the hand picking of borer-infested stalks from the surface of plowed ground. Where standing stalks were successfully poled down, while frozen, raked up, and burned, further corn borer control efforts were unnecessary. The cost of these extra operations was nearly balanced by the saving of plowing time in the poled areas. The stalk shaver will doubtless be more generally useful than a drag to break down standing stalks.

It was less expensive to cut corn with a tractor-drawn binder than by hand. A binder hitch causing one tractor wheel to crush a stubble row was an aid to clean plowing. A stationary-knife low-cutting binder performed as well as

a standard binder except in shallow-rooted, drought-stricken corn. It left stubble too short to harbor many borers and saved considerable silage. A husker-shredder saved cost in handling the corn crop and shredded the stalks fine enough to kill borers contained in them. Improved effectiveness of the 14-in. general-purpose walking plow resulted from the addition of a looped chain and wire.

In 7 out of 8 direct comparisons the walking plow equipped with chain and wire gave better coverage of standing stalks than tractor plows with standard equipment. In 10 out of 12 direct comparisons tractor plows equipped with experimental covering devices gave better coverage than the walking plow. However, in ledgy places the walking plow could be operated, while tractor plows had to be lifted from the ground. Width, weight, and beam clearance were important factors in the performance of tractor plows.

Among the covering devices tested, a floating colter, a fixed wide jointer, and a floating trash shield gave sufficient promise to warrant their further development and adaptation to existing makes of tractor plows.

[**Rural electrification investigations at the New Hampshire Station**] (*New Hampshire Sta. Bul. 270 (1933), p. 14*).—The total electrical load used on seven experimental farms is analyzed by W. T. Ackerman.

A study of temperatures in dairy stables, M. A. R. KELLEY (*Agr. Engin., 14 (1933), No. 2, pp. 47-49, fig. 1*).—Studies conducted by the U.S.D.A. Bureau of Agricultural Engineering in cooperation with the Wisconsin Experiment Station are reported, the purpose of which was to study the effect of different stages of stable temperatures and of sudden changes in temperature and the consequent necessity of insulating dairy barns as a factor in temperature maintenance and maximum milk production.

In these tests ventilation was regulated so as to aid in maintaining the desired temperatures and at the same time avoid bad stable air conditions. Heat was available to raise stable temperatures when necessary. On several occasions excessive drafts resulted when an attempt was made to hold stable temperatures lower than outside conditions warranted. As the results of these excessive drafts several cases of pneumonia developed. The same results were obtained both winters.

It was found that if adequate ventilation is maintained the effect of relative humidity upon the cows is not apparent generally under winter stable conditions, and it is not until the temperatures exceed 75° F. and are combined with the high humidities that their results become apparent. The upper limits of 80 percent humidity is prescribed and can be obtained with adequate ventilation, while the relative humidity of the stable will rarely go below 40 and seldom below 50 percent. During the tests a stage of approximately 70 percent was obtained with a small variation above and below. Thus in this prescription is assumed a practical limitation rather than the specific effect on comfort.

Stable temperatures ranging from 40° to 65° in stages of 5° were studied in the test barn. Temperatures in a second barn were permitted to vary with the weather, and these results checked against the records of 90 farm barns with a personal check on 50 of these. Sufficient data were obtained to prescribe a zone of comfort for the dairy cow.

In comparing cows in sections held at from 50° to 55° it was noted that they were more alert, eyes brighter, hair more glossy, and appetite good, while those in sections having temperatures of 60° and 65° stood with ears back, were more restless, had harsh hair, were harder to clean, and had less appetite. At the higher temperature odors were more noticeable, and health inspectors

objected to these. The milkers all preferred the cooler temperatures (50° to 55°).

The heat production of poultry under housing conditions, H. GIESE and F. J. MCCORMICK (*Agr. Engin.*, 14 (1933), No. 3, pp. 67-70, figs. 8).—Studies conducted at the Iowa Experiment Station are reported.

The experiments were conducted with a battery of 10 insulated airtight pens, which were constructed in two tiers of 5 pens each. Each pen was 7 by 5.5 ft. in plan and 3.5 ft. in height. This allowed each bird 3.85 sq. ft. of floor space, as 10 White Leghorn birds were confined in each pen. This battery was entirely enclosed within another building to eliminate the effect of sunlight. Illumination was provided for 12 hours each day by automatically controlled incandescent lamps. The vitamin D deficiency was compensated by feeding cod-liver oil. For the operation periods the air supply was controlled for only 5 of the 10 pens, the others being open to natural ventilation.

The carbon dioxide determinations were made with a Peterson-Palmquist apparatus modified to permit the analysis of air with a very high CO₂ content, such as encountered in these experiments. Air samples were taken through a long glass tube introduced through a small opening in the front of the pen. Relative humidity determinations were made with a psychrometer of special design, such that the wet-and-dry bulb temperatures might be read through a 2-in. diameter opening in the front of the pen without removing any of the air from the pen. A thermometer was hung in each pen from which readings were recorded at 8 a.m. and 4 p.m. daily. The temperature in the surrounding building was also recorded at these hours.

The data secured indicate that heat produced by a chicken varies within wide limits, depending upon environmental conditions. More specifically, the heat production is influenced by thermal characteristic (*C*) of pen or house, and by the outside temperature (*t*), the heat production increasing with an increase in *C* or a decrease in *t*. It is believed that the thermal characteristic may be closely approximated for any given pen or house, and thus the heat which is required of the birds can be estimated for an outside temperature within the range of the studies.

A homemade brick brooder, D. S. WEAVER and C. F. PARRISH (*North Carolina Sta. Agron. Inform. Circ.* 76 (1932), pp. 4, figs. 6).—Practical information is given on the construction of a home-made brick brooder, together with working illustrations.

AGRICULTURAL ECONOMICS

[Investigations in agricultural economics] (*Jour. Farm Econ.*, 14 (1932), No. 4, pp. 679-700, fig. 1).—Notes are included on the following investigations and subjects: The Influence of Spanish and Mexican Land Grants on California Agriculture, by R. H. Allen (pp. 679, 680); Problems in Using County Records in Farm Mortgage Research, by W. G. Murray (pp. 681, 682); Marketing Virginia Farm Flock Eggs on a Graded Basis, by G. H. Ward (pp. 683-685); Changes in Farm Tenancy during Fifty Years, by O. M. Johnson (pp. 685-687); Correct Accounting Principles in Connection with the Payment of Construction Costs on Federal Irrigation Projects, by L. H. Hauter (pp. 687-690); Some Problems in Studying Farm Expenses, by L. F. Garey (pp. 690-692); The California State Water Plan, by G. S. Wehrwein (pp. 692-695); Volume of Farm Mortgage Indebtedness, by D. L. Wickens (pp. 696, 697); and Minnesota Farmers' Response to Price Relationships in the Production of Selected Crops, by R. W. Cox and P. E. Quintus (pp. 697-700).

[Papers presented at the twenty-third annual meeting of the American Farm Economic Association] (*Jour. Farm. Econ.*, 15 (1933), Nos. 1, pp. 1-163, fig. 1; 2, pp. 217-387, figs. 16).—Included are the following papers and discussions thereon presented at the meeting held at Cincinnati, Ohio, December 28-30, 1932: Taxes a Cause of Agricultural Distress, by B. H. Hibbard (pp. 1-13); Farm Mortgage Delinquencies and Foreclosures, by R. M. Green (pp. 14-26); Elements Contributing to Farm-Mortgage Debt Distress, by D. L. Wickens (pp. 27-33); Outlook for Farm Mortgage Debt and Plans for Handling It, by F. F. Hill (pp. 34-56); The Extent, Character, and Future of the New Landward Movement, by P. K. Whelpton (pp. 57-72); Recent Developments in Professional Farm Management in the United States, by D. H. Doane (pp. 73-81); Changes in Organization and in Farm Practices That Have Recently Been Effective on Professionally Managed Mid-West Farms, by W. W. McLaughlin (pp. 82-88); Recent Changes in Organization and Farm Practices, by H. Burr (pp. 89-94); Farm Management, Organization, and Practice, by F. W. Reinoehl (pp. 95-102); Changes in Farm Organization and Practices, by L. H. Woodhouse (pp. 103-110); Changes in Organization and Farm Practices, by E. Baird (pp. 319-330); Short-Term Borrowing Policies of Farmers, by V. B. Hart (pp. 331-348); Measuring the Effect of Supplies on Prices of Farm Products, by L. H. Bean (pp. 349-377); and The Nature of Statistical Supply Curves, by J. M. Cassels (pp. 378-387).

[Investigations in agricultural economics] (*Jour. Farm Econ.*, 15 (1933), No. 1, pp. 164-180).—Notes are included on the following investigations and subjects: The Economic and Historical Background of Farm Tenancy in Delaware, by R. O. Bausman (pp. 164-167); An Analysis of Real Estate Problems of the Minnesota Department of Rural Credits, by A. True (pp. 168-171); Variations in Market Preferences for Hogs, by I. W. Arthur (pp. 171-174); A Comparison of Sale Values of Farm Real Estate and Census Values in Minnesota, by E. C. Johnson (pp. 174-177); Import Quota System in Germany, by H. A. Wadsack (pp. 177-179); and The Electrification of the Village in Czechoslovakia, by S. Borodaewsky (pp. 179, 180).

[Papers on agricultural economics] (*Assoc. South. Agr. Workers Proc.*, 32 (1931), pp. 225-274).—Included are the following papers read at the convention of the Association of Southern Agricultural Workers held at Atlanta, Ga., February 4-6, 1931: The Content of the Agricultural Marketing Course, by J. G. Knapp (pp. 225-233); Inadequacy of Cost-of-Living Figures as Measures of

Standard of Living, by C. E. Allred (pp. 234-242); What Is New in Farm Management Research Methodology? by C. L. Holmes (pp. 242-246); Present Status of the Cooperative Marketing of Cotton, by J. S. Hathcock (pp. 246-259); Methods of Extending Results of Farm Management Research, by V. B. Hart (pp. 260-263); Farm Credit in the South, by D. L. Wickens (pp. 264-268); and Economic and Social Position of the South, by S. H. Hobbs, Jr. (pp. 269-274).

Proceedings of Western Farm Economics Association, 1932 (*West. Farm Econ. Assoc. Proc.*, 6 (1932), pp. [4]+[123], figs. 8).—Included are the following papers presented at the sixth annual conference held at Salt Lake City, Utah, August 9 and 10, 1932: The Problem of Credit to Be Used in Current Agricultural Production, by M. R. Benedict (pp. 1-4); The Farm Mortgage Situation, by R. L. Adams (pp. 5-13) (see below); Present Problems of Re-financing Irrigation Districts, by W. A. Hutchins (pp. 14-22); Agricultural Financing: An Example of an Organization Plan for Agricultural Financing, by L. E. Cline (pp. 23-33); Grazing in Relation to Land Planning, by W. Peterson (pp. 34-41); Agricultural Production and Land Utilization, by A. F. Vass (pp. 42-55); The Interrelation of Farm Management Research with Other Phases of Agricultural Economic Research, by E. A. Starch (pp. 56-59); A Practical Method of Establishing Uniform Units for Cattle Ranch Costs, by C. A. Brennan (pp. 60-64); Farm Management, a synopsis of papers presented and discussed at the conference, by R. L. Adams (pp. 65-68); Farm Relief Measures, by C. C. Conser (pp. 69-72); Economic Planning as Applied to Agriculture, by M. L. Wilson (pp. 73-79); The Possibilities of Economic Planning, by P. A. Eke (pp. 80-85); The Limitations to Social Economic Planning, by G. M. Peterson (pp. 86-97); Limitations to Economic Planning, by E. F. Dummer (pp. 98-100); and Summary and Discussion on Economic Planning, by E. W. Braun (pp. 101-104).

Also included are the resolutions passed by the association suggesting action in improving the position of agriculture in the Western States (pp. 112-114); and a paper on Relation of Watershed to Cultivated Land Planning, by C. L. Forsling, delivered at the Western Outlook Conference held at Salt Lake City, August 10 and 11, 1932 (pp. 118-[123]).

The farm mortgage situation with special reference to the eleven Western States, R. L. ADAMS (*Jour. Farm Econ.*, 14 (1932), No. 4, pp. 605-614).—This article outlines the change in the mortgage situation in the 11 States and the problems arising out of the increase in delinquencies. Comments are made on the policies of foreclosure, of farming lands acquired through foreclosure, and of selling such lands. Some remedies for the situation are suggested.

[Papers presented at the annual meeting of the [British] Agricultural Economics Society] (*Jour. Proc. Agr. Econ. Soc.*, 2 (1932), No. 1, pp. 10-70).—Included are the following papers and discussions thereon presented at the meeting held at Cambridge, England, June 26-29, 1931: The Adjustment of Agriculture to Industrial Rationalisation, by D. H. Macgregor (pp. 10-28); A Farmer's Interpretation of Agricultural Accounts, by W. G. Coates (pp. 29-42); Some Aspects of Meat Distribution and Consumption, by A. Jones (pp. 43-61); and A Contribution to the Study of Occupational and Residential Mobility in the Cotswolds, 1921-1931, by M. A. Abrams (pp. 62-70).

[Investigations in agricultural economics at the Maine Station, 1931-32] (*Maine Sta. Bul.* 363 (1932), pp. 233-246, figs. 6).—Included are results of investigations of prices and price trends of farm products, by C. H. Merchant (pp. 233, 234); of farm taxation, by Merchant and M. S. Parsons (pp. 234-236), including charts showing the relation for the period 1913-31 of prices of farm

products and farm real estate taxes in Maine, and the index numbers of State, county, and municipal taxes on real and personal property; of production and utilization of milk in Maine, by G. F. Dow (pp. 236-241), including charts and tables showing for 1928 the proportions of total production, by counties, sold to larger dealers and smaller retailers and used or made into butter on the farm, the percentages of butterfat sold as milk and as cream when different amounts of butterfat were sold per 100 acres of land, the variation in sales per month of milk and of cream sold to dealers compared with dairymen's sales in New York in 1928 and in Vermont in 1929, and the plant utilization by months of butterfat received by the larger Maine dealers in 1928; of the potato industry in Maine, by W. E. Schrumpf and Merchant (pp. 241-243), giving some preliminary comparisons of labor income, acreage yields, and man labor costs on two groups of farms; and of the factors affecting the quality of Maine potatoes, by Schrumpf (pp. 243-246), including findings as to the percentages of major and minor cuts and bruises due to different causes.

[Investigations in agricultural economics at the New Hampshire Station, 1931-32] (*New Hampshire Sta. Bul.* 270 (1933), pp. 8, 9-11, 13, 14).—Brief reports are made of the following investigations: A study of milk-marketing costs in Laconia, by E. H. Rinear and H. C. Moore; a survey of the town of Dorchester, by H. C. Woodworth, M. F. Abell, et al., showing the utilization of lands, with special reference to timber; a study, in cooperation with the U.S. Department of Agriculture, of the decline, 1930 to 1932, in farm labor incomes on 38 Grafton County dairy farms, by Woodworth, C. W. Harris, Jr., and E. Rauchenstein; a study of roughage production, by Abell, on 328 farms, of which 281 grew silage; fruit farm organization studies, by Woodworth and G. F. Potter; and a study by H. R. Francis of the possibilities of the use of abandoned farm lands for recreational purposes in the town of Sandwich.

[Twentieth annual report of the Agricultural Economics Research Institute, University of Oxford] (*Univ. Oxford, Agr. Econ. Res. Inst. Ann. Rpt.*, 20 (1932), pp. 23, pls. 3).—Included are descriptions of the research, advisory, and educational work done by the institute and a list of its publications during 1932.

Long-term farm credit in a depression, D. L. WICKENS (*Jour. Farm Econ.*, 14 (1932), No. 4, pp. 615-629, figs. 3).—The first part of this article discusses the changes that have taken place in the farm mortgage situation, including tables showing for selected years from 1890 to 1930, usually census years, data as to volume of indebtedness; percentage of owner-operated farms mortgaged, average debt, farm price, and ratio of debt to such farms; percentage mortgage credit is of value of all farms; ratio of mortgage debt to value of mortgaged farms by ratio groups; number of farms owned by Federal land banks and joint-stock land banks (1929, 1930, and 1931); percentage of farms foreclosed of all farms, by years 1926-31; percentage of farms foreclosed during the period 1920-23 and by years 1925-26 to 1929-30; percentage distribution of debt to value of mortgaged farms, January 1932, by geographic divisions; the distribution, 1929, 1930, and 1931, of new loans by methods of payment provided for; and the gross farm income of the United States, by years 1924-31.

The second part discusses the strength and weakness of the various agencies as sources for farm mortgage credit as demonstrated by the normal and abnormal conditions that have existed. The author states that "each of the principal lending institutions providing long-term farm credit has been found to have imperfections for supplying the financing demands of agriculture. In consequence of the severe restrictions on access to outside sources of funds during periods of high rates, the market is either shut off from farmers or it is

forced back in some degree to the simpler but less satisfactory procedure prevailing in pre-war years in which individual borrower and lender undertake to find mutually agreeable amount, term, rate, and other loan conditions. . . .

"The depression has shown more clearly that further progress in farm mortgage finance requires greater reliance upon institutions functionally adapted to the nature of the responsibility, the elimination of arbitrary loaning restrictions which have no basis in economic experience, and general recognition of the necessity of abandoning short-term viewpoints and measures in dealing with a long-term problem. This depression has demonstrated again the futility of legal regulations restricting interest rates to an arbitrary maximum under all conditions; that such provisions during periods of money strain must result in occasional serious interruptions in loan service and the limiting of operations at all times to a group of conditions narrower than economically desirable."

Farm mortgage experience of life insurance companies lending in South Dakota. H. A. STEELE (*South Dakota Sta. Circ. 7 (1932), pp. 40, figs. 15*).—This circular is based on annual statements of life insurance companies lending on farm mortgages in South Dakota filed with the South Dakota Commissioner of Insurance and the Minnesota Department of Insurance, reports of the New York Insurance Department, and Federal Census reports. Tables, charts, and maps are included and discussed showing, among other data, the amount of farm mortgages in South Dakota owned on December 31, 1930, and December 31, 1931, amounts loaned and payments received during the year for each of 36 life insurance companies loaning in the State. Similar data, except for mortgages owned December 31, 1930, are given for 7 other companies.

Forty-three life insurance companies held \$106,075,480 in farm mortgages in the State on December 31, 1931. All real estate owned by 40 companies constituted 3 percent of their total assets. Insurance companies on December 31, 1931, owned 440,095 acres of farm real estate in South Dakota. They reported 4,479 loans with a total principal of \$31,173,800 or 29.4 percent of their total farm mortgage investment on which the principal, interest, or taxes were delinquent for over three months. Farm mortgage loans in the course of foreclosure represented about 8 percent of the total of such loans. The average rate of interest on the delinquent loans was 5.4 percent, and the term for 43 percent of such loans was 5 years. During the year 1931, the insurance companies made 56 outright sales and 24 sale contracts on farm real estate in the State.

Measures taken in foreign countries to relieve agricultural indebtedness, compiled by A. M. HANNAY, M. COULT, and L. CRANS (*U.S. Dept. Agr., Bur. Agr. Econ., Agr. Econ. Bibliog. 42 (1933), pp. [3]+57*).—Included are 127 annotated citations, mostly referring to the present depression, arranged by countries.

Taxation in Maryland with special reference to agriculture, W. P. WALKER and S. H. DEVAULT (*Maryland Sta. Bul. 339 (1932), pp. 261-342, figs. 6*).—The taxable wealth of the State, sources of State and county tax revenues, the administration of assessments, the general property tax and assessment procedure, the distribution and increase of State and county expenditures, expenditures for education and roads, and the bonded indebtedness of the State and counties are described and discussed.

Data were obtained for 1,000 farms in 11 counties regarding assessments for land, buildings, and personal property for the years 1910 to 1927. These are analyzed by periods, size of farms for 1927, type of land and range in assessment for 1917, 1922, and 1927, and by rates of State and county taxes for 1910, 1917, 1922, 1927, and 1932. Other tables show the approximate taxes per farm

and per acre, by years 1911-32, on real estate and personal property. The farm tax burden is discussed with tables showing the relation of taxes per acre, prices of farm products, and value of farm real estate; amounts of different farm products required to pay the general property tax per farm in 1911, 1915, 1920, 1925, and 1931; and the relationship of average farm income and general property taxes, 1929-31, in the Piedmont-Plateau and Eastern Shore areas of the State. Tables and charts show the amounts raised by different State and county taxes in 1932 and the purposes for which these funds were used.

State income taxation, special commodity taxes, gasoline taxes and motor vehicle licenses, and the inheritance and gift tax are discussed, with estimates as to the probable revenues to the State from those not in use at present.

In 1931, general property taxes represented 25 percent of the State tax revenue, licenses and nonbusiness taxes 59 percent, and other taxes 17 percent. About 95 percent of the county revenue was derived from general property taxes. An analysis of 1,546 property sales in 6 counties from 1927 to 1931 showed that the average assessments in the different counties varied from 82 to 110.9 percent of the sale value for the farm properties and from 59.1 to 75.8 percent for the town properties. Assessments on properties selling from 1918 to 1931 for less than \$1,000 averaged 92.1 percent for farm and 76.2 percent for town properties, as compared with 76.4 and 61.2 percent, respectively, for those selling for \$1,000 to \$5,000 and 56.7 and 54.5 percent, respectively, for those selling for over \$5,000.

State expenditures increased over 231 percent from 1915 to 1931, about 29 percent of the increase being due to roads and 25 percent to school costs. The levy of 7 counties increased over 430 percent from 1899 to 1932, of which increase schools accounted for 53 percent, debt for 13 percent, and roads for 10 percent. In 1931, 26 percent of the current State expenditures went for public schools and 22 percent for highways. In the 7 counties studied, about 48 percent was for schools and about 12 percent for roads in 1932. Debt requirements of the counties of the State in 1932 varied from 2.2 to 30.3 percent of the tax levies.

For the 1,000 farms studied, taxes increased from 34 c. per acre in 1911 to 90 c. in 1928, then declined to 84 c. in 1932. Farm taxes in the State in 1932 were 148 percent higher than in 1911-13, while the prices of farm products were 15 percent lower. Taxes absorbed 10 percent of the farm income of 282 Piedmont area farms studied in 1929 and 34 percent in 1931, and 7 percent of the farm income of 267 Eastern Shore farms studied in 1929 and 53 percent in 1931. Of taxes paid by farmers of the State in 1932, about 69 percent were county and 31 percent State taxes.

The following recommendations are made as a result of the study: Continuous assessment should be made by full-time, well-trained, and well-equipped assessors rather than periodical assessments as at present. Farm land and buildings should be assessed as a unit, the proportion of the assessment for buildings used for agricultural purposes being based upon the value they add to the land. A better classification and assessment should be made of woodland in counties using a uniform assessment of such land on the basis of age and condition and with a view to encouraging reforestation. More uniformity should be adopted among the counties as to methods and time of collecting taxes, especially delinquent taxes. A temporary curtailment should be made in the State road building program, and part of the gasoline tax and motor vehicle license fund should be used for maintenance or road debt; county road construction programs should be designed to extend facilities to the greatest

number of rural people and to build lower-cost roads where the traffic does not justify a large investment per mile; county gasoline tax and motor vehicle license revenues should be spent only for road purposes; and license fees for motor trucks should be increased upon the basis of horsepower, weight, and capacity. There should be greater State aid to schools so that counties and cities should not be required to levy more than 40 c. per \$100 valuation for current school expenses, and a sales tax should be applied to luxuries or other indirect taxes used to raise money for State aid to local governmental units for their school program. An income tax law should be enacted to replace in part the local general property tax; the present inheritance tax should be extended to include taxation of transfers to members of the immediate family; and the taxation of transfers of property by gift should be made on the same basis as transfers by inheritance.

A method for the classification of rural lands for assessment in western North Dakota. C. E. KELLOGG (*Jour. Land and Pub. Util. Econ.*, 9 (1933), No. 1, pp. 10-15, figs. 2).—This article points out the requirements of a workable method of classifying rural lands for tax assessment and describes the method being used in McKenzie County, N.Dak., in which the classification for each 40-acre unit is based on a detailed survey of soils, lay of the land, stoniness, drainage ways, etc., and the accumulated experience in the utilization of various types of land.

Changes in the tax system relating especially to forests: Conclusions and recommendations (U.S. Dept. Agr., Forest Serv., *Forest Taxation Inq. Prog. Rpt.* 18 (1933), pp. [61]+60, figs. 2).—This is an advance publication of a portion of the final chapter of a report on forest taxation. Included are the conclusions as to uniform fixed assessment and specific taxes, classification according to the owner's intended use, optional v. compulsory laws, contracts, and separation of land and timber value. Four forest tax plans—the adjusted property, the partial timber exemption, the immature timber exemption, and the yield plan—are described and analyzed as to suitability for equitably meeting the forest situation and as to their effects on public revenues.

The tariff on sugar. L. S. ELLIS (*Freeport, Ill.: Raicleigh Found.*, 1933, pp. 190, figs. 12).—"The object of this monograph is to determine the effectiveness of the tariff on sugar in increasing the price of sugar in the United States, and to measure the costs or benefits to the various groups of consumers and producers in this country." Chapters are included on the world sugar situation, sugar and the United States tariff policy, the sugar industry of continental United States, the sugar market, the effect of the sugar duty on prices, and the costs and benefits of the sugar duty. An introductory note by J. R. Commons, B. H. Hibbard, and W. A. Morton, a discussion of methods of tariff investigation by Morton, a description of the Chadbourne plan submitted to the Cuban planters and the Cuban Government for the stabilization of the sugar industry and the raising of sugar prices, and a discussion of the distribution of sugar among various classes of consumers are also included.

International yearbook of agricultural legislation, 1931 [trans. title] (*Inst. Internat. Agr. [Roma], Ann. Internat. Lég. Agr.*, 21 (1931), pp. LXXXIX+1165).—This volume continues the series previously noted (E.S.R., 67, p. 472).

History of agriculture in the southern United States to 1860. L. C. GRAY and E. K. THOMPSON (*Carnegie Inst. Wash. Pub.* 430 (1933), vols. 1-2, pp. XIX+IX+1086, figs. 12).—The several parts of this history, which is a companion study to that for the northern United States (E.S.R., 54, p. 88), deal with agricultural beginnings and geographic expansion, agricultural industries

in the colonial period, institutional development in the colonial period, economic evolution in the South, the development of national economy, agricultural industries and husbandry in the post colonial period, and geographic expansion and regional development. Its organization is described by the author as follows:

"Except for certain chapters dealing with broad tendencies which manifested themselves throughout the ante bellum period, it will be found that there are three primary chronological subdivisions—the colonial period; a period of transition from colonial to national economy, extending from the close of the Revolutionary War to about the time of Whitney's invention of the cotton gin; and the remaining period up to the Civil War. Each of these chronological divisions is subdivided topically, and each topic is usually considered chronologically and to some extent geographically. Inasmuch as the topical treatment fails to provide a synthetic picture of agricultural development in the various important regions, at the risk of a seeming lack of unity I have introduced certain chapters sketching in broad strokes the course of agricultural expansion by regions. For the purpose of avoiding unnecessary repetition of details, already treated by topics, I have made extensive use of cross references, and while the regional chapters give the broader lines of development and the distinctive characteristics by regions, a more complete regional picture can be gained only by supplementary reference to the topical chapters."

An extensive bibliography (pp. 945-1016) and statistical tables and notes (pp. 1019-1043) are included.

The introductory note is by H. C. Taylor.

The farm and the nation, E. J. RUSSELL (London: George Allen & Unwin, 1933, pp. 240, fls. 9).—The factors involved in developing the agriculture of the British Empire "for the purpose of preserving it and using it for increasing the national wealth and opening up work on the land for some of the growing army of unemployed" are discussed in chapters on *The Nation's Food: From Whence Does It Come?* *The Ups and Downs of British Farming*; *Our Farming Land; How We Now Use It; The Result of Our Agricultural Efforts; The Empire as a Source of Food; The Empire's Contribution to Our Food Supply: Could It Be Increased?* *Some of the Farmer's Difficulties; How Can We Use Our Land to Better Purpose?* and *Can the Country Districts Absorb the Displaced Men?*

[*Proceedings of the Council of Agriculture for England*] (*Jour. Min. Agr. [Gt. Brit.]*, 39 (1933), No. 10, pp. 930-951).—Included are the reports of the standing committees on the subjects of the interim and final reports of the Central Landowners' Association on agricultural policy and of the purity of the milk supply, on the report of the Reorganization Commission for Pigs and Pig Products, and on the subject of the Dutch auction system, together with the discussions on these reports and other subjects.

Imperial Economic Conference, 1932: Report of the Conference (*Ottawa: Govt., 1932, pp. 159; Sup. vol., pp. 82*).—These two volumes include the report of the Conference held at Ottawa, July 21 to August 20, 1932.

The first volume includes a list of the personnel; the reports of the committees and the subcommittees on the promotion of trade within the Commonwealth, customs administration, commercial relations with foreign countries, monetary and financial questions, and methods of economic cooperation, and the Conference conclusions on each subject, together with the concluding resolutions of the Conference and the statements of the several delegates. The second or supplementary volume includes the texts of the trade agreements

concluded during the Conference between the United Kingdom and Australia, Union of South Africa, New Zealand, India, Newfoundland, Southern Rhodesia, and Canada; between Canada and Irish Free State, Union of South Africa, and Southern Rhodesia; and between the Union of South Africa and Irish Free State.

Imperial Economic Conference at Ottawa, 1932: Summary of proceedings and copies of trade agreements [and appendices] (*London: Govt., 1932, pp. 95: App., pp. 205*).—The first volume summarizes the conclusions in the report noted above and includes the texts of the agreements between the United Kingdom and the several dominions. The second volume presents the same information as given in volume 1 noted above.

Ottawa Conference Number (*Farming in So. Africa, 8 (1933), No. 83, pp. 39-90, figs. 18*).—Included is an article entitled *The Ottawa Conference and Our Agricultural Export Trade*, by P. R. Viljoen (pp. 39-48), discussing the Imperial Economic Conference and the agricultural export trade of the Union of South Africa, including farming conditions in overseas countries, the Union's overseas markets and trade with the United Kingdom and Canada, British preferences, and the Empire trade and the Conference. Other articles on the Union's agricultural exports and departmental organization and work are also included as follows: *Our Livestock and Meat Industry*, by C. H. Neveling and D. J. Schutte (pp. 49-51, 88); *The Dairy Industry in the Union*, by E. G. Hardy (pp. 52-55); *Export of Fish and Fish Products from the Union of South Africa* (pp. 56, 82); *The South African Export Poultry Industry*, by J. J. Jordaan, A. J. Beyleveld, and C. H. Spamer (pp. 57, 58, 62); *The Mohair Industry*, by F. J. du Toit and H. M. Stoker (pp. 59, 62); *The Wool Industry in South Africa*, by G. J. Schuurman, H. M. Stoker, and A. F. du Plessis (pp. 60-62); *The Union's Hide and Skin Industry*, by C. H. Neveling (pp. 63, 64); *The South African Export Fruit Industry*, by F. G. Anderssen, A. J. Beyleveld, et al. (pp. 65-76, 82); *The Future of Our Maize Industry*, by S. J. de Swardt and M. G. Stahl (pp. 77-79); *Production and Utilization of South African Peanuts*, by F. M. du Toit (pp. 80-82); *Development of the Wattle Bark Industry in South Africa*; *Marketing Prospects for the Future*, by W. E. Watt and A. J. Beyleveld (pp. 83, 84, 86); *Tobacco Production in the Union*, by P. Koch and W. J. Pretorius (pp. 85, 86); *Development of a Meat Export Trade*, by P. R. Viljoen (pp. 87, 88); and *Quality Requirements in the Export of Beef*, by D. J. Schutte (pp. 89, 90).

Diminishing returns in view of progress in agricultural production, T. W. SCHULTZ (*Jour. Farm Econ., 14 (1932), No. 4, pp. 640-649*).—This contribution from the Iowa Experiment Station presents the results of a study of the Iowa crop production 1880-1930, comments upon certain aspects of the phenomenon of diminishing returns, and discusses whether the experience of agriculture tends to invalidate Marshall's interpretation of the law of diminishing returns.

Voluntary allotment: Planned production in American agriculture, E. S. MEAD and B. OSTROLENK (*Philadelphia: Univ. Penn. Press; London: Humphrey Milford, Oxford Univ. Press, 1933, pp. V+147*).—"We propose now to tell the sequel to the story told in Harvey Baum [*E.S.R.*, 60, p. 585], to describe in some detail the agricultural crash in which the agricultural depression has culminated; to outline the pattern of the rural life of the future, provided events are allowed to work themselves out without control, remedy, or effective farm revolt; and finally to discuss the plan to use the arm of the Federal Government to stabilize agriculture, the largest American industry, a plan which may furnish a pattern for the realization of planned production." The

several chapter headings are: Ole Swanson—a typical American farmer, the farmer in 1932, the profitless decade in American agriculture, increasing production and decreasing demand, the operation of "natural economic law" in American agriculture, stabilization by farm attrition versus controlled production, the repeal of the law of supply and demand, the voluntary allotment plan, how the plan will work, and farm relief the way out of the depression.

Local land-utilization studies in relation to problems of rural economic organization, C. F. CLAYTON (*Jour. Farm Econ.*, 14 (1932), No. 4, pp. 662-678).—"The special object of this paper is to consider the scope and purpose of the type of local land-utilization study which has as its central problem the determination of an appropriate pattern of rural economic organization for an established and organized local population group." The several premises and points of view from which studies of rural economic organization have been or may be undertaken, the nature of the findings of such studies, and the place of land-utilization studies in the studies of rural economic organization are discussed.

Four hundred million acres: The public lands and resources, C. E. WINTER (*Casper, Wyo.: Overland Pub. Co., 1932, pp. 352, pls. 16, figs. 4*).—This volume presents information regarding public lands in the United States, past and present United States land policies, and proposed future policies. "As a whole it supports the cession of all the remaining lands and their resources, excepting the national parks, by the Federal Government to the States in which they are situated."

The influence of type of production and size of farm on Illinois farm expenses, 1926-1928, R. C. ROSS (*Abstr. Thesis, Univ. Ill., Urbana, 1931, pp. [19]*).—This is an abstract of a doctorate thesis. The study was based on records kept by the operators of 475 Illinois farms for the period 1926-28 as part of the extension work of the university. Its purpose was "to determine for farms of various sizes and for different types of production (1) the amounts and kinds of cash expense incurred in carrying on the business; (2) the nature and amounts of expense other than cash outlays; (3) the investment of new capital in the business, and the extent to which such expenditures maintained or increased the value of the productive plant; and (4) the relationships of expenses and capital expenditures to the size and nature of the farming business, as a basis for setting up working standards for budgeting purposes."

Proceedings of the New Jersey Land Use Conference (*New Jersey Stat. Bul. 552 (1933), pp. 78, figs. 2*).—Included are a list of the sponsoring committees and the following papers presented at the conference held at New Brunswick, N.J., December 21, 1932: Address of Welcome, by R. C. Clothier (pp. 9, 10); The Purpose and Scope of the Land Use Conference, by J. G. Lipman (pp. 10-13); Land Use Policies and Programs in the United States, by A. R. Mann (pp. 13-22); Aspects of a State Program of Land Utilization, by L. C. Gray (pp. 22-30); Land Use and Soil Erosion, by H. H. Bennett (pp. 31-47); The Land Resources of New Jersey, by L. L. Lee (pp. 47-57); Land Use in New Jersey, by J. K. Powell (pp. 57, 58); Can the Utilization of Idle Land Be Made a Factor in the Reduction of Delinquency? by C. Derrick (pp. 58-64); Financing Home Ownership, by F. G. Stickel, Jr. (pp. 64-72); and Forestry and Parks in Relation to Land Use, by C. P. Wilber (pp. 72-76).

Cost of irrigation water in California, H. F. BLANEY and M. R. HUBERTY (*Calif. Dept. Pub. Works, Div. Water Resources Bul. 36 (1930), pp. 146, figs. 14*).—This is a revision, extension, and enlargement of the report previously noted (*E.S.R.*, 53, p. 587) and presents the results of a study covering several years, the data for 1929 being given in the greatest detail. The variations

in annual cost of irrigation water in 1929 under public utilities, mutual water companies, and irrigation districts are summarized in groups comprising various crops and systems furnishing gravity water only and pumped water only in tables showing among other things the acreage of different crops irrigated, factors in annual cost of water, and the annual cost of water. A chapter discusses the general factors entering into the cost of pumping. An appendix includes similar tables for 1922 reprinted from the earlier bulletin.

Permissible annual charges for irrigation water in upper San Joaquin Valley. F. ADAMS and M. R. HUBERTY (*Calif. Dept. Pub. Works, Div. Water Resources Bul. 34* (1930), pp. 89, figs. 7).—The results are presented of an investigation made in cooperation with the College of Agriculture of the University of California to determine how much the landowners of the area can afford to pay for irrigation water brought into the area under the proposed State plan of water conservation. "The detailed procedure followed in the investigation has been (1) to ascertain the costs of producing and harvesting the principal crops grown in the upper San Joaquin Valley, without including interest on the average investment or a charge for irrigation water; (2) to estimate the farm income on the basis of probable yields and prices; (3) to compute interest on the average investment at 6 percent per annum; and (4) from the foregoing to ascertain the margin remaining, after covering the costs of producing and harvesting the crop, together with interest at 6 percent per annum. It has been assumed that this amount will be available for payments for irrigation water and additional profits over interest." Complete data with charts "from which the amount available above the costs of producing and harvesting the crop and interest at 6 percent can be readily computed" are given for oranges, deciduous fruits, grapes, and cotton. Less complete data are given for alfalfa, grain, and miscellaneous crops.

The report of a study by C. V. Givan and J. E. Christiansen of the cost of water to irrigators in the upper San Joaquin Valley (pp. 81-89) includes an analysis of data regarding the costs of gravity and pumped water, costs for different crops, and costs under different types of organizations.

The world wheat situation, 1931-32: A review of the crop year. M. K. BENNETT ET AL. (*Wheat Studies, Food Res. Inst. [Stanford Univ.], 9* (1932), No. 3, pp. [1]+63-136, figs. 28).—This is a continuation of the series previously noted (E.S.R., 67, p. 182). The year 1931 ended with another large crop in prospect, the fourth in succession and the third of severe economic recession. World wheat prices in gold fluctuated on the lowest level in modern times.

Low prices stimulated the food use of wheat in China and feed use in North America and a few free-trade European countries. Larger fractions of North American surpluses were retained domestically than ever before. World stocks were reduced only about 40,000,000 bu. during the year, and at the close were more than 50 percent above normal. United States wheat made up nearly 45 percent of the world carry-over, a record proportion.

Other subjects discussed are governmental operations and regulations, wheat prices, and international trade and consumption. Some 36 tables are carried in the appendix.

Survey of the wheat situation, April to July 1932 and August to November 1932. M. K. BENNETT, H. C. FARNSWORTH, ET AL. (*Wheat Studies, Food Res. Inst. [Stanford Univ.], 8* (1932), No. 10, pp. [1]+469-502, figs. 6; 9 (1933), No. 4, pp. [1]+137-166, figs. 6).—These studies are a continuation of the series previously noted (E.S.R., 68, p. 113).

In the April-July 1932 period international shipments of wheat dropped from a peak in May to very low levels in July. General pessimism and favor-

able crop news preceded a sharp drop in wheat prices in early June. By July prices had recovered somewhat but remained distinctly low. The crop year 1932-33 was viewed as one of burdensome wheat surplus. Price movements would be influenced by pressure of exports from other producing countries and the course of business.

In the August-November 1932 period, reported in No. 4, international trade in wheat was the smallest in a decade. Despite heavy supplies, United States exports were the smallest in years. International wheat prices declined in the September-November period, and new record low prices were registered in all future markets in November-December, though Chicago prices remained above export parity.

The wheat outlook, as viewed in mid-December, is also discussed. Statistical tables are included in appendixes to the two numbers.

Estimation of end-year world wheat stocks from 1922. M. K. BENNETT (*Wheat Studies, Food Res. Inst. [Stanford Univ.]*, 9 (1933), No. 5, pp. [1]+167-186).—"The purposes of this study are to present estimates of 'world' wheat stocks ex-Russia at the end of each of the 11 crop years beginning with 1921-22, including estimates for as many positions and countries as the data justify; and to describe the methods of estimation."

Price relations between July and September wheat futures at Chicago since 1885. H. WORKING (*Wheat Studies, Food Res. Inst. [Stanford Univ.]*, 9 (1933), No. 6, pp. [1]+187-238, figs. 9).—Some conclusions drawn concerning these relations are as follows:

"Given an accurate appraisal of the domestic supply position, the price spread in June may usually be predicted with great accuracy. Substantial disparity between the actual spread in June and that to be expected from the supply statistics has occurred in eight years since 1896. . . . Existence of such a disparity gives prima facie evidence of abnormal speculative market conditions. Changes in the spread tend to occur in response to influences specifically related to the spread, and not in response to general price influences. . . . The July-September price spread is subject to conspicuous and reliably predictable seasonal changes."

Price statistics for the years studied are included in the appendix.

Trends in the apple industry. C. C. HAMPSON (*Washington Col. Sta. Bul.* 277 (1933), pp. 108, figs. 32).—This study was made "to determine the prospects in the apple industry, considering quantity of production, recent plantings and market possibilities, and particularly to estimate the future situation of apple growers of Washington." Tables and charts are included and discussed showing the annual changes and trends of export prices of apples, 1789-1930, of prices of apples in the United States, 1910-30, of Baldwin apples in Boston, 1889-1930, and prices to Wenatchee-Okanogan growers, 1912-30; apple production, total 1889-1931 and commercial 1916-31, and car-lot shipments, 1916-31, in the United States, the box States, and the barrel States; the number of trees, bearing and nonbearing, 1910, 1920, 1925, and 1930; the percentage of trees, total and by varieties, in four age groups in 1928, and the average yield per tree during different periods, 1907 to 1931, in the United States, the box States, and the barrel States; and the trends in production, 1909-31, of different competing fruits. Similar data are analyzed in detail for Washington and the several districts and subdistricts of the State.

From 1911-15 to 1927-31 total production changed as follows: Box States increased 34,000,000 bu., barrel States decreased 88,000,000 bu., and Washington increased 24,779,000 bu. The average commercial production from 1916-20 to 1927-31 changed as follows: Box States increased 16,702,000 bu., barrel

States decreased 1,807,000 bu., and Washington increased 11,132,000 bu. Average car-lot shipments, 1916-20 to 1926-30, increased 25,490 in the box States, 10,127 in the barrel States, and 18,006 in Washington. The average yield per tree, 1907-11 to 1927-31, increased from 1.25 to 4.21 bu. in the box States, from 1 to 1.41 bu. in the barrel States, and from 1.3 to 6.1 bu. in Washington. The number of bearing trees in the period 1920-30 decreased 7,836,000 in the box States, 18,630,000 in the barrel States, and 2,770,000 in Washington. The number of nonbearing trees from 1920 to 1930 decreased 1,048,000 in the box States and 7,696,000 in the barrel States and increased 192,000 in Washington.

During the period 1927-31 Washington produced about 19 percent of the total production, 28.5 percent of the commercial crop, and 32.8 percent of the car-lot shipments of apples in the United States. About 86 percent of the State's total crop was marketed as fresh fruit, as compared with 59 percent in all other States. The number of bearing trees in 1930 was 73 percent more than in 1910, but approximately 2,800,000, or 35 percent, less than in 1920. During the next 5 years in Washington more trees will reach the commercial bearing age annually than during recent years, but the increase in yield will be retarded by the fact that approximately three fourths of the trees have either completed or will soon complete their early bearing period.

As to the next few years, the number of plantings, age of trees, etc., indicate that the production of Winesap apples in Washington will increase less rapidly than heretofore and that later production may fail to increase; that the production of Delicious apples will probably continue to increase at about the same rate as heretofore, but that at least part of the premium paid for this variety will disappear due to both the quality and the quantity produced in the barrel States; that the production of Jonathans will become relatively less important due to the decrease in the number of trees in Washington and the material increase in production in the barrel States; that the production of Rome Beauty apples will not increase rapidly in Washington, but there will be a heavier production in the barrel States; and that there will be no appreciable increase in the production of Yellow Newtown apples in Washington.

The present trends indicate shifts in Washington production from lower-priced varieties to the Delicious variety, and a shift in production from the lower Yakima Valley to the upper Yakima Valley.

Economic studies of dairy farming in New York.—X, 141 farms in the Tully-Homer area, crop year 1926, E. G. MISNER (*New York Cornell Sta. Bul.* 551 (1933), pp. 105, figs. 36).—Data for the year ended February 28, 1927, were gathered by the survey method in part of the area studied for 1921 (E.S.R., 52, p. 589). The types of farming in the area, climate, soils and topography, transportation facilities, markets, etc., are described. The data regarding farm capital, receipts from crops, livestock, livestock products, and other sources, expenses and labor income are analyzed and discussed. The price premiums for milk and the successful farms are described and discussed, and some comparisons are made between the same farms in 1921 and 1926.

Size of business was one of the most important factors affecting labor income. Productive-man-work units, number of cows, acres in crops, and man equivalent were the best measures of this factor. On dairy farms, tons of milk per man was the most important measure of efficiency, about 45 tons being needed on grade A milk farms to realize a \$2,500 labor income. Farms with less than 30 tons per man averaged very low labor incomes. Productive-man-work units accomplished per man was a good measure of the efficiency of labor, at least 250 work units per man being necessary for a high income.

Crop acres per man and animal units per man did not show as high a relationship. Rates of turn-over of capital ranked next below efficiency in man labor as a factor affecting labor income.

Farms producing less than 6,000 lb. of milk per cow showed lower labor incomes, while those with 7,000 lb. or more had an income of \$1,973. Farms with a crop index for feed crops of 160 percent or more of the State average made high labor incomes. The crop index of potatoes, cabbage, peas, and other cash crops did not bear so close a relationship to income.

Although the leading enterprise of the section is market milk, the success of the farm business depends to a large extent on combining other enterprises with dairying. Intensively stocked farms were more profitable than those with a large area per animal unit. The farms with a small percentage of the cattle units in heifers were the more profitable.

The average labor income on the farms selling grade A milk was \$1,216, and that on grade B farms \$429. Of the average receipts, 67 percent was from milk sold, 10 percent each from livestock and crops sold, 8 percent from increase in inventory, and 5 percent from miscellaneous sources. Of the current expenses, 27.4 percent was for labor other than that of the operator, 33.5 percent for feeds, 6.1 percent for taxes, 7.1 percent for machinery, including purchases and repairs, and the balance for miscellaneous items.

Part-time farming: A brief list of recent references, compiled by E. M. COLVIN (*U.S. Dept. Agr., Bur. Agr. Econ., Agr. Econ. Bibliog.* 43 (1933), pp. 20+[3]).—Included are 56 annotated citations from pamphlets, periodical articles, congressional hearings, and editorials.

Agricultural marketing, B. N. BHARGAVA (*Univ. Lucknow, Studies Econ. and Sociol.* No. 5 (1930), pp. [2]+XIII+109).—The marketing of grain in the rural areas of India is discussed in chapters on the cultivator as a trader, the chain of middlemen, speculation, storage, periodical markets, transport, and some main defects and suggestions.

Roadside marketing of agricultural products by Ohio farmers, C. W. HAUCK and H. M. HERSCHLER (*Ohio Sta. Bul.* 521 (1933), pp. 37, figs. 5).—This bulletin is based on data obtained regarding markets operated in 1931 and 1932. In analyzing the data the markets were grouped into four classes on the basis chiefly of permanency of buildings, and into three classes on the basis of type of road on which located. The number and types of markets and their location as regards type of road and distance from the nearest municipality, the products sold, volume of sales, overhead and operating costs, period of operation, prices charged, and patronage are discussed. Included also is a study of the sources of food supply of 198 wealthy, 1,146 medium income, and 400 poor Columbus families, and the purchases at roadside markets by Columbus families. The possibilities of cooperative roadside marketing are discussed.

The home market for North Carolina cotton, J. G. KNAPP (*North Carolina Sta. Bul.* 284 (1933), pp. 58, figs. 11).—This bulletin is based chiefly on the reports of the Federal Departments of Agriculture and Commerce dealing with cotton production, consumption, and grade and staple estimates, and reports on mill requirements secured from 115 North Carolina mills for the years 1927-29, 121 mills for 1930, and 94 mills for 1931.

Tables and charts are included and discussed showing the consumption of cotton, by years 1919-20 to 1930-31, inclusive, in the 5 leading cotton-manufacturing States, and the percentage distribution, by staple lengths, 1928-29 to 1931-32; and the sources of supply and the percentage distribution of cotton used by North Carolina mills, by staple lengths, 1926-27 to 1930-31, and by grades, 1929-30 and 1930-31. Other charts and tables show the relations between the

amounts of cotton of different staple lengths and grades produced and consumed in the State and in each of the 4 geographic regions, and the sources of out-of-State cotton consumed in each region. The importance of quality of cotton in yarn manufacture, the suggestions of mills as to how the cotton producers of the State can best serve the mill needs, and the accomplishments in the State in improving grade and staple lengths are discussed.

Appendixes include discussions of the method used in estimating consumption by grade and staple length; the changes in staple length consumption by 41 mills from 1928-27 to 1930-31; the distribution of consumption, 1927-31, of different staple lengths; the changes, 1910-11 to 1930-31, in the production, consumption and exportation of cotton; and the percentage distribution of North Carolina cotton production, 1928-29 to 1931-32, by staple length, grade, color, and tenderability.

The annual averages for 1927-31 were North Carolina production, 912,660 bales; North Carolina consumption, 1,505,575 bales; and North Carolina consumption of North Carolina cotton, 498,096 bales. The out-of-State movement of North Carolina cotton, although rapidly diminishing, can be accounted for largely by the shortness of staple length. No North Carolina cotton is moving out of the State because of lowness of grade, as more cotton of the lower grades is consumed than is normally produced. Physical separation of the producing and consuming areas of the State and the quality of cotton produced and consumed in the different areas are important factors affecting the consumption of North Carolina cotton in the State. The mills of the State suggest that the producers of the State can best meet the needs by increasing staple length, by developing greater uniformity of staple and grade, and by improving grade through better handling practices.

Financial operations of Ohio farmer owned elevators during the fiscal year 1931-32. B. A. WALLACE (*Ohio State Univ., Dept. Rural Econ. Mimeogr. Bul. 50 (1932), pp. 17, fig. 1*).—This is a continuation of the study previously noted (E.S.R., 66, p. 585). It is based on the analysis of the principal balance sheet and income and expense items of 147 companies operating 178 plants, detailed analysis of expense items, commodity sales, and margins of 45 companies, and the accounts receivable of 17 companies for the period January 1928 to December 1931. Comparisons are made with the three preceding years.

The burden of increased costs of distribution. G. SHEPHERD (*Jour. Farm Econ., 14 (1932), No. 4, pp. 650-661, figs. 3*).—Using Iowa as the source of supply and New York City as the source of demand and assuming a \$1 per 100 lb. increase in shipping charges, analysis is made of the effects on supply, demand, and farm and consumer prices of hogs considering (1) the slope of the demand and supply curves and (2) the ease with which these curves shift as a whole.

In summing up his findings, the author states that "the effects of a general increase in distributive costs, or of a business depression, or of a falling general price level are similar. They all cause a downward shift in the demand schedule for agricultural products. The demand curve cuts the supply curve at a lower point. But instead of production decreasing and the burden of the change being divided between producer and consumer, the producer, having already made his commitments in his plant as a going concern, continues to produce as large quantities as before, though at a lower price level; the supply curve shifts downward and the producer bears the whole burden himself. . . .

"The total demand for agricultural products is increasing at a very much slower pace now than before the war. Probably by the time another 10 or 20 years have elapsed it will have ceased to increase at all. Agriculture is losing a large part of its powers of recuperation. The burden of increased costs of

distribution (mostly the result of higher freight rates and higher labor wage scales) or of a business depression, or of a falling general price level, falls chiefly on the producer now the same as it did before the war. But whereas a generation or two ago the steady increase in the demand for agricultural products helped him to roll the burden off with the passage of time, nowadays the load settles on his shoulders more permanently; he must struggle with it unaided until such time as the property is passed on to a new owner on a new value basis."

Competition in the American tobacco industry, 1911-1932, R. COX (*Thesis, Columbia Univ., New York, 1933, pp. 373, pls. 4*).—This is "a study of the effects of the partition of the American Tobacco Company by the United States Supreme Court."² The several chapters analyze and discuss the partition of the company, the growth of the tobacco industry since the partition, evidences of competition in the distribution of business among manufacturers, competitive influences affecting the scale of production, competitive influences affecting integration, competition in the purchase of leaf tobacco, evidences of collusion in leaf purchases, price competition among manufacturers in the sale of tobacco products, nonprice competition among manufacturers in the sale of tobacco products, competition among distributors of tobacco products, effects of competition on the successor company earnings, and financial control of the successor companies. The final chapter contains the conclusions of the author. A description and discussion of the United Cigar Stores Company (pp. 325-360) is also included.

The wholesale poultry business in San Francisco, E. T. GREYER (*Jour. Farm Econ., 14 (1932), No. 4, pp. 630-639*).—The organization and trends in the business from 1900 to 1930 are described. The changes brought about by the formation of a holding and operating company in 1928, and the formation of two farmers' cooperative companies, one in 1926 and the other in 1929, are discussed.

Report of the reorganisation commission for milk, E. GRIGG ET AL. ([*Gt. Brit.*] *Min. Agr. and Fisheries, Econ. Scr. 38 (1933), pp. 228*).—This is the report of the commission appointed in April 1932 under the Agricultural Marketing Act, 1931, to prepare "a scheme or schemes (applicable in England and Wales) for regulating the marketing of milk." The several chapters cover milk marketing in England and Wales since 1922, production and the position of the producer, distribution and the position of the distributor, consumption and the interests of the consumer, manufacture and imports, the law as it affects milk, costs and profits of distribution, objects and the structure of reorganization, grades and quality, price policy—schemes considered, price policy for milk for liquid consumption, price policy for manufacturing milk, distribution of powers, development of manufacture and recommendations regarding duties on imported milk products, and cooperation with Scotland and Northern Ireland. Other chapters summarize the main conclusions and recommendations and the concluding observations of the commission.

The United States export and import trade in dairy products, K. H. McDONALD (*Michigan Sta. Tech. Bul. 131 (1933), pp. 37, figs. 6*).—This bulletin, which gives special consideration to the tariff on dairy products, includes and discusses tables and charts showing the production of dairy products, 1925-28, of the principal exporting and importing countries; the exports and imports of the United States of fresh milk and cream, by 5-year periods 1891-1920, and by years 1921-30, and of condensed, evaporated, and powdered milk, by years 1910-31; the destination of United States exports of condensed and

² 221 U.S. 106; also as U.S. Senate, 62. Cong., 1. Sess., Doc. 40 (1911).

evaporated milk, 1926-29; the exports and imports of the United States of cheese and butter, by 5-year periods 1871-1920, and by years 1921-31; the destination of such exports, 1926-29; the United States imports for consumption, by years 1910-31, of cream, fresh milk, cheese and cheese substitutes, butter, and casein; and comparisons of the costs of production in the United States and the costs of production, including transportation to border plants, normal principal markets, or New York City, of fluid milk and cream in Canada, cheese in Switzerland, butter in Denmark, and casein in Argentina. Tables give the rates of duty on dairy products under different United States tariff acts, 1789 to 1930. The effects of the different acts on imports are discussed.

The overseas trade of the United Kingdom, 1924-31, H. W. MACROSTY (*Jour. Roy. Statis. Soc., n. ser., 95 (1932), No. 4, pp. 607-657*).—This is a paper read before the Royal Statistical Society, May 24, 1932, with discussions thereon. It surveys the British overseas trade as a whole and in its chief categories of food, drink, and tobacco, raw materials, and manufactured goods; examines chief groups of commodities within the main classes, with special reference to the state of the export trade in 1929 and 1931; and gives some notes on the chief groups of commodities with a view to indicating the main characteristics of each trade.

Crops and Markets, [April 1933] (U.S. Dept. Agr., Crops and Markets, 10 (1933), No. 4, pp. 113-152, figs. 3).—Included, besides reports, summaries, tables, charts, etc., of the usual types, are brief discussions of the changes in farm population during 1932 and of the farm products price situation and an article on income from farm production in the United States, 1932, analyzing the income as a whole and the gross and cash incomes, by States, and making comparisons with other years, principally 1924-31 and 1920-31.

International yearbook of agricultural statistics, 1931-32 (Internatl. Inst. Agr. [Roma], Internatl. Yearbook Agr. Statis., 1931-32, pp. XXXIX+782).—This is a continuation of the series previously noted (E.S.R., 66, p. 885). The following changes have been made from earlier volumes: (1) The period used as the basis of comparison has been changed from the average 1909-13, or in certain cases 1913 to the average for the quinquennium, or in some cases the year, immediately preceding the series; (2) the tables on prices have been enlarged by the addition of quotations for a number of products and markets; (3) comparative tables have been added giving for all products and markets concerned the equivalents in gold francs per quintal of the original quotations; (4) tables of stocks and further tables relative to the distribution of agricultural holdings according to size and mode of tenure have been added; (5) tables relating to chemical fertilizers have been revised; and (6) the forest statistics have been omitted and are to be published in a separate series.

RURAL SOCIOLOGY

Population trends in the United States, W. S. THOMPSON and P. K. WHELPTON (*New York and London: McGraw-Hill Book Co., 1933, pp. X+415, figs. 36*).—This is "one of a series of monographs published under the direction of the President's Research Committee on Social Trends, embodying scientific information assembled for the use of the Committee in the preparation of its report entitled *Recent Social Trends in the United States*." The several chapters deal with the growth of population in the United States, the distribution of the population, the national origins of the white population, the age composition of the population, sex composition, marital condition, deaths and death rates, births and birth rates, population growth from immigration and natural increase, probable trends and consequences of future growth, and population policy.

AGRICULTURAL AND HOME ECONOMICS EDUCATION

Effectiveness of vocational education in agriculture, F. W. LATHROP (*Fed. Bd. Vocat. Ed. Bul. 82, rev. (1933), pp. VII+19, figs. 8*).—This study of the value of vocational instruction in agriculture in secondary schools as indicated by the occupational distribution of former students is a revision of the bulletin previously noted (*E.S.R.*, 60, p. 890). The occupations of the 1917–22 and the 1922–27 groups have been rechecked after another 5-year period, and analysis is made of a random selection of 6,279 students in 47 States who left school in the period 1927–32. Charts are included and discussed showing the occupational and farming tenure distribution of each group at the end of each 5-year period, 1917–32. Other tables and charts show the percentage of students leaving school each year, 1920–31, who are now farming, the relation of effect of length of course of training to percentage of students farming, the average number of years of vocational training received by the students reporting for each period, and the percentage of such students who were high school graduates.

Some of the findings were as follows: The percentage of vocational agriculture students going into farming has increased and that entering colleges has decreased. There has been practically no change in the percentage of students with recent training who have taken over entire responsibility for operating farms, but there has been some increase in the percentage of renters. The number of students farming has tended to decrease, due largely to partners and laborers shifting into nonagricultural occupations. The number of owners in both the 1917–22 and the 1927–32 groups had practically doubled by 1932, and there had been a general movement upward in the farming occupation scale on the part of former students. The percentage of students farming was higher for recent than for earlier graduates. Students with two or more years of vocational training are more likely to remain on the farm than those with only one year of training. Recent students on an average have received a somewhat longer training than earlier students, and a larger percentage of them are high school graduates.

The meaning of the findings to State and local programs of vocational education in agriculture is discussed.

A statistical survey of home economics in the public schools of the United States, 1931–1932 (*New York: Metrop. Life Ins. Co., [1932], pp. 24*).—The data, which cover 80,644 elementary and high schools with an enrollment of 5,475,772 girls, were obtained through questionnaires returned by county and city superintendents of schools. In general, the tables included show for city and county high and elementary schools, by States, city high and elementary schools, by size of city, and city and county elementary schools, by grades, the number of schools reporting, number offering home economics courses, total enrollment of girls, and the number of girls enrolled in home economics courses.

Readings in marketing, F. E. CLARK (*New York: Macmillan Co., 1933, rev. ed., pp. XX+798, pls. 2, figs. 32*).—This is a revised edition of the text previously noted (*E.S.R.*, 53, p. 694). The readings are grouped under the following headings: Introduction, marketing functions, marketing farm products, wholesaling farm products, middlemen of the agricultural wholesale market, marketing raw materials, marketing manufactured products, wholesale middlemen of the manufacturers' market, direct marketing of manufactured products, retail distribution, large-scale retail establishments, recent developments in retailing, cooperative marketing, physical supply, market finance, market risk, market news, standardization, competition and prices, market price, price maintenance and unfair competition, the relation of the State to marketing, the cost of marketing, and final criticism.

FOODS—HUMAN NUTRITION

Report of the committee on testing soft wheat flours, M. M. BROOKE (*Cereal Chem.*, 9 (1932), No. 4, pp. 406-428).—This annual report (E.S.R., 66, p. 686), consists chiefly of the following subcommittee reports:

Report of subcommittee on cake-baking method for testing soft wheat flours, L. H. Bailey (pp. 407, 408).—A white cake formula and method of procedure are submitted for adoption as a tentative method for testing soft wheat flours.

Report of the subcommittee on cake score-card, R. A. Barackman (pp. 409, 410).—No changes have been made in the values assigned in the 1931 score card, but it is recommended that "fat tolerance, sugar tolerance, and water tolerance be designated in reports in terms of minimum and maximum percentage (flour basis) which will not impair cake quality; that reports also include a statement of moisture, protein, and ash (calculated to 15 percent moisture basis), and H-ion concentration in terms of pH; that viscosity values be added to reports dependent on the findings of the viscosity committee; that final judgment of a cake flour be based on moisture, protein, ash, pH, tolerance figures, viscosity values, and score, with comments regarding faults."

Reports of the subcommittee on pie-flour tests, C. B. Kress (pp. 411-413).—This report discusses qualities to be considered in evaluating pie crust, including color, tenderness, flakiness, form, and dryness. A pie crust formula and method of procedure are described, and tables are given of physical and chemical tests of five types of flour and the grading of pie crust made from them. A mechanical sifting test indicating the quality of the crust by the amounts which can be made to pass through a no. 10 sieve is proposed.

Report of the subcommittee on tests for biscuit and self-rising flours, I. D. Whiting (pp. 414-419).—A tentative formula and procedure for baking biscuits are given, with results of collaborative tests for plain and self-rising biscuit flours. The results are also given of collaborative tests on the CO₂ content of self-rising flours as determined gasometrically.

Report of the subcommittee on testing of soft wheat flours for use in cookies, P. Brown (pp. 420-423).—This report includes a classification of machine made cookies, a formula and mixing procedure for making cookies in testing soft wheat flours, and the reports of studies of the effect of flour grade and of bleaching on the quality of cookies baked by the standard method.

Report of the subcommittee on hydrogen-ion concentration with special reference to the effect of flour bleach, E. E. Smith (pp. 424-428).—This report describes a preliminary study of the effect of chlorine bleach on certain soft wheat flours, as revealed by cake baking tests using bleached and unbleached flour from various flour streams. In general chlorine bleaching increased the score of cakes in almost every respect.

Testing the quality of flour by the recording dough mixer, C. O. SWANSON and E. B. WORKING (*Cereal Chem.*, 10 (1933), No. 1, pp. 1-29, figs. 22).—This paper describes the construction, operation, and application to flour testing of a recording dough mixer which is a modification of one described previously (E.S.R., 55, p. 692).

Variation in the weight of a given volume of different flours, I-III, E. GAEWE (*Cereal Chem.*, 9 (1932), Nos. 3, pp. 311-316; 5, pp. 531-534; 6 pp. 628-636, figs. 2).—Three papers are presented.

I. Normal variations.—As the result of an extensive series of measurements by the author and several collaborators of the weights of a cupful of sifted flour from hard and soft wheat milled in different sections of the country, the average weights per level cup of flour made from hard winter wheat and hard spring wheat were found to range from 111 to 114 g. This corresponds

closely to the 113 g reported by Woodruff (E.S.R., 48, p. 159) as the average weight of a cupful of hard wheat flour. Greater differences were found in the weights of soft wheat flour from different localities. The average weight of soft wheat flours milled in Missouri, Illinois, Indiana, and Ohio was 93 g per cup, and of samples from mills in the Pacific Northwest, Michigan, and the eastern part of the East Central region slightly less. The average value of 92 g is considered to be more nearly correct than the value of 100 g as given by Woodruff.

In measuring flour, one sifting is considered sufficient except with old flour. Packing is thought to have an appreciable effect on the weight per cup if more than enough for one cup is sifted at a time. Another factor tending to increase weight is the piling of considerable flour on top of the cup before leveling. With the unavoidable variations in weight per unit volume, it is thought advisable where possible, particularly in large scale cookery, to weigh rather than measure the flour for batters and doughs.

II. *The result of the use of different wheats.*—Further factors shown to have an effect upon the weight of a given volume of flour are the variety of wheat and the conditions under which the wheat is grown (dry or irrigated soil).

Six samples of flour made from American Banner wheat and 6 from Berkeley Rock wheat grown in different types of soil averaged 87.4 and 103.3 g per cup, respectively. The range in weight for the first variety in the different soils was from 83.2 to 91.6 g and for the other from 98.8 to 105.5 g, showing that the type of soil had less effect than the variety of the wheat.

The average weights per cup of samples of flour from wheat of 10 different varieties grown on dry and irrigated soils were 102.9 and 105.7 g, respectively. The values for the individual samples were consistently higher for the wheat grown on irrigated than on dry soil.

III. *Causes for variation, milling, blending, handling, and time of storage.*—Factors shown in this paper to affect the weight of a given volume of flour are the size of the flour granules, the moisture content of the flour, the relative humidity of the atmosphere (because of its effect on moisture content), and the temperature of the room in which the measurements are made.

The effect of the size of the flour granules was measured in two ways, by separating the granules with different sized sieves and by using flour separated into grades. In both, the smaller the granules the less was the weight of the flour per cup. With decreasing moisture content the weight per cup increased very rapidly to a point between 8 and 7 percent moisture, after which there was a decrease in weight. In a room with low humidity an increase in temperature from 20° to 30° C. resulted in a decrease in the weight per cup of the flour.

The effect of variations in the moisture content of the flour is emphasized as of considerable importance in home baking. The loss in moisture and change of weight in flour retained in heated homes in winter affect the ratio of flour to liquid to such an extent as to introduce an error when the flour is measured by volume sufficient to account for some of the failures in cake baking.

Attention is called to the fact that throughout the entire work the commercially milled flours from soft wheat which were examined weighed less than 100 g per cup and hard flours more than 105 g per cup. Weight per given volume is recommended as a simple and fairly accurate means of distinguishing between soft wheat flour and hard wheat flour and blends.

Report of the committee on the standardization of laboratory baking, D. A. COLEMAN (*Cereal Chem.*, 9 (1932), No. 4, pp. 404, 405).—This annual report

(E.S.R., 65, p. 890) consists chiefly of recommendations based upon the final report on the baking research fellowship (E.S.R., 68, p. 559).

Measuring and recording some characteristics of test sponge cakes, W. PLATT and P. D. KRATZ (*Cereal Chem.*, 10 (1933), No. 1, pp. 73-90, figs. 10).—Methods which have been developed for recording and in some instances measuring quantitatively the characteristics of test sponge cakes are described. The quantitative measurements include the specific gravity of the batter by weighing a standard cupful, a determination used in measuring the beating quality of eggs; cake volume, by determining with a planimeter the area of a cross section of the cake; texture, by determining the compressibility and the elasticity with an apparatus previously developed for bread; and toughness, by a tensile strength apparatus. Methods for recording without actual measurement include shape by drawing the profile of the cross section, shape and grain by photography, and flavor by a scoring method.

A method for measuring the rate of inherent staling is being developed, which depends upon the tensile strength, compressibility, and ratio of the compressibility under different weights. "It is believed that the time rate of change of compressibility or of tensile strength could be used as measures of inherent staling. These in turn, over any given period, could be best expressed as the slope of the curve or as units of change per day. In this way the relative keeping qualities of two cakes made in different ways, but kept under the same conditions, could be expressed numerically and compared."

Some new facts about molds and bread, O. SKOVHOLT and C. H. BAILEY (*Minnesota Sta. Bul.* 296 (1933), pp. 12, figs. 3).—This discussion of the various factors influencing the rate and extent of mold growth in bread includes a brief report of new experimental evidence obtained in the laboratory and commercial practice. Among the points brought out are the following:

Bread which has received a thorough enough baking to be salable will contain none of the spores of common bread mold having the ability to grow and reproduce. Dust particles carry mold spores to the surface of the loaf where they may develop while the loaf is cooling, but a relative humidity of at least 90 percent is required for visible mold development. Bread containing 6 percent milk solids retains moisture within the loaf better than milk-free bread. This consequently retards the formation of moisture between the loaf and the wrapper and hinders mold development. Plant sanitation is considered to be of greater importance than thoroughness of baking and cooling in reducing mold formation.

The authors conclude that there is no justification for reducing the milk solids content of bread to prevent mold.

Conserving food value, flavor, and attractiveness in cooking vegetables, R. LOUGHLIN (*U.S. Dept. Agr. Circ.* 265 (1933), pp. 12, figs. 5).—This circular discusses the nutritive value of vegetables, points to be considered in their purchase, storage, and preparation for cooking and serving, and methods of cooking to preserve nutritive value, flavor, texture, and color, and describes methods suitable for cooking and serving different types of vegetables. A table is included giving the quantity as purchased required for 5 or 6 servings, preparation for cooking, and the time for baking, steaming, or boiling of the more important vegetables.

Cooking quality of potatoes, M. D. SWEETMAN and P. S. GREENE (*Maine Sta. Bul.* 363 (1932), p. 274).—This is a brief progress report (E.S.R., 66, p. 496) on the measurement of various qualities of potatoes in relation to their mealiness.

The microbiology of frozen foods, L. H. JAMES (*Fruit Prod. Jour. and Amer. Vinegar Indus.*, 12 (1932), No. 4, pp. 110-113, 119).—This contribution

from the U.S.D.A. Bureau of Chemistry and Soils consists of a concise review of the literature on the subject, with a bibliography of 36 titles.

The relative digestibility by rats of the milk of five breeds of dairy cattle. W. B. NEVENS and D. D. SHAW (*Jour. Agr. Res. [U.S.]*, 46 (1933), No. 5, pp. 463-472).—Following the technic and management described previously (E.S.R., 68, p. 561), the apparent digestibility of the fresh whole milk of five breeds of dairy cattle (Ayrshire, Brown Swiss, Guernsey, Holstein-Friesian, and Jersey) was studied at the Illinois Experiment Station by 10-day digestion trials with rats.

The coefficients of digestibility for fat were high and showed no significant breed differences, the average values lying within the small range of 98.2 ± 0.13 to 99 ± 0.07 . The protein values were somewhat lower, the averages ranging from 89.7 ± 0.36 to 92.3 ± 0.14 . The total solids had somewhat higher coefficients of digestibility than the proteins, the average values for the different breeds ranging from 91.8 ± 0.15 to 93.3 ± 0.15 . In both proteins and total solids the breed differences were likewise considered insignificant. The sugars were almost completely digested.

The question of the copper content of milk and milk preparations [trans. title], E. REMY (*Ztschr. Untersuch. Lebensmitl.*, 64 (1932), No. 6, pp. 545-548).—Tabulated data are given on the composition of 10 samples of milk and milk preparations, including 2 samples of breast milk, 2 of fresh cow's milk, and 1 each of pasteurized market milk, a special milk for children, fresh goat's milk, evaporated milk, dried skim milk, and Yoghurt milk. The data include physical constants, proximate analyses, ash analyses (including phosphate (PO_4), copper, iron, calcium, and potassium), and the reducing capacity for 2,6-dichlorophenol-indophenol according to the Tillmans method.

Special attention was given to copper on account of reports in the literature of wide differences in the copper content of milk of different species. The Elvehjem-Lindow modification of the Blazzo method was used for this determination. The differences in copper content of the various types of fresh milk examined were considered to be insignificant. The average value for the various samples of cow's milk was 0.131 and for the 2 samples of breast milk 0.130 mg percent. Goat's milk had a content of 0.09 mg percent. The calcium-phosphorus ratios averaged 1:1.3 for cow's milk and 1:1.26 for breast milk. One sample of breast milk and 1 of fresh cow's milk had a reducing capacity of 5 cc per 100 g. The other sample of fresh cow's milk gave a value of 15, pasteurized milk 8, special milk for children 4.4, goat's milk 10, and Yoghurt milk 6.6 cc per 100 g.

Iron and copper in liver and liver extracts. A. E. MEYER and C. EGGEET (*Jour. Biol. Chem.*, 99 (1932), No. 1, pp. 265-270).—Data are reported on the iron and copper content, as determined by the methods of Elvehjem and Peterson (E.S.R., 58, p. 191) and Elvehjem and Lindow (E.S.R., 61, p. 612), respectively, of the whole liver and various extracts of the liver of horse, dog, beef, and hog. "In the livers investigated, horse, hog, and dog livers are uniformly high in iron, whereas beef liver contains considerably less. The copper is highest in beef liver, less in dog, horse, and hog liver. Only a part of these metals can be extracted with water. They are accumulated in the fraction which is precipitated with 67 percent alcohol. The fraction obtained afterward with higher grade alcohol (up to 93 percent) contains less copper and very little iron."

Iodine in nutrition in coastal Mid-China. W. H. ADOLPH and P. C. WHANG (*Chinese Jour. Physiol.*, 6 (1932), No. 4, pp. 345-352).—The investigation previously noted (E.S.R., 64, p. 581) has been extended to a study of the Shanghai-Soochow area, an east Mid-China area adjacent to the sea. Iodine was

found in considerable amounts in the vegetable foods in this area. The highest amount reported was for cabbage, 776 parts per billion of dry material. The marine foods, both plant and animal, were all rich in iodine. The lowest amount reported was for fish bladder 480, and the highest for *Laminaria religiosa* 240,000 parts per billion of edible portion. Crude sea salt contained from 40 to 247 parts per billion and a crude well salt 926 parts per billion. The calculated average iodine intake for this region was from 32 to 66y per day. The region is considered to be nongoitrous.

The role of minerals and vitamins in growth and resistance to infection, A. BROWN and F. F. TISDALL (*Brit. Med. Jour.*, No. 3758 (1933), pp. 55-57, figs. 2).—This general discussion is based largely upon the authors' laboratory and clinical experience (E.S.R., 67, p. 490).

Some effects of chlorophyll in the diet of the albino rat, F. R. EDWARDS and K. T. HOLLEY (*Georgia Sta. Bul.* 173 (1932), pp. 11, figs. 7).—Essentially noted from a preliminary report (E.S.R., 66, p. 763).

The nature of the foodstuffs oxidized to provide energy in muscular exercise.—IV, The use of protein as a fuel in exercise, A. CANZANELLI and D. RAPPORT (*Amer. Jour. Physiol.*, 102 (1932), No. 2, pp. 325-331).—Following the same technic as in earlier studies of the series (E.S.R., 59, p. 891), the authors have determined the respiratory metabolism of a dog during rest and exercise on protein feeding after starvation and fat diet and after carbohydrate diet and on mixed protein and carbohydrate feeding. The conclusion is drawn that "protein is a normal source of oxidative energy for muscular exercise, and its nonnitrogenous split products are as readily available for this purpose as are carbohydrate and fat."

Vital need of the body for certain unsaturated fatty acids.—III, Inability of the rat organism to synthesize the essential unsaturated fatty acids, H. M. EVANS and S. LEPKOVSKY (*Jour. Biol. Chem.*, 99 (1932), No. 1, pp. 231-234, figs. 2).—Evidence is presented showing that the body fats of rats reared on complete diets contain appreciable amounts of the fatty acids previously demonstrated to be essential (E.S.R., 67, p. 773), and that these substances are absent or greatly reduced in the carcass fat of rats reared on fat-free diets.

Ketosis during fasting in Eskimos, P. HEINBECKER (*Jour. Biol. Chem.*, 99 (1932), No. 1, pp. 279-282).—Supplementing earlier studies on the metabolism of Eskimos during fasting, three full-blooded Eskimo women in the same locality as in the previous study (E.S.R., 67, p. 87) were subjected to a 7-day fast, during which time daily collections of the urine were taken for analysis. The data obtained were consistent with those of the earlier studies in showing a lesser degree of ketosis on fasting than is the case with the average white person living in a temperate zone. One subject developed a much greater degree of ketosis than the other two, showing that even in the Eskimo the power to oxidize fats to completion is limited. It is thought that glucose, when available for oxidation, limits the demand for the oxidation of fat, thus tending to keep the subject above the threshold of ketosis.

On the motion of growth.—I, Introduction to the energetics of growth and metabolism. II, Human growth in weight from early fetal to adult life. III, The determination of ρ and the energetics of human basal metabolism, N. C. WETZEL (*Soc. Expt. Biol. and Med. Proc.*, 30 (1932), No. 2, pp. 224-227; 227-232, figs. 2; 233-236, fig. 1).—These three papers summarize "the major results of an extensive investigation into the general nature and mechanism of growth." In the first a mathematical equation is developed for the energetics of growth. This is applied in the second paper to the case of human growth in weight from the one-hundredth day of gestation to full adult life and in the third to the course of human basal metabolism through

the same period in terms either of unit or total heat production. The theoretical values obtained in the metabolism calculations are shown to have good agreement with actual values reported by Benedict and his associates.

Cost of work in relation to basal metabolism, J. T. McCLINTOCK and S. PAISLEY (*Soc. Egypt. Biol. and Med. Proc.*, 30 (1932), No. 2, pp. 162, 163).—Following the procedure of Benedict and Murschhauser (*E.S.R.*, 34, p. 280), the authors have determined the extra energy output caused by walking for 65 children, boys and girls, ranging in age from 11 to 14 years, with average values for cost per horizontal kilogram-meter of 0.6449 gram-calorie for the boys and 0.5949 for the girls. It was found that the general average for the entire group of boys was approximately 20 percent higher than the value of 0.538 gram-calorie reported by Smith (*E.S.R.*, 47, p. 562) as an average for 8 normal men. The average basal metabolic rate for the group of boys was 47.5 calories per square meter body surface, as calculated from the tables of Du Bois. This value was also 20 percent higher than that given for adult men in the same tables.

The suggestion that the energy cost of walking is directly proportional to the basal metabolic rate, as brought out by these results, led to calculations of the probable cost of walking for the different age groups of boys and girls in the present study by use of the Du Bois tables of basal metabolic rates for different ages. The figures, although not in perfect agreement with the determined values, were in such close accord as to justify the conclusion that the unit cost of work, such as walking, in normal individuals varies directly with the basal metabolic rate.

Vitamins and hormones: Their genetic, synergistic, and antagonistic relationship [trans. title], J. KÜHNAL and W. STEFF (*München. Med. Wchnschr.*, 80 (1933), No. 3, pp. 87-92).—The authors review and discuss recent literature, mostly from German sources and largely theoretical, pointing to an intimate relationship, either supplementary or antagonistic, between various vitamins and hormones.

Vitamin A in six varieties of frozen cherries, M. T. POTTER and M. A. DICKSON (*Jour. Home Econ.*, 25 (1933), No. 1, pp. 47-52, fig. 1).—In this contribution from the Washington Experiment Station, data are reported on the vitamin A content, as determined by the Sherman-Munsell method with slight modifications, of several types of cherries which had been frozen in the raw state and stored at subzero temperature. The quantities of the different types estimated to contain 1 unit of vitamin A were as follows: Montmorency (sour) between 0.25 and 0.375 g. closer to the lower level; Late Duke (hybrid) between 0.25 and 0.375; Royal Ann (sweet) between 0.25 and 0.375, closer to the upper level; Bing (sweet) approximately 0.375; and the Deacon and Lambert (both sweet) above 0.375 g.

"The cherry compares favorably with other fruits in vitamin A potency and may be ranked among the fruits as a rich source of this dietary factor."

The properties of halibut-liver oil, R. T. M. HAINES and J. C. DRUMMOND (*Brit. Med. Jour.*, No. 3769 (1933), pp. 559-561, fig. 1).—Data are reported on the physical and chemical constants of 8 samples of halibut-liver oil, 7 of which were known to be uncontaminated. Data are also included on the amounts of unsaponifiable matter in the oil, the iodine value and percentage of cholesterol in the unsaponifiable fraction, the vitamin A blue values as determined by the antimony trichloride test for the oils and corresponding unsaponifiable fractions, the content of vitamin A of 4 of the oils as determined by R. J. MacWalter by means of the Hilger spectrophotometer, and the calculated loss of vitamin A from these oils on extraction.

A graph correlating the values for the extinction coefficient at 3,280 Å in a concentration of 1 percent with the blue values obtained in the antimony trichloride test on these oils showed a striking straight line relation which is thought to point to the trustworthiness of the antimony trichloride test for determining the vitamin A values of halibut-liver oils of high potency.

Attention is called to the fact that direct treatment of halibut liver with live steam, which readily liberates oil from cod liver, does not break up the tissue and release the oil.

Vitamin A and the growth-promoting action of the egg yolk of birds [trans. title], H. VON EULER and E. KLUSMANN (*Hoppe-Seyler's Ztschr. Physiol. Chem.*, 208 (1932), No. 1-3, pp. 50-54).—The literature on the carotenoid pigments in egg yolk, including previous studies from the senior author's laboratory, is reviewed briefly, and experiments are reported in which an attempt was made to determine by comparisons of the absorption spectra some quantitative relationship between vitamin A and carotenoid pigments in egg yolk. A concentrate was prepared from egg yolk by coagulation with alcohol, extraction of the residue with ether, saponification of the extract, and further extraction with ether. After evaporation of the ether, the residue was dissolved in chloroform and examined spectroscopically.

Absorption bands were identified at 489, 457, and 430 mμ. The reaction product with antimony trichloride showed bands at 585 and 625 mμ. These values are not identical with those of vitamin A from cod-liver oil or with zeaxanthin or xanthophyll. A mixture of 30 percent zeaxanthin and 70 percent xanthophyll (the proportions in which these pigments are considered to be present in egg yolk) gave absorption bands with the antimony trichloride reagents at 589 and 660 mμ, and the same mixture with the addition of a highly concentrated vitamin A preparation values at 584 and 622 mμ.

A method of enhancing the vitamin A value of cod liver oil, E. R. JAMES, H. F. GROVER, and E. J. QUINN (*Soc. Expt. Biol. and Med. Proc.*, 30 (1933), No. 4, pp. 516-519, fig. 1).—An emulsion of cod-liver oil with malt extract, prepared by thoroughly agitating a mixture of 22.37 percent by weight of high-grade cod-liver oil with 77.63 percent of concentrated malt extract in a specially constructed apparatus operated under reduced pressure, was found to be superior as a source of vitamin A to the same amount of plain cod-liver oil or plain cod-liver oil plus the extract fed separately. In the comparison the Sherman technic was followed, the supplements being fed after the rats had ceased to grow and showed other symptoms of vitamin A depletion. Nine animals receiving 0.8948 mg of cod-liver oil daily in the form of the emulsion made an average gain of 39.7 g in the 35-day test period and were cured of all symptoms of vitamin A deficiency. In both of the other groups several of the animals died before the end of the test period, and those surviving made poor growth or lost weight and showed more or less severe xerophthalmia at the end of the test period.

The authors are of the opinion that the fine subdivision of the oil in the emulsified product favors a more complete absorption and utilization of the vitamin.

How does heating affect the vitamin A content of milk? [trans. title], M. LUNDBERG (*Biochem. Ztschr.*, 259 (1933), No. 1-3, pp. 27-29).—Fresh milk was found to have a vitamin A content equivalent to 7.6, milk pasteurized by heating for 30 minutes at 63° C. a value of 8, and milk brought to boiling in 10 minutes and cooked for 2 minutes a value of 6.7 Lovibond blue units per gram of fat. These figures are thought to point to a considerable destruction of the vitamin A content of milk on pasteurization by the holding process.

Carotene and vitamin A. H. GOLDBLATT and H. M. BARNETT (*Soc. Expt. Biol. and Med. Proc.*, 30 (1932), No. 2, pp. 201-204).—Crystalline carotene dissolved in Wesson oil and carrot oil diluted with Wesson oil were fed in graded doses of from 0.00025 to 0.008 mg of carotene content, as determined colorimetrically by comparison with $K_2Cr_2O_7$ solutions, as the sole source of vitamin A to rats which had ceased gaining weight for about 2 weeks on a vitamin A-deficient diet.

Three animals receiving the carotene solution in amounts equivalent to 0.00025 mg of carotene daily lost weight and died, one in 4 and the other two in 3 weeks, and two receiving 0.0005 mg gained 2.8 and 2.9 g, respectively, in the 8 weeks' period. In the experiments with diluted carrot oil one animal receiving 0.00025 mg daily lost weight but lived 4 weeks and the two receiving 0.0005 mg daily gained 3.9 and 3.8 g, respectively, in the 8 weeks' period. The authors, ignoring these slight differences, state that "the results show that of each solution a quantity containing 0.0005 mg (0.5 λ) of carotene was the minimum that just satisfied the requirements for a Sherman unit of vitamin A, that is, an average gain of 3 g per week for 8 weeks." They conclude that carotene is the only growth-promoting factor of the nature of vitamin A in carrots and the only pigment of any consequence in carrot oil.

Determinations of carotene in the endocrine glands of cattle [trans. title], R. NETTER (*Bul. Soc. Chim. Biol.*, 14 (1932), No. 10, pp. 1555-1559).—Following the same technic as in a previous study of the carotene content of ox adrenal glands (E.S.R., 66, p. 607), the author has obtained crystals of carotene from bovine ovaries, testicles, and hypophyses, but not from the thymus and thyroid glands.

The role of carotenoids in the animal body [trans. title], H. VON EULER and E. KLUSMANN (*Biochem. Ztschr.*, 256 (1932), No. 1-3, pp. 11-17).—In the first part of this report data previously obtained on chickens and new data on pigeons are summarized, showing the utilization in these species of xanthophyll in a manner similar to the utilization of carotene in mammals. In part 2 evidence is presented indicating that xanthophyll bears the same relation to vitamin E that carotene does to vitamin A.

Infection of accessory sinuses in vitamin A deficiency: The rôle of carotene in infection of the upper respiratory tract, R. G. TURNER and E. R. LOEW (*Jour. Infect. Diseases*, 52 (1933), No. 1, pp. 102-120, figs. 5).—Tests of the value of carotene as a source of vitamin A in the cure of infections of the upper respiratory tract of rats are reported, together with preliminary data regarding the stability and potency of solutions of carotene in olive oil, with and without certain stabilizers. The bacteriological technic was essentially the same as that followed in the previous study (E.S.R., 61, p. 292).

Carotene alone in olive oil remained unchanged in color from 20 to 30 days, in the same oil containing 0.1 percent quinhydrone from 30 to 60 days, and in the same oil containing 0.1 percent hydroquinone from 90 to 120 days or longer. Solutions of carotene containing 0.1 percent of vanillin faded more rapidly than those containing carotene alone, losing their color in from 10 to 20 days. Solutions kept in nitrogen faded more rapidly than those in contact with air.

In the animals receiving unfaded carotene, the dosage in general ranging from 0.049 to 0.14 mg daily, the percentage incidence of bacteria in the nasal cavities and middle ear was noticeably less than in the animals given faded carotene or receiving no source of vitamin A. The number of spontaneous suppurative lesions in the upper respiratory tract was reduced, xerophthalmia was cured in all of the animals, and normal health was regained in 74 percent.

The authors are of the opinion that carotene is more effective against invasion of bacteria in the upper respiratory tract than cod-liver oil, but state that

"before accurate data can be obtained regarding the standardization of carotene or comparison of it with cod-liver oil or vitamin A concentrates its stability must be assured, and the solvent used for administration must be of a nature most favorable for the absorption of carotene from the intestinal tract."

Blood cholesterol in dogs on an A deficient diet, E. P. RALLI and A. WATERHOUSE (*Soc. Expt. Biol. and Med. Proc.*, 30 (1933), No. 4, pp. 519-523).—Observations on the level of blood cholesterol in four dogs on a vitamin A-deficient diet are reported, showing a rise in cholesterol values coincident with the development of symptoms of vitamin A deficiency and a fall subsequent to the administration of a cod-liver oil concentrate or carotene. These findings are thought to substantiate the conclusions of other investigators that the metabolism of cholesterol is affected by the quantity of vitamin A available.

Influence of cooking and canning on the vitamin B content of beef and pork, F. W. CHRISTENSEN, E. LATZKE, and T. H. HOPPER (*Amer. Soc. Anim. Prod. Proc.* 1932, pp. 365-368).—In this study at the North Dakota Experiment Station, cuts of beef and pork were freed from visible fats, ground finely in a meat chopper, and divided into three parts. One of these parts was dried in a current of cool air at a temperature varying from 48° to 57° C., another cooked in a double boiler with frequent stirring until a temperature of 92° was reached and then cooled, dried, and ground, and a third packed in no. 2 tin cans, sealed, heated in a pressure cooker for 60 minutes at 15 lb. pressure, cooled, and the contents removed from the can, dried, and ground. All of the samples were finally packed in ½-pt. fruit jars, evacuated, sealed under partial vacuum, and kept in an electric refrigerator until needed.

In testing the meats for vitamin B, the pork was fed at a level of 0.45 g of the dried material, with average weekly gains of 4.7 for the raw, 4.2 for the cooked, and 3.4 g for the canned meat. All of the animals survived, and nearly all were in good condition at the end of the experiment. The beef was fed at levels of 4, 4.5, and 6 g per week. The gains on 4.5 g weekly were 3.9 g for the raw and 3 for the cooked, while there was a loss of 3.8 g on the canned beef. The animals receiving the canned beef did not eat as much of the basal diet or the beef as did the others.

The authors conclude that the pork used was 10 times as potent in vitamin B as the beef, and that there was some destruction of vitamin B on cooking at the lower temperature and still greater destruction on cooking in the usual pressure cooker. "The irregular results obtained with the beef suggest that possibly some unrecognized factor is involved, or that pork contains some factor, not found in beef, which protects vitamin B from destruction in the pressure cooker."

The sparing action of fat on vitamin B, IV, V, H. M. EVANS and S. LEFKOVSKY (*Jour. Biol. Chem.*, 99 (1932), No. 1, pp. 235-240, figs. 3).—In continuation of the series noted previously (*E.S.R.*, 67, p. 778), two papers are presented.

IV. Is it necessary for fat to interact with vitamin B in the alimentary canal to exert its sparing effect? (pp. 235, 236).—The question as to whether or not the beneficial effects of fat upon vitamin B are the result of the interaction of the two in the alimentary canal was answered in the negative by experiments in which litter-mate female rats reared on either a fat-free diet or one containing 25 percent cottonseed oil were given vitamin B at two levels by mouth and by interperitoneal injection. Although the growth response to vitamin B administered parenterally is always slightly less than when administered by mouth, the addition of fat to the diet caused practically the same improvement in growth in the animals receiving the vitamin in the two ways.

V. The role of glycerides of oleic acid (pp. 237-240).—With the use of the same technic as in the third paper of the series, tests were made of the sparing action for vitamin B of the glycerides of purified and commercial oleic acid. In an attempt to simulate a natural fat, the glycerides of commercial oleic acid and stearic acid were mixed in the proportion of 60 parts of the former to 40 of the latter and likewise tested for their sparing action.

In tests in which there was an inadequate supply of vitamin B, the results with the glycerides of commercial oleic acid were inferior to those with the glycerides of pure oleic acid which were as effective as natural fats. With adequate vitamin B, the glycerides of the commercial oleic acid were utilized nearly as well as those of purified oleic acid. Growth on the mixture of the glycerides of commercial oleic and stearic acids was superior to that on either one alone.

Coprophagy as a source of vitamin B (B₁), L. E. BOOHER and T. KANEKO (*Soc. Expt. Biol. and Med. Proc.*, 30 (1932), No. 1, pp. 69-73, figs. 2).—Eleven rats fed the Sherman-Chase (E.S.R., 66, p. 410) vitamin B (B₁)-deficient diet containing 53 percent of raw cornstarch supplemented with from 66 to 97 percent of their own feces lived longer and lost weight less rapidly or grew at a slower rate than the controls without the supplement. Only one of the group developed polyneuritis. This one and two others died before the end of the 8 weeks' experimental period. All of the animals in the control group died within the usual time, from 24 to 33 days after they had ceased to grow. Inasmuch as the greatest growth in the feces-fed group was only 4 g per week and most of the animals grew at a much slower rate or lost weight steadily, although more slowly than the control animals, the authors conclude that vitamin B (B₁) studies by the Sherman-Chase method are not seriously affected by the influence of coprophagy.

An improvement in experimental method for investigation of vitamin G, J. W. PAGE (*Soc. Expt. Biol. and Med. Proc.*, 30 (1932), No. 1, pp. 87, 88, fig. 1).—A small aluminum and leather harness for rats, designed to prevent the practice of coprophagy, is described and illustrated. Contrary to the findings of Booher and Kaneko, noted above, that coprophagy does not affect vitamin B (B₁) experiments, this practice has been found to interfere seriously with the accuracy of vitamin G (B₂) determinations. Data are given showing that the use of the harness described not only shortens the period necessary for the young rats to reach stationary weight on the vitamin G-deficient diet, but also makes the animals lose weight more rapidly and uniformly.

The effect of parboiling and milling on the antineuritic vitamin (B₁) and phosphate content of rice, W. R. AYKROYD (*Jour. Hyg. [London]*, 32 (1932), No. 2, pp. 184-192).—Samples of highly milled parboiled rice were found to be rich in vitamin B (B₁), while roughly milled raw rice was deficient in this vitamin. The polishings from parboiled rice contained less vitamin B than those from raw rice.

In the process of parboiling unhusked rice is soaked in water for from 24 to 36 hours, subjected to steam at atmospheric pressure for from 15 to 20 minutes, and subsequently dried in the sun. It is thought that in the steaming process the water-soluble vitamins contained originally in the germ and pericarp diffuse through the endosperm and are consequently not so completely removed on milling.

Vitamins B₁ and B₂ in tissues of normal and experimental rats, C. E. GRAHAM and W. H. GRIFFITH (*Soc. Expt. Biol. and Med. Proc.*, 29 (1932), No. 6, pp. 695-697).—The body tissues of rats on a stock diet were found to contain more vitamin B₂ than B₁, although not a rich source of either, and to be richer in vitamin B₁ than the tissues of rats fed the Evans and Burr vitamin B-free

diet supplemented with cod-liver oil, and with tikitiki and autoclaved liver as sources of vitamins B₁ and B₂, respectively. These results are thought to point to a more rapid depletion of vitamin B₁ than B₂ in the body tissues. It is also suggested that the sustained but subnormal appetite of rats on vitamin B₂-deficient diets, as noted in a previous report (E.S.R., 66, p. 98), may have been due to the presence of residual vitamin B₂ in the tissues, while the well-known failure of appetite in vitamin B₁ deficiency may be due to the more complete depletion of the tissues in vitamin B₁.

Production in dogs of a syndrome similar to sprue by diets deficient in vitamin B₁. D. K. MILLER and C. P. RHODES (*Soc. Expt. Biol. and Med. Proc.*, 30 (1933), No. 4, pp. 540, 541).—The diet used in the production of this syndrome was a modification of the Goldberger blacktongue-producing diet and consisted of the following ingredients: White corn meal 4,000, ground California black-eyed peas 500, washed casein 500, sugar 300, cottonseed oil 300, cod-liver oil 200, salt mixture (Cowgill) 50, and rice polishings 400 g. The corn meal, peas, and casein were mixed and cooked 2 hours in a steam cooker, after which the other ingredients were added. The animals were fed the diet ad libitum.

Some, but not all, of the 50 animals acquired symptoms similar in all respects to sprue. All of the animals lost weight. Blood changes were definite in 60 and striking in 30 percent. In the latter the average red cell count dropped from 6.44 millions to 3.105 millions and the hemoglobin from 87.7 to 56.4 percent. In the animals with severe anemia there were striking alterations in the bone marrow. In the long bones, the marrow, which is normally fatty, "was completely replaced by solid, deep purple-red tissue, macroscopically indistinguishable from the marrow of cases of pernicious anemia. Histological studies showed proliferation of endothelial cells and of megaloblasts with little tendency to maturation. The histopathological picture was quite similar to that seen in cases of sprue anemia or in pernicious anemia."

The Winesap apple as a source of vitamin C. M. T. POTTER (*Jour. Home Econ.*, 25 (1933), No. 1, pp. 52-56).—In this study, in which the author had the cooperation of E. L. Overholser, Winesap apples from trees not fertilized and from trees receiving applications of complete fertilizer were tested for their vitamin C content. Fruit of medium size, averaging 125 apples to the box, was harvested in October and stored at about 45° F. through the experimental period, which extended from November 3 to February 15.

The samples, which were prepared just before each feeding by wiping, coring, quartering, grinding finely, and weighing, were fed to guinea pigs in quantities of 5, 10, and 15 g daily. Of the 11 animals receiving the smallest quantity, 3 showed no scurvy, 3 mild, 3 moderate, 1 severe, and 1 very severe scurvy. All but 1 of the 12 receiving 10 g and the 2 receiving 15 g daily were protected from scurvy.

It was concluded that the level of protection for the Winesap variety is in the neighborhood of 10 g. In view of the variable responses of the animals receiving 5 g, the study noted below was undertaken to determine the possible effect of fertilization upon the vitamin C content of the Winesap apple.

The vitamin C content of the Winesap apple as influenced by fertilizers. M. T. POTTER and E. L. OVERHOLSER (*Jour. Agr. Res. [U.S.]*, 46 (1933), No. 4, pp. 367-373).—Using the same methods as in the study noted above, the authors have compared at the Washington Experiment Station the vitamin C content of Winesap apples from trees receiving applications of a complete fertilizer with those from trees on neighboring plats not fertilized. The apples were fed at a 5-g level in order that even slight differences in potency might be detected.

Of the 15 animals receiving apples from the nonfertilized trees, 4 died with marked scorbutic symptoms before the end of the experimental period, nearly

all lost weight, and all but 3 showed evidence of scurvy on post-mortem examination. The average scurvy score for the group was 10.6. Of the 15 animals receiving apples from fertilized trees, only 3 died of scurvy and the average scurvy score for the entire group was 6.

The data suggest that Winesap apples from trees receiving applications of a complete fertilizer appear to be a better source of vitamin C than apples from unfertilized trees. However, it is emphasized that these findings should not be interpreted as indicating that Winesap apples are an unsatisfactory source of vitamin C unless from trees receiving applications of a complete fertilizer. Differences were not apparent when the fruit was fed at the higher, 10-g, level.

Estimation and distribution of ascorbic acid (vitamin C) and glutathione in animal tissues, T. W. BIRCH and W. J. DANN (*Nature [London]*, 131 (1933), No. 3309, pp. 469, 470).—Data are tabulated on the ascorbic acid content, as determined by the authors' modification of the indophenol titration of Tillmans, of rat blood, muscle, liver, and kidney; sheep liver and eye lens; pig liver; rabbit liver and kidney; guinea pig liver (normal and scorbutic); and ox suprarenal cortex, together with the total quantity of iodine required for reduction of 1 g of the same tissues and the calculated quantities required for ascorbic acid determination, and the percentage of the iodine titer due to ascorbic acid.

The values reported show that tissues known to be rich in glutathione also have a high ascorbic acid content. "This coincident occurrence of the two substances has led us to formulate the working hypothesis that ascorbic acid and glutathione may be two linked factors in one system of oxidation in the animal cell. This has already led to the discovery of a thermolabile agent which is a catalyst for the dehydrogenation of ascorbic acid."

The effect of high doses of irradiated and non-irradiated ergosterol on the albino rat, J. T. HAUCH (*Soc. Expt. Biol. and Med. Proc.*, 30 (1933), No. 4, pp. 475-477).—This report summarizes the results obtained in a long-continued investigation of the toxicity for rats of doses of irradiated ergosterol, including a commercial preparation and a laboratory irradiated product varying from 100 to 465,000 times the therapeutic dose. The animals were kept on a stock diet and various rickets-producing diets, and the experiments were carried through several generations. Blood calcium and phosphorus determinations were made on representative animals at different stages, and all of the animals sacrificed or found dead were autopsied and microscopic sections of the various organs studied.

Toxic effects were not obtained except with extremely high doses. In animals on the stock diet with bread and milk, the first evidence of toxicity reported in adults was with a dosage of 93,000 times the curative dose administered for 12 months. Both young and adult rats on the stock diet, including bread and milk, plus 465,000 times the therapeutic dose showed immediate toxic effects. A change to a rickets-producing diet increased the susceptibility.

The results are thought to afford additional evidence that the toxicity of irradiated ergosterol is determined in part by the character of the diet, the more complete and better balanced diets acting in a more protective way.

Comparison of bone ash of rachitic rats treated with viosterol and with phosphate ion, C. A. LILLY (*Soc. Expt. Biol. and Med. Proc.*, 30 (1932), No. 2, pp. 175, 176).—Three groups of 7 rats each were placed at weaning on the Steenbock rachitic diet 2965, in one group unsupplemented, in another supplemented with viosterol equivalent in vitamin D potency to 3 percent of cod-liver oil in the diet, and in the third supplemented by $\text{Na}_2\text{HPO}_4 \cdot 12\text{H}_2\text{O}$ in amounts equivalent to furnish 0.4 percent of the secondary phosphate. After 28 days the animals were killed for ash determinations of the femurs. The ash content of

the femurs of the control animals was 28 percent and of the other two groups 45 percent of the wet weight of the bones.

These findings are thought to demonstrate that "the addition of Na_2HPO_4 in adequate amounts to a low phosphorus rachitogenic diet produces a bone ash comparable to the bone ash produced by adding pure vitamin D to such a diet."

Studies on vitamin G (B_2) with special reference to protein intake, H. C. SHERMAN and I. A. DERBIGNY (*Jour. Biol. Chem.*, 99 (1932), No. 1, pp. 165-171).—In the experiments reported, different levels of protein intake (6, 12, and 18 percent), were tested as to their influence upon the development of the so-called pellagra-like condition in rats on diets markedly deficient and only slightly deficient in vitamin G. An additional control group received a diet containing 6 percent protein and supplemented with a liberal supply of vitamin G.

In the two series of experiments with varying protein intake, the average rate of growth during the 8 weeks increased with the protein intake, the differences being greater between 6 and 12 percent than between 12 and 18 percent. The length of survival of the animals on inadequate vitamin G was also influenced by the protein intake. On the lowest intake none of the animals survived beyond 20 weeks, while 30 percent of those receiving 12 percent protein and 44 percent of those receiving 18 percent protein survived beyond this period.

One of the symptoms of vitamin G deficiency, the loss of hair in bilaterally symmetrical areas on the shoulders and back and around the eyes, was likewise more pronounced in the animals receiving only 6 percent protein. The results of the investigation are thought to give some credence to the earlier belief that protein supply had some bearing on the pellagra problem. "And insofar as the pellagra problem is to be regarded as nutritional, one should think not in terms of a choice between 'protein theory' and 'vitamin theory', but rather of a theory broad enough to take account of the possible participation of more than one nutritional factor."

Studies on vitamin G with special reference to protein intake, I. A. DERBIGNY (*Diss., Columbia Univ., New York, 1932, pp. 22, figs. 2*).—A more detailed report of the investigation noted above.

A new symptom complex in vitamin-G deficiency in rats, S. G. SMITH (*Soc. Expt. Biol. and Med. Proc.*, 30 (1932), No. 2, pp. 198-200, fig. 1).—In addition to the symptoms previously described in the literature as occurring in rats on vitamin G-deficient diets, the author observed in rats surviving longer than 70 days on the Sherman-Bourquin vitamin G-deficient diet (E.S.R., 66, p. 410) a characteristic dermatitis of the tail. This is described as a coating of brownish-yellow waxy material, growing progressively worse until the animal died or was given a vitamin G supplement, such as yeast autoclaved for 2½ hours at 15 lb. pressure, following which the condition gradually cleared up. Histological examination of sections of the tails of rats which had been maintained for 226 days on the deficient diet showed thinning and disorganization of the epithelium, almost complete atrophy and disintegration of the sebaceous glands, and atrophy and fragmentation of the fibrillar material in the corium, but with no cellular infiltration. These changes were also observed in the one animal of the 18 studied which died at the end of 70 days without showing any gross lesions.

In animals which were given the autoclaved yeast at a level of 10 percent of the diet for 36 days after the 226 days on the deficient diet, similar histological studies of sections of the tail showed complete regeneration of the epithelium and return to normal of the sebaceous glands and corium.

The same symptom complex was observed in 17 rats on a diet similar to that which human beings frequently developed pellagra (white corn meal, pork fat, cane sirup, white flour, and cane sugar). The tail lesions did not develop

in rats deprived of food but not water or water but not food, although in the latter group blood staining of the wrists, mouth, eyes, and nose often described as characteristic of vitamin G deficiency developed. Sections made from the tails of 16 control rats were entirely normal.

Hemoglobin regeneration in the anemic albino rat with dietary supplements of spinach, apricot, and liver, C. J. FARMER and H. E. CORY (*Soc. Expt. Biol. and Med. Proc.*, 29 (1932), No. 6, pp. 766-769, figs. 2).—The spinach and apricots used in this study were commercially canned samples, plain and puréed. These and beef liver were compared for hemoglobin regenerating potency by the usual rat-feeding tests. The depletion period was long, 70 to 80 days, during which time the hemoglobin content decreased from an initial value of 11 or 12 g to from 3.6 to 4.8 g per 100 cc of blood.

Hemoglobin regeneration to normal values was secured with 5 g of the puréed spinach, furnishing only 0.001 mg of iron. More rapid regeneration was secured with 10 and 20 g daily, but even the largest amount fed had an iron content of only 0.364 mg. The copper content in all cases was equal to or above the accepted minimum. The puréed samples of both spinach and apricots were more effective than the nonpuréed. Beef liver was about twice as effective as nonpuréed apricot and this in turn as the spinach, the approximate ratio of 4:2:1 being about the same as reported by Rabscheit-Robbins and Whipple (*E.S.R.*, 63, p. 897) for the relative efficiency of these materials for blood regeneration in dogs rendered anemic by bleeding. It is noted that hemoglobin regeneration was insignificant with acid solutions of the ash obtained from 5 g of puréed spinach, and also that chlorophyll extracted from 5 g of spinach appeared to have a toxic action.

Values are given for the iron and copper content of samples of puréed and leaf spinach.

Experimental rickets as a phosphorus deficiency disease, H. D. KAY and B. L. GUYATT (*Nature [London]*, 131 (1933), No. 3309, pp. 468, 469).—Evidence is presented briefly in support of the theory that a chronic defect of phosphorus "is the most important single factor in the production of experimental rickets in rats. This is very probably true in a large proportion of cases of human rickets also, vitamin D being of importance in the rat or human dietary only insofar as its presence enables the organism to increase the net intestinal absorption of phosphorus from the food."

A second factor of importance is the diminution of the phosphoric ester content of the red blood cells, which has been shown to increase following the administration of vitamin D.

Changes in phosphoric ester content of the red blood cells and the liver in experimental rickets, H. D. KAY (*Jour. Biol. Chem.*, 99 (1932), No. 1, pp. 85-94).—Evidence is presented showing that in experimental rickets in rats there is a slight fall in the kidney phosphatase, a slight rise in the bone phosphatase, and a fall in the intestinal phosphatase. It is also shown that various organs, particularly the liver and red blood cells, have a much lower content of acid-soluble phosphoric esters in experimental rickets, and that the addition of therapeutic agents causes an increase toward normal values.

These findings are considered to be of interest in connection with the phosphatase theory of salt deposition in growing bones, for it is pointed out that the bone enzyme, although not diminished in rickets, suffers from shortage of inorganic phosphate in the blood and of the phosphoric esters of the red blood cells.

The intestinal flora of rachitic rats before and after treatment with ultra-violet rays, A. F. HESS and J. C. TORREY (*Soc. Expt. Biol. and Med. Proc.*, 29 (1932), No. 6, pp. 761-766).—Only slight differences were noted in the bacterial flora in the intestines of normal, rachitic, and irradiated rats, although

there were marked differences in the pH of the intestinal contents which were more acid in the irradiated animals. These findings are thought to indicate that the change in reaction toward acidity following ultraviolet irradiation is due to an alteration in metabolism and not the result of bacterial activity.

Growth-promoting rachitogenic diets for rats, T. F. ZUCKER, L. HALL, L. MASON, and M. YOUNG (*Soc. Expt. Biol. and Med. Proc.*, 30 (1933), No. 4, pp. 523-525).—Criticism of lack of satisfactory growth in rats on the customary rickets-producing diets has been met by the development of two new rickets-producing diets which at the same time promote satisfactory growth for the period required. The limiting factor in previous diets was considered to be vitamin B (complex). Rice polishings were found to be more satisfactory than yeast for making up this deficiency. The first of the two diets, diet 746, which is said to have given good growth during a 3 weeks' experimental period, consists of casein 5 parts, egg albumin 5, patent flour 76, NaCl 2, spintrate 1, rice polishings 7, milk concentrate 1, cottonseed oil 2, and CaCO₃ 1 part. The other, diet 728, contains egg albumin 10, wheat gluten 10, and cornstarch 65.5 parts in place of the casein, egg albumin, and patent flour. The other constituents are the same except for 1.5 parts CaCO₃ in place of 1 in the other diet. The second diet is said to be very suitable for 7-day preventive tests. At the end of this time determinations of inorganic blood phosphate showed a mean of 3.7 mg percent for rachitic animals, 4.7 with partial, and 7.3 with complete prevention by cod-liver oil. Figures for bone ash obtained on the fat extracted dried femurs gave averages of 42 percent for the rachitic and 46 percent for the nonrachitic animals.

Prevention and cure of rickets in rats and antirachitic activation of ergosterol by cold quartz mercury lamp, H. GOLDBLATT (*Soc. Expt. Biol. and Med. Proc.*, 30 (1932), No. 3, pp. 380-383).—The effectiveness of the cold quartz mercury lamp in the prevention and cure of rickets was tested on rats receiving the Steenbock-Black rickets-producing diet 2965. In the preventive tests, exposure of part of the back at a distance of 5 in. from the lamp for a period of 3 seconds daily afforded complete protection. In the curative tests an exposure of 10 seconds daily induced advanced or complete healing in 2 weeks, while one of 5 seconds daily gave variable results. Longer periods of radiation in the preventive tests were without harmful effect except a change in the coloration of the fur to light yellow in animals irradiated for more than 1 minute daily. In the curative tests, animals irradiated for from 15 to 120 seconds daily showed complete healing in 2 weeks and those irradiated for 45 seconds or longer advanced healing in 1 week.

The exposure of 0.2 percent solution of ergosterol in olive oil to radiation at the same distance, 5 in., from the lamp, for 1, 5, 10, 20, and 30 minutes resulted in the antirachitic activation of all of the solutions. These were diluted so that 1 drop (0.025 cc) contained 0.002 mg of irradiated ergosterol and 0.001 cc of irradiated oil. This quantity of the solution irradiated for only 1 minute was sufficient to prevent and cure rickets in rats.

The antirachitic efficiency of New Orleans sunshine, H. S. MAYERSON and H. LATRENS (*Amer. Jour. Physiol.*, 102 (1932), No. 2, pp. 422-438).—Essentially noted from other sources (*E.S.R.*, 69, pp. 313 and 410).

Ultraviolet light intensity in Puerto Rico, II, L. G. HERNÁNDEZ (*Puerto Rico Jour. Pub. Health and Trop. Med.*, 8 (1932), No. 2, pp. 249-254).—In continuation of the investigation noted previously (*E.S.R.*, 66, p. 493), readings for the solar radiation in San Juan, P.R., as determined by the oxalic acid uranyl sulfate method, are reported for a 5-month period from April 1 to August 31, 1931, inclusive. The maximum reading obtained was 10.96 mg of oxalic acid decomposed per square centimeter for one hour on June 18, 1931. This figure

approximates closely the value of 10.81 mg obtained at the Texas Experiment Station in the summer of 1931 and reported in a private communication from M. A. Grimes.

Relation of adrenal cortex to development of scurvy, J. E. LOCKWOOD and D. G. and F. A. HARTMAN (*Soc. Expt. Biol. and Med. Proc.*, 30 (1933), No. 4, pp. 560-562, fig. 1).—In this preliminary report, scurvy scores and curves of weight changes are given for groups of from 9 to 10 guinea pigs each on a scorbutic diet, with the following treatment: (1) Basal diet alone, (2) basal diet plus 0.7 cc of orange juice daily, and (3) basal diet with 1 cc of cortin (injected). The other two groups consisted of guinea pigs from which one adrenal had been removed one week previous to the experimental period. One of these (4) received the basal diet alone and the other (5) with 0.7 cc of orange juice.

The lowest average scurvy score was that of group 5, followed in increasing order by scurvy score and loss of weight by group 2, groups 3 and 4, and the control group 1. Inasmuch as the removal of one adrenal is followed by hypertrophy of the remaining adrenal, with possible overcompensation in the production of cortin, the results are thought to point to the possibility that the adrenal cortex through cortin aids in the utilization of vitamin C. The question as to the possible presence of hexuronic acid (vitamin C) in cortin is thought to be answered in the negative by the fact that ether in which hexuronic acid is insoluble was used for the extraction.

The problem of dental caries, T. ROSEBURY (*Arch. Path.*, 15 (1933), No. 2, pp. 260-278).—This review of recent literature is presented under the headings clinical and pathologic aspects, etiology, the systemic approach, the local approach, and the bacteriology of dental caries. Concerning the relation of diet, the author states that "some factor concerned with the character of the diet is of importance in susceptibility to caries. The incidence of caries in children may be reduced by regulation of the diet, and typical caries may be produced in rats by dietary means. It now appears likely that this dietary factor is physical rather than chemical, acting locally in the mouth rather than through the agency of a dietary deficiency, but such deficiency may contribute to the process. The possible relationship to susceptibility to caries of other factors of a systemic or metabolic nature, and of factors influencing the structure of the teeth, cannot be excluded, but may be doubted pending the accumulation of additional evidence."

Numerous references to the literature are given as footnotes.

Failure to produce dental caries with high carbohydrate, and with extremely low fat diets, C. A. LILLY and J. D. GRACE (*Soc. Expt. Biol. and Med. Proc.*, 30 (1932), No. 2, pp. 176, 177).—The theory that a high carbohydrate diet tends to produce dental caries was tested by feeding three groups of 10 young rats each for a period of 6½ months on diets containing 66 percent of glucose, lactose, and maltose, respectively. At the end of the experiment the teeth, examined under light and magnification, showed no evidence of caries.

The suggestion that a diet extremely low in fat tends to produce caries was likewise tested, with negative results, on two groups of 5 young rats each. These groups were kept for 9 months on diets containing in one case only 5 percent of fat in the form of cod-liver oil and in the other the same quantity of butterfat.

TEXTILES AND CLOTHING

The quantitative chemical estimation of textile fibers, R. EDGAR, M. WESTON, F. BARR, E. FISHER, and J. ROSS (*Iowa State Col. Jour. Sci.*, 7 (1933), No. 2, pp. 57-61, pl. 1).—The work recorded in this contribution from the Iowa

Experiment Station dealt with five main subjects: The quantitative estimation of cotton cellulose in the presence of wool, silk, regenerated cellulose rayon, or cellulose acetate rayon; the quantitative estimation of regenerated cellulose in the presence of cotton cellulose, wool, silk, or cellulose acetate rayon; the quantitative estimation of silk in the presence of regenerated cellulose or cellulose acetate rayon; the quantitative estimation of wool in the presence of cotton cellulose, silk, regenerated cellulose, or cellulose acetate rayon; and the quantitative estimation of cellulose acetate rayon in the presence of wool, silk, or cellulose.

Both half-saturated chromic acid solution and Schweizer reagent were shown to be unsatisfactory for the quantitative separation of regenerated cellulose from cotton cellulose. Silk fibroin failed to dissolve completely in ammoniacal nickel hydroxide prepared in accordance with the previously recorded procedures, but 1 g of silk dissolved completely in 5 minutes at the boiling point in 70 cc of ammoniacal nickel hydroxide reagent "prepared by using 425 cc of aqua ammonia, sp. gr. 0.90, for a volume of 500 cc." Even with this improvement, however, "ammoniacal nickel hydroxide has been shown to be an unsatisfactory solvent for silk in the quantitative analysis of mixtures because the undissolved nickel hydroxide deposits on the fibrous residue and is extremely difficult of removal." Numerous other solvents and two hydrolytic methods were also investigated.

Under the second main heading are summarized the effects of dilute sodium hydroxide solutions, Fehling solution, alkaline copper glycerol, and acetone on the weight of viscose rayon, determined under the conditions in which these solvents are employed in the quantitative separation of textile mixtures.

In the third group of experiments it was shown that cellulose acetate rayon may be separated quantitatively from mixtures with silk by solution in acetone. Neither 70 percent acetic acid nor aniline were found satisfactory for the quantitative separation of cellulose acetate rayon from silk, and for the quantitative separation of regenerated cellulose from silk the hydrolytic method using hydrochloric acid, sp. gr. 1.05, is preferable to that employing sulfuric acid, sp. gr. 1.345.

"The use of sulfuric acid, sp. gr. 1.524, for 20 minutes at 25° C. has been shown unsatisfactory as a differential solvent for cotton or regenerated cellulose in the quantitative estimation of wool. The use of sulfuric acid, sp. gr. 1.345, for 24 hours at room temperature has been shown unsatisfactory as a differential solvent for cotton or regenerated cellulose in the quantitative estimation of wool. The effect on the weight of wool keratin is reported for acetone, alkaline copper glycerol, basic zinc chloride, calcium thiocyanate, calcium thiocyanate and calcium chloride, hydrochloric acid, sp. gr. 1.19, hydrochloric acid, sp. gr. 1.05, Schweizer reagent, and sulfuric acid, sp. gr. 1.345."

The use of acetone as a differential solvent for the cellulose acetates (other than the triacetate) of union textiles gave the best results and is the only method which may be used with all union textiles. "The results obtained by the method of direct solution are about the same (mean error of +0.20 percent) as those based on the weight of the residue; however, the indirect method is preferable because it is more rapid and is simpler of manipulation. Acetic acid has been shown unsatisfactory as a differential solvent in the direct estimation of the cellulose acetate of union textiles. The proximate analysis of a union textile for cellulose acetate by means of the determination of the acetyl value by the method of acid hydrolysis has been shown unsatisfactory.

"The use of 1:1 alcohol-water as a swelling medium and 0.5 N alcoholic sodium hydroxide as a saponifying agent has been shown the best (mean

error of +1.52 percent ester) of all the methods of alkaline hydrolysis for the acetyl value of cellulose acetate rayon in cotton mixtures. The cellulose acetate rayon studied (of usual acetyl content as compared with 15, 18, 24, 26, 47, 84, 97, 105, and 126) yielded acetyl values of 37.67, 37.76, and 37.92 (the theoretical acetyl value for cellulose diacetate is 34.96), respectively, by the Ost, Barnett, and Eberstadt methods."

HOME MANAGEMENT AND EQUIPMENT

The use of time by rural homemakers in Montana. J. E. RICHARDSON (*Montana Sta. Bul.* 271 (1933), pp. 28, fig. 1).—This study is similar to previous ones from Nebraska (E.S.R., 61, p. 196), Oregon (E.S.R., 62, p. 496), Rhode Island and Washington (E.S.R., 62, p. 598), and South Dakota (E.S.R., 63, p. 797). A total of 48 records for 7 consecutive days was secured in the fall months and 44 in the spring. Records were kept in both fall and spring by 26 homemakers.

The distribution of time followed a similar pattern to that in the other studies reported. Work of all kinds occupied an average of 62 hours 20 minutes in the fall and 65 hours 10 minutes in the spring, sleep 59 hours 50 minutes and 60 hours 35 minutes, and personal care and recreation 45 hours 50 minutes and 42 hours 15 minutes, respectively. Further analyses of the records are reported for the distribution of time among the different kinds of work and personal care and recreation, with a discussion of factors that may have affected the use of time.

Food purchasing for the home. R. D. BLINKS and W. MOORE (*Chicago: J. B. Lippincott Co., 1932, 2. ed., rev., pp. XIV+434, [pls. 3], figs. [49]*).—This is a revised edition of the text previously noted (E.S.R., 63, p. 88).

Electrical cookery. L. SMITH, M. M. MONROE, and P. S. GREENE (*Maine Sta. Bul.* 363 (1932), pp. 271-274).—This report includes a summary and discussion of records obtained from farm bureau and federated club women of the State in a survey of cooking practices, and of laboratory studies of heating equipment, utensils, and management problems involved in electric cookery.

MISCELLANEOUS

Summary report of progress [of Maine Station] for the fiscal year ending June 30, 1932. F. GRIFFEE (*Maine Sta. Bul.* 363 (1932), pp. I-III+233-308, pl. 1, figs. 21).—This bulletin contains, in addition to data not previously reported or noted elsewhere in this issue, a brief tribute to the late W. H. Jordan, by J. M. Bartlett (pp. I-III), and meteorological observations (pp. 304-306).

Agricultural research in New Hampshire: Annual report of the director of the New Hampshire Agricultural Experiment Station for the year 1932. J. C. KENDALL (*New Hampshire Sta. Bul.* 270 (1933), pp. 27).—The experimental work not previously noted is for the most part abstracted elsewhere in this issue.

[Recent accomplishments of the Oregon Station and substations] (*Oregon Sta. [Pamphlet, 1933], pp. 12, figs. 2; Branch Sta. [Pamphlets, 1933]—Harney Sta., pp. 8, figs. 3; Hood River Sta., pp. 10, figs. 4; John Jacob Astor Sta., pp. 8, figs. 5; Pendleton Field Sta., pp. 8, figs. 5; Sherman Sta., pp. 8, figs. 3; Southern Oregon Sta., pp. 8, figs. 4; Umatilla Sta., pp. [8], figs. 4; Oregon Livestock Sta., pp. 8, figs. 4*).—The experimental work reported in these folders not previously referred to is for the most part noted elsewhere in this issue. Meteorological data are also included in the reports of the Harney (Burns), Hood River, Pendleton, Sherman (Moro), Southern Oregon (Talent), Umatilla (Hermiston), and State Livestock (Union) Substations.

NOTES

California University and Station.—H. R. Tolley, professor of agricultural economics and agricultural economist and director of the Giannini Foundation, has been appointed chief of the section of special crops in the U.S.D.A. Agricultural Adjustment Administration. In this capacity he will organize the relief program for crops not listed as basic commodities under the act, a program centering largely around marketing agreements.

Colorado College and Station.—Dr. C. P. Gillette, for 43 years head of the department of entomology and director of the station from 1910 to 1932, terminated active connection with the college and station July 1, but it is expected that he will continue his research activities.

A. M. Binkley, associate professor of horticulture and associate horticulturist, has been appointed acting head of the department, with Dean and Director E. P. Sandsten retaining the position of professor of horticulture and State horticulturist. Albert F. Hoffman, formerly county agent at Cripple Creek, has been appointed assistant in horticulture in charge of the Mountain Vegetable Substation at Avon.

The work of the station section of bacteriology has been combined with the bacteriological work of the college and with Dr. I. E. Newsom, professor of veterinary pathology and veterinary pathologist, in charge.

Iowa College and Station.—Under a recent reorganization of activities, H. H. Kildee, head of the department of animal husbandry and vice dean of the division of agriculture, has been appointed dean of agriculture; M. D. Helser, head of the meat subsection of the station, as dean of the junior college; and Dr. R. E. Buchanan, head of the department of bacteriology and dean of the graduate school, as director of the station. President R. M. Hughes is for the present continuing as acting director of the division of agriculture, with George Godfrey as assistant.

Nevada Station.—The station chemist and the department of farm development are making an investigation in the lower part of the Lovelock Valley with the object in view of determining the permanency of the agriculture under the method of irrigation now being used there. In that part of the valley irrigation water is limited to such an extent that crops must usually be grown with two, occasionally three, light irrigations applied in such a way that very little is lost by seepage. The question is, How long will it take to add sufficient alkali salts to reduce crop production seriously, assuming that the salts added in the irrigation water are not removed? This investigation has been requested by residents of the irrigation district because of a refusal of loans by the Federal Land Bank on the ground that the constant accumulation of alkali salts might reduce the productivity and value of the land within the time limits of the loan.

The department of farm development is attempting to produce matured, well developed turkeys of lighter weight than those normally sold on the market. This project is in response to a demand for smaller sized birds based on the small size of present-day city families and of modern gas and electric ovens. In the first experiments the effect of varying the percentage of protein in the ration from 13 to 28 percent on the development of pinfeathers and on earliness of maturity will be determined. Later studies will deal with the effects of fats in the ration.

New Mexico College and Station.—Luther Foster, associated with the development of college and station work in the Rocky Mountain area from 1885 to his retirement in 1921, died at Las Cruces June 17 at the age of 84 years. He was a native of Iowa and one of the few remaining Civil War veterans in New Mexico. He was a member of the first graduating class at the Iowa College, that of 1872, and also received the M.S.A. degree from the same institution in 1888.

Among other positions, Prof. Foster had been professor of agriculture in the South Dakota College from 1885 to 1890 and director of the South Dakota Station from 1890 to 1898; professor of agriculture and botany in the Montana College from 1893 to 1896; professor of agriculture and director in the Utah College and Station from 1897 to 1900; and professor of agriculture and horticulture and director in the Wyoming University and Station from 1900 to 1901. In New Mexico he served as president and director from 1901 to 1908, as dean of the college and director of the station from 1908 to 1913, and as animal husbandman from 1913 to 1921.

Practically all of his work was carried on under pioneer conditions. Thus for New Mexico his final report as director states that when he assumed his duties there in 1901 the station organization included four departments, "with a working force of seven men, who in addition to their station duties gave instruction to all college classes pursuing their special lines of work." Under his direction considerable reorganization gradually took place, special prominence being given to irrigation and dry farming studies and to a rather wide range of problems of immediate importance to the large percentage of farmers new to New Mexico conditions. As he puts it, "a definite settled policy of station management, the reduction of much scattered, indefinite work to a few important lines, the energy with which the work was carried out, the coming in closer touch with the farmers of the State, and the better appreciation of the work by them, taken with the increased appropriation, are responsible for the substantial progress and constant development the station has made during the past 12 years." This modest statement, however, fails to give adequate credit to his substantial personal contribution there and elsewhere of wise and able management under conditions of special difficulty.

New York State Station.—A recent official decree of the Japanese Government has established the so-called Breed method devised at the station for the direct counting of bacteria in milk, cream, and other dairy products as the approved method for the control of the sanitary quality of the market milk supply of Japan. A Japanese version of the directions for using the method has been prepared, and about 500 milk inspectors in Japan have been trained in its use. A recent survey of public health and milk plant laboratories by the committee on standard methods of milk analysis of the American Public Health Association has revealed that in the United States considerably more than a million samples of milk are examined annually by the method.

A rock garden, including a large collection of native wild flowers, is under construction.

Pennsylvania College and Station.—Effective July 1 the Institute of Animal Nutrition of the college, which heretofore has been a separate division cooperating with but not responsible administratively to the School of Agriculture and station, has been given the status of a department of the School of Agriculture and station.

Dr. F. F. Lininger, professor of agricultural economics and agricultural economist, has been granted leave of absence from August 7 to February 7, 1934, and from June 1 to 30, 1934, for the purpose of participating in a study

of the administration of the Agricultural Adjustment Act to be made by the Brookings Institution of Washington, D.C.

Clemson College and South Carolina Station.—Under a reorganization program recently approved by the board of trustees, H. W. Barre, who has been director of the station for 18 years, has also been appointed dean of the School of Agriculture. This linking together of teaching and research is expected to bring about a more effective utilization of the personnel and financial resources of the institution. G. H. Aull, for 12 years assistant director of research, has been appointed agricultural economist and assistant director of the station. He will head the joint research and teaching department of agricultural economics, but will continue to assist in the general administration of the station.

Virginia College and Station.—D. R. Forrester, assistant animal husbandman, resigned June 30. E. L. Wood and M. L. Bobb have been appointed assistants in entomology. The doctor of philosophy degree was conferred in June by the University of Virginia on Dr. L. E. Starr, assistant professor of zoology and animal pathology and assistant animal pathologist; by the University of Rochester on A. D. Pratt, assistant professor of dairy husbandry and assistant dairy husbandman; and by the University of West Virginia on A. B. Groves, assistant plant pathologist.

In the department of agricultural economics and rural sociology, Dr. W. E. Garnett, professor of rural sociology and rural sociologist, and A. C. Seymour, assistant rural sociologist, have been assigned full time to station work, and B. L. Hummel, rural sociologist, full time to extension. J. M. Ellison, field assistant in rural sociology, who has been on leave for graduate study at Drew University, resumed his duties at the station June 10.

West Virginia University and Station.—Under a new plan adopted by the board of governors, reorganization of the divisions of the College of Agriculture under a single administrative head is announced. All resident teaching of agricultural students, farm research, and extension work will be coordinated under the direction of Dr. F. D. Fromme, dean of the college and director of the station, who now also becomes director of the extension division. J. O. Knapp, district county agent for the southern counties, has been appointed assistant director of extension; Russell H. Gist, district agent for the northern counties, State leader of county agents; and C. H. Hartley, formerly assistant director of extension, State leader of boys' and girls' club work. Offices of all these officials will be maintained in Morgantown. It is hoped by this new set-up so to reduce the costs of administration of the extension program that a larger portion of the funds may be devoted to the work in the counties, while the work of the college will become more closely knit with the research and extension program of the university.

Reorganization in the field of biology has also been undertaken. Where formerly the various branches of this subject were distributed among several colleges of the university, most phases are now being coordinated under a single directing head and combined into one division of the College of Agriculture. Dr. C. R. Orton, formerly head of the department of plant pathology, has been given charge of the new department, which embraces all basic sciences related to biology, including botany, zoology, bacteriology, plant diseases, and forestry extension. In addition the research in plant diseases carried on by the station continues under Dr. Orton's direction. The change is expected to result in a broadening of service which the new department can offer along biological lines, including the training of graduate students.

EXPERIMENT STATION RECORD

Vol. 69

OCTOBER 1933

No. 4

EDITORIAL

A HANDBOOK OF THE AGRICULTURAL EXPERIMENT STATIONS IN TEMPERATE COUNTRIES

The International Institute of Agriculture at Roma has undertaken a much needed service in its compilation of a handbook entitled *Les Institutions d'Expérimentation Agricole dans les Pays Tempérés*, bibliographical details regarding which are noted on page 621. This handbook supplements *Stations Expérimentales et autres Institutions Officielles ou Privées s'occupant du Développement et de l'Amélioration de l'Agriculture dans les Pays Chauds*, published in 1931 (E.S.R., 66, p. 88), as well as the Institute's series of publications on educational and research institutions concerned with special subjects, such as agricultural engineering and zootechny.

The aim in this work has been to cover through these various publications the organized agricultural research of the world. This is obviously an ambitious venture, and one which had not been seriously attempted since the revision in 1904 of Bulletin 112 of the Office of Experiment Stations, entitled *Agricultural Experiment Stations in Foreign Countries*. The period of more than a quarter century which has elapsed since that publication was issued has been one of unprecedented development of agricultural experimentation, and despite the inevitable set-backs incident to the World War and the prevailing world-wide depression, active participation in agricultural research has become the accepted governmental policy in every civilized country of the globe.

The restriction of the Institute's latest volume to the temperate regions has eliminated from its pages all reference to Africa, Central America and the immediately adjoining territories, much of Australia, South America aside from Argentina, and most of Asia except China and Japan. Yet a book of about 300 pages remains, and mention is made of fully 1,300 institutions.

The arrangement of the material is by continents and countries. About 175 pages are devoted to Europe, and North America (Canada and the United States) receives over 50 pages. For each country a brief statement is given as to the general plan of organization of its agricultural research, and this is followed by accounts of individual institutions which take up such matters as their location and date of establishment, the amount and sources of revenues, the acreage and nature of the soil, the number and character of their personnel, their plan of work and accomplishments, and their publications and

other methods of disseminating results. The language used in the handbook is French, but in many cases the official title of each institution is repeated in its original form.

The basis of information was an institutional questionnaire, and where this was fully attended to the data are correspondingly complete and authoritative. Unfortunately, not all institutions responded, and as a result there are gaps which are sometimes disconcerting. The situation in Canada, for example, is very completely depicted as regards the Central Experimental Farm at Ottawa and the 22 stations and farms associated with it, but of the work affiliated with the colleges of agriculture there is mentioned only that in Ontario and Nova Scotia, no reference being made to that of MacDonald College and the Oka Agricultural Institute in Quebec nor that of the Universities of Alberta, British Columbia, Manitoba, and Saskatchewan. Somewhat the same situation prevails as regards certain other countries, and for a number (among them China, Japan, and the Union of Soviet Socialist Republics) lists without further details are all that is provided.

For the United States a clear interpretation is given of the system of State experiment stations, and although there are some variations in treatment, for practically all of the individual stations the data supplied are reasonably complete and comparable. Little account has been taken, however, of the research work of the Federal Department of Agriculture, either in Washington or elsewhere, and no mention is made of its many important field stations, such as the Northern Great Plains Station at Mandan, N.Dak., the livestock station at Jeanerette, La., or the range experiment station of nearly 57,000 acres at Miles City, Mont.

Notwithstanding these and other rather serious omissions, the handbook should prove very useful. The experiment stations in the United States, for example, should find it a valuable source of additional information as to many of the entries in the selected list of agricultural research institutions and library centers in foreign countries recently prepared independently by this Office with somewhat different objectives. Much of this information has not hitherto been available, and it should be of great service in facilitating decisions as to exchange relationships and similar matters. The Institute is to be congratulated for its initiative and persistence in collecting and assembling the large amount of data which the handbook contains. Not only should this information be very helpful to the Institute itself as a major step toward what it is hoped will ultimately become "a complete and up-to-date inventory of the agricultural institutions of the world", but by enlightening these institutions as to each others' work and facilities it should promote closer contacts and more effective utilization of their resources.

RECENT WORK IN AGRICULTURAL SCIENCE

AGRICULTURAL AND BIOLOGICAL CHEMISTRY

Transference and conductivity studies on solutions of certain proteins and amino acids with special reference to the formation of complex ions between the alkaline earth elements and certain proteins, S. MIYAMOTO and C. L. A. SCHMIDT (*Jour. Biol. Chem.*, 99 (1933), No. 2, pp. 335-358, figs. 12).—The data obtained in the experiments recorded indicate that within the limits of accuracy of the transference experiments, the sodium salts of casein, dephosphorized casein, aspartic acid, and glutamic acid, and the calcium and barium salts of the two last-mentioned amino acids do not yield complex ions; whereas, solutions of the calcium salts of casein and dephosphorized casein yield complex ions in solution. It was shown also that the number of complex ions in solutions of the calcium salt of dephosphorized casein is about 10 percent less than in solutions of calcium caseinate. It is concluded that the phosphoric acid in casein is responsible to the extent of about 10 percent for the complex ions in solutions of calcium caseinate. The hypothesis that solutions of casein in the hydroxides of the alkaline earth elements yield complex ions due to step dissociation is advanced.

Attempts to apply Ostwald's dilution law to solutions of aspartic acid, glutamic acid, and glycine indicated that these amino acids tend to obey the dilution law only in extremely high dilutions.

Sulfur in proteins.—V, The effect of alkalis upon cystine, with special reference to the action of sodium hydroxide, C. J. B. THOR and R. A. GORTNER (*Jour. Biol. Chem.*, 99 (1933), No. 2, pp. 383-403).—Continuing a serial contribution (*E.S.R.*, 63, p. 501) from the Minnesota Experiment Station, the authors report a study of the decomposition of *l*-cystine by aqueous potassium, sodium, and barium hydroxides, special attention having been given to the mechanism of the sodium hydroxide reaction.

All the alkaline mixtures which were studied removed nitrogen from the cystine molecule at very nearly the same rate as sulfur. Practically all of the nitrogen remaining in solution after the decomposition of cystine by alkalis was in a form determined by the Van Slyke method for α -amino nitrogen. Cystine was found to be definitely more stable toward boiling 4 *N* NaOH than is cysteine. Increasing concentrations of NaOH caused decreasing cystine destruction as measured by residual nitrogen, sulfur, and cystine. The fall in optical activity of *l*-cystine in alkaline solutions was found considerably more rapid than the decomposition of cystine. As regards nitrogen and sulfur elimination and cystine destruction, 4 *N* NaOH and 4 *N* KOH acted on cystine to practically the same extent. Further, "the small extent of deamination of cystine by NaOH and KOH which has been reported by several workers is due to an actual stability of the cystine and not to the formation of peculiar products under these conditions. This has been proved both by analysis and by the isolation of the crystalline cystine in 40 percent yield from cystine which had been boiled for 12 hours in 4 *M* NaOH solution.

"The relatively great stability of cystine toward NaOH (and presumably also KOH) appears to be the result of a secondary reaction between some decomposition product and undecomposed cystine leading to stabilization of the latter. This is indicated by the type of reaction curves obtained and by the fact that the isolated residual cystine was found to decompose in exactly the same manner as the original L-cystine. Such a stabilization hypothesis is presented.

"It is probable that the ether- and alcohol-soluble fraction, obtained by Gortner and Sinclair [E.S.R., 63, p. 501] by boiling cystine for 24 hours with saturated Ba(OH)₂, consisted of cysteine mixed with nonnitrogenous products, since a sample after standing for somewhat over a year had changed markedly in physical properties and was found to contain a fair proportion of L-cystine."

Preparation and study of the cereal glutelins (*Nebraska Sta. Rpt.* [1932], pp. 26, 27).—Experimental findings are briefly presented.

β -amino-n-valeric acid, H. D. DAKIN (*Jour. Biol. Chem.*, 99 (1933), No. 2, pp. 531-535).—The new amino acid was formed by the action of ammonia under pressure on propylideneacetic acid, which, in turn, was prepared by treating the ethyl ester of α -bromo-n-valeric acid with quinoline. The melting point was not sharp, decomposition beginning between 160° and 165° C., whereas the compound did not melt clear below 185°. The copper salt, the phosphotungstate, the reineckate, and the formation of β -uramido-n-valeric acid, 4-ethylhydrouracil, and 1-phenyl-4-ethylhydrouracil are described.

Cuprous glutathione, N. W. PRIE (*Biochem. Jour.*, 26 (1932), No. 1, pp. 75-79, fig. 1).—Modifications of detail in the preparation of glutathione from yeast cells are noted, together with a procedure for the preparation of the cuprous salt of glutathione. The crystallographic constants of glutathione are given, as are also the optical rotation (+45.4 to +45.8 as for the mercury green line at 16.5° C.) of cuprous glutathione. Finally, "evidence is brought forward to show that there is no reason to assume the existence of a cuprous derivative of oxidized glutathione, insoluble in weak acids."

The nature of plastein, S. J. FOLLEY (*Biochem. Jour.*, 26 (1932), No. 1, pp. 99-105, figs. 2).—"The evidence in favor of the view that plastein is a synthetic product is regarded as inconclusive.

"The molecular weight of plastein was found by the ultracentrifugal method to be 1,000 or less. A determination of the nitrogen distribution of plastein shows that this substance contains less amide-N and more monoamino-acid-N than egg albumin, the protein from which it was derived. The significance of these differences is unknown. The phenyl isocyanate derivative of plastein has been shown to consist of at least two fractions with equivalent weights of the same order as that of proteose. Plastein thus appears to consist of a mixture of substances."

On the purification and constitution of theelol, D. W. MACCORQUODALE, S. A. THAYER, and E. A. DOISY (*Jour. Biol. Chem.*, 99 (1933), No. 2, pp. 327-334).—Continuing their earlier work on this group of hormones (E.S.R., 64, p. 710), the authors describe an improved method for the purification of theelol based on the insolubility of the alkali metal salts in solutions of hydroxides of these metals. Prolonged treatment of theelol with strong alkali did not alter its physiological activity, optical rotation, or melting point.

Treatment with ketone reagents failed to reveal the presence of any theelin in routine preparations of purified theelol. Alkali fusion of theelol resulted in the formation of a phenolic dibasic acid, C₂₀H₂₀O₆. The methyl ether of this acid on treatment with acetic anhydride and distillation in a vacuum yielded an acid anhydride, C₂₀H₂₀O₆. No ketone was formed. "The most probable conclusion to be drawn from these facts is that the theelol molecule contains a

5-membered carbon ring bearing two secondary hydroxyl groups on adjacent carbon atoms." Catalytic reduction of theelol by means of a nickel catalyst yielded a hexahydro derivative insoluble in alkali. Desoxotheelin was prepared by the Clemmensen reduction of theelin and found to have the formula, $C_{10}H_{16}O$. This substance proved slightly soluble in dilute aqueous alkali.

An extension and a limitation of the thiocyanate method for the preparation of 2-thiohydantoins, B. H. NICOLET (*Jour. Biol. Chem.*, 99 (1933), No. 2, pp. 429-433).—In a contribution from the U.S.D.A. Bureau of Dairy Industry the author describes the preparation of 1-acetyl-2-thio-5-methyl-5-acetylaminohydantoin, 2-thio-5-methyl-5-acetylaminohydantoin, 1-benzoyl-2-thio-5-benzoylaminomethylhydantoin, and 2-thio-5-benzoylaminomethylhydantoin; and explains the failure of the reaction in certain instances as more likely to be due to "a stabilization of the azlactone ring to such an extent that addition of HNCS no longer takes place," than to an abnormal azlactone structure arising from some unknown cause.

Some properties of the enzyme glyoxalase, J. O. GIRŠAVIČIUS (*Biochem. Jour.*, 26 (1932), No. 1, pp. 155-161, figs. 3).—A method for estimating active mandelic acid in tissue extracts by extracting the acid with amyl alcohol and increasing the optical rotation by the addition of uranyl nitrate enabled the author to determine the effect of toluene and of various buffer substances on the activity of glyoxalase, together with the pH activity curve of the enzyme. Borate buffer mixtures appeared to have little effect upon the action of the enzyme, whereas phosphate buffers had a marked inhibitive influence and diethyl barbiturate buffers a strong inhibitive effect.

Milk peroxidase: Its preparation, properties, and action with H_2O_2 on metabolites, with a method for determining small amounts of H_2O_2 in complex mixtures, K. A. C. ELLIOTT (*Biochem. Jour.*, 26 (1932), No. 1, pp. 10-24).—"A crude, but considerably concentrated preparation" of milk peroxidase, "practically free from catalase" was obtained by means of an ammonium sulfate fractional precipitation method of which the working detail is given. The activity of this preparation was found to degenerate very slowly at temperatures of from 0° to 5° C., and the enzyme was active through a pH range of from about pH 4 almost to pH 10. A color appeared to be associated with the enzyme, and hemochromogen bands were observed. Such hydrosulfyl compounds as cysteine, glutathione, and denatured proteins interfered with tests for peroxidase with benzidine, gualacum, and to some extent also with those made with *p*-phenylenediamine. This appeared not to be an inhibition of the enzyme, as with hydrogen sulfide. It seemed rather to be due to the reduction of the colored reaction products by hydrosulfyl compounds.

A method of estimating hydrogen peroxide in very small amounts (1 mg in 35 cc) by measuring the evolution of molecular oxygen by manganese dioxide is described. "The volume of gas obtained is affected by the presence of proteins, phosphate, acid, etc., but in given conditions it is proportional to the hydrogen peroxide initially present." Conditions under which nitrate could be quantitatively oxidized by hydrogen peroxide with peroxidase, as shown by the consumption of the hydrogen peroxide and the disappearance of nitrite, are also specified. Under similar conditions tyrosine and tryptophan were found to be oxidized to colored products.

"Under the conditions in which nitrite is quantitatively oxidized, no oxidation by hydrogen peroxide and peroxidase of the following substances was obtained: Formate, acetate, oleate, stearate, triolein, ethyl alcohol, glucose, glycerol, acetaldehyde, β -hydroxybutyrate, lactate, glycine, phenylalanine, histidine. Dihydroxyacetone and phenylglyoxal are oxidized by very dilute hydrogen peroxide without peroxidase."

Iron in relation to tyrosinase, C. E. M. PUGH (*Biochem. Jour.*, 26 (1932), No. 1, pp. 106-117).—Determinations of the iron content of tyrosinase preparations were considered inconclusive with reference to the question as to the presence of iron in the molecule of the enzyme itself. The coloration of solutions of tyrosine and of paracresol by tyrosinase was shown to be accelerated by the presence of small quantities of various salts, however; an observation which "provides indirect evidence that hydrogen peroxide is produced during the action of tyrosinase." It was further observed that "the oxidation of monohydric to *o*-dihydric phenols by hydrogen peroxide with ferrous salt is less specific than the action of tyrosinase, and provides only a very imperfect imitation of the action of tyrosinase. . . . The loss in activity of tyrosinase from mealworms on dialysis may be prevented by carrying out the dialysis into alkaline buffer solution, and is therefore not due to loss of iron or other specific salts."

Growth of *Aspergillus versicolor* on higher paraffins, S. J. HOPKINS and A. C. CHIBNALL (*Biochem. Jour.*, 26 (1932), No. 1, pp. 133-142).—A mold form "best described at the present time as a strain of *A. versicolor* (Bullemin) Tiraboschi" was found capable of utilizing solid paraffins, both of odd and of even number of carbon atoms, up to $C_{27}H_{56}$ but not $C_{28}H_{58}$, the determinable products of metabolism in the case of the large scale culture on the heptacosane, or $C_{27}H_{56}$, preparation being only carbon dioxide and the mold mycellum. "Indirect evidence has, however, been obtained from experiments with higher ketones on which the mold grew vigorously, and with secondary alcohols on which no growth was obtained at all. It appears that the primary product of oxidation of a paraffin is a ketone or polyketone, and that further-oxidation results in the production of shorter fatty acids which are then metabolized in the usual way."

Characteristics of oxidation by *Azotobacter*, H. LINEWEAVER (*Jour. Biol. Chem.*, 99 (1933), No. 2, pp. 575-593, figs. 6).—The author of this contribution from the U.S.D.A. Bureau of Chemistry and Soils reports *A. vinelandii* as capable of oxidizing, by means of molecular oxygen, a large number of compounds including glucose, lactate, pyruvate, succinate, acetate, malonate, malate, tartrate, fumarate, ethyl, propyl, and butyl alcohols, formaldehyde, and *l*-tyrosine. "It does not appreciably oxidize formate, acetaldehyde, glycollate, oxalate, cystine, or *L*-cysteine; *L*-leucine is oxidized only very slowly if at all. Maleate, a stereoisomer of fumarate, is not oxidized. The formation of intermediate compounds has been specifically demonstrated in the cases of malonate and ethyl alcohol, the intermediate being acetic acid in both cases. In general, if a substrate is oxidized at all, it is oxidized practically entirely (at least 95 to 100 percent) to CO_2 and water.

"The presence of a malonate carboxylase enzyme has been demonstrated. The presence of typical dehydrogenases has been demonstrated by the methylene blue technic and certain narcotics.

"The velocity of oxidation of many substrates increases at first, over a period of several hours, before finally attaining a more or less constant value. Either intermediate compound formation or enzyme formation may be involved. The velocity of oxidation with mixed substrates is in general not additive. The Q_{10} values for the various substrates oxidized was very high compared to that for other organisms. The maximum value for many substrates under ideal conditions varies from 1,000 to 4,000.

"The effect of HCN and H_2S indicated heavy metal catalysis of respiration. The Hecht-Eicholtz reagents suggest but do not prove that Cu is involved." The 50 percent inhibition concentrations for the alcohol, urethane, and urea

homologous series are reported. The inhibition was not found to be a function of age, and in the case of propyl and butyl alcohols was found reversible.

Bacterial metabolism.—I, **Lactic acid production by haemolytic streptococci**, L. F. HEWITT (*Biochem. Jour.*, 26 (1932), No. 1, pp. 208-217).—In a salt solution buffered with bicarbonate and containing glucose and 10 percent of meat broth (in which excellent growth of hemolytic streptococci was obtained), "about three quarters of the glucose broken down in hemolytic streptococcus cultures yielded lactic acid, and this proportion remained remarkably constant over a range of cultural conditions, thus indicating a relatively simple fermentation process. Glucose breakdown was much more rapid in matt virulent cultures than with the glossy variants in the case of the strains investigated. Metabolic differentiation of bacterial variants is thus indicated."

The specific carbohydrate of the tubercle bacillus, G. A. C. GOUGH (*Biochem. Jour.*, 26 (1932), No. 1, pp. 248-254).—The isolation of the specific carbohydrate from tubercle bacilli and from the medium on which they have been grown is described. Acetylation of the carbohydrate with acetic anhydride and pyridine yielded a water-insoluble derivative from which the carbohydrate could be regenerated by alkaline hydrolysis without detectable loss of specific precipitating activity. Hydrolysis of the carbohydrate with acids yielded mannose, *d*-arabinose, galactose, and a mixture of acids which partially lost their acidic nature and gave mannose on prolonged hydrolysis. "Evidence of the presence of an acid, possibly glycolic, was obtained, but no glycuronic acid could be detected."

The glyceride fatty acids of forage grasses.—I, **Cocksfoot and perennial ryegrass**, J. A. B. SMITH and A. C. CHIBNALL (*Biochem. Jour.*, 26 (1932), No. 1, pp. 218-234).—In a somewhat detailed investigation of the glyceride-bound fatty acids of the two grasses named a highly unsaturated condition of the acids taken together and a relatively low proportion of saturated acids were demonstrated.

"The saturated acids are palmitic and stearic acids, together with a small amount of mixed higher acids similar to 'cerotic acid', which may have been derived from wax esters. The presence of α -linolenic acid was proved by bromination and oxidation, and of α -linoleic acid by oxidation. Thiocyanometric analysis suggests the presence of oleic or an isomeric octadecanoic acid, but no confirmatory evidence could be obtained by oxidation experiments.

"The thiocyanometric method of analysis is discussed in some detail, and the conclusion drawn that it may give misleading results in the case of mixed fatty acids containing large amounts of the so-called β -linoleic and β -linolenic acids. The mixed fatty acids from grasses are of this type."

The composition of whites, yolks, and whole eggs broken out by commercial egg-breaking establishments, L. C. MITCHELL, S. ALFEND, and F. J. McNALL (*Jour. Assoc. Off. Agr. Chem.*, 16 (1933), No. 2, pp. 247-255).—The U.S.D.A. Food and Drug Administration presents a tabulation of the analyses of a large number of samples in terms of solids, total nitrogen, and water-soluble nitrogen in the whites, and of solids, fats, phosphoric anhydride, total nitrogen, and water-soluble nitrogen in the yolks, and with these data the source, manufacturer, and the collection date of the samples.

Occurrence of sulfur, organic matter, nitrogen, and water in phosphate rock, W. L. HILL, H. L. MARSHALL, and K. D. JACOB (*Jour. Assoc. Off. Agr. Chem.*, 16 (1933), No. 2, pp. 260-276).—This contribution from the U.S.D.A. Bureau of Chemistry and Soils presents results of determinations of total sulfur, acid-soluble and acid-insoluble sulfate, and acid-soluble and acid-insoluble sulfide in 26 samples of domestic rock phosphate of commercial grade from

various localities, 2 samples of phosphatic limestone, and 2 samples of North African phosphate. Sulfur was found in all samples analyzed.

The organic carbon, as determined by dry combustion of the rock, was used as a standard measure of the amount of organic matter present in the phosphates. In addition, comparative data were obtained by determining organic carbon by dry combustion of the organic material actually separated from the rock, organic matter by a colorimetric control method, and organic matter and water by calculation from the ignition loss. Quantitative data on the several factors which affect the ignition loss are also given. Organic carbon, nitrogen, and total water were determined in 29 samples of natural phosphates from various deposits in the United States and elsewhere. Large-scale separations of the organic material were made on several types of phosphate rock, and the isolated materials were analyzed for carbon, hydrogen, nitrogen, and sulfur.

The adsorption of electrolytes by ash-free charcoal.—VII, A brief survey of the present status of the subject, and evidence that negative adsorption of inorganic bases decreases with length of time of contact of charcoal with solution, E. J. MILLER (*Jour. Phys. Chem.*, 36 (1932), No. 12, pp. 2967-2980, figs. 5; *abs. in Michigan Sta. Quart. Bul.*, 15 (1933), No. 4, pp. 303, 304).—This contribution from the Michigan Experiment Station (E.S.R., 65, p. 412) is continued, with a presentation of data indicating that negative adsorption of alkali decreases with length of time the charcoal is in contact with the solution; that charcoal must be heated at approximately 1000° or above to produce negative adsorption from solutions of sodium hydroxide; that it is practically impossible to remove even a feebly adsorbed acid such as hydrochloric from charcoal by repeated extraction with boiling water; and that adsorbed hydrochloric acid can be quantitatively removed from charcoal by electrodialysis.

"No one theory alone seems capable of explaining satisfactorily all the known facts of adsorption of electrolytes by adsorbent charcoal."

Micro analytical methods, E. P. CLARK (*Jour. Assoc. Off. Agr. Chem.*, 16 (1933), No. 2, pp. 255-260, figs. 3).—The general advantages of such methods, the development of a suitable balance, and the determinations of carbon and hydrogen, of nitrogen, of the halogens, and of the methoxyl group are discussed. A point emphasized, in addition to that of the entirely satisfactory grade of accuracy of these methods and their applicability to relatively minute quantities of material, is the economy effected by the introduction of micro methods even in routine and control work.

A micro conductance cell, H. L. WHITE (*Jour. Biol. Chem.*, 99 (1933), No. 2, pp. 445-449, fig. 1).—Of the apparatus of which the description and a drawing are given it is noted, in part, that "the only materials with which the liquid under investigation comes into contact are glass and the electrodes. Transfer of the liquid from the containing pipette into the capillary cell is easy, and all possibility of evaporation is avoided. . . . Cleaning the cell and replatinizing the electrodes are simple procedures. The cell can conveniently and safely be immersed in a constant temperature bath. The resistance even with very small amounts of biological fluid is relatively high." The avoidance of some difficulties of construction noted in the making of certain earlier conductance cells is pointed out.

The determination of colloid osmotic pressures in small quantities of fluid, R. M. HILL (*Jour. Biol. Chem.*, 99 (1933), No. 2, pp. 323-325, fig. 1).—An osmometer of but 0.3 cc capacity is shown. Equilibrium could be attained in from 1.5 to 2.0 hours when the osmotic pressure was not over 100 mm of water. A gum arabic solution giving an average reading of 253 mm reached equilibrium

in 3.6 hours. The results agreed well with those determined in apparatus requiring larger volumes and a longer time for the establishment of equilibrium.

Study on collodion membrane filters, I, II, I. ASHESHOV (*Jour. Bact.*, 25 (1933), No. 4, pp. 323-337, figs. 2; 339-357, figs. 5).—The author prefers collodion filter membranes to bacteriological filters of the porous porcelain type because of the relative freedom of the collodion film from adsorptive tendencies, the greater ease with which, and range within which, the porosity may be varied, the fact that their retention of particles above a given size is due directly to the size of the pores rather than to the intricacy of the channels (as in porcelain filters) through which the filtrate must pass, so that micro-organisms cannot grow through porosities through which they would not flow, etc. It is also noted that "the electro-negative corpuscles, if retained, lie on the surface of the membrane only and not in the pore channels. Collodion filters thus have two great advantages from the technical point of view: (a) The sediment on the membrane can be collected with very little loss, and (b) the filters can be very easily cleaned and thus can recover a great part of their filtering capacity."

The two papers take up in some detail preparation of graduated membranes, collodion sacs, membrane filters, material for use, stock solution of collodion, preparations of membranes, manipulations of the membrane filters, measurement of permeability, influence of ingredients on the properties of membranes, and the use of membrane filters.

Note on the use of sinalbin as an indicator, K. HARRISON (*Biochem. Jour.*, 26 (1932), No. 1, pp. 88, 89).—Sinabin, a glucoside of *Sinapsis alba*—obtained by first extracting the oils of the ground seed thoroughly with carbon disulfide, then boiling the air-dried oil-free residue (200 g) from 400 g of the ground seed with 500 cc of 95 percent alcohol for 30 minutes, filtering hot, and bringing about the crystallization of the glucoside by chilling the filtrate in ice water—was found to change from colorless at pH 6.2 to an intense yellow at pH 8.4, and to show but small salt and protein errors. With potassium chloride of a concentration below 0.38 N no salt error was observed; in 0.38 N potassium chloride the salt error became +0.02 pH unit; in 0.46 N, +0.06; and in 0.54 N, +0.15. The protein error introduced by a 2 percent casein solution was -0.09, by 2 percent "natural egg white", +0.03, by 4 percent ox blood serum, 0.04. The indicator was found suitable for the titration of weak acids and bases, including ammonia.

Determination of calcium in mineral mixtures, V. W. MELOCHE, L. E. CLIFCOEN, and W. B. GRIEM (*Jour. Assoc. Off. Agr. Chem.*, 16 (1933), No. 2, pp. 240-245).—A method dependent for its improved accuracy upon carrying out the initial precipitation of calcium oxalate in a strongly acid solution—a procedure shown to be of importance especially when the sample contains phosphorous compounds—is described and compared with the Official method in a contribution from the University of Wisconsin. The effect of the presence of magnesium and iron as well as that of phosphorus upon the results yielded by the proposed and by the Official method was determined.

Volumetric method for determination of fluorine, H. H. WILLARD and O. B. WINTER (*Indus. and Engin. Chem., Analyt. Ed.*, 5 (1933), No. 1, pp. 7-10; *abs. in Michigan Sta. Quart. Bul.*, 15 (1933), No. 4, p. 303).—A method for titrating soluble fluoride and silico-fluoride solutions with standard thorium nitrate, using a zirconium-alizarin mixture as indicator, is described. A method for the volatilization of fluorine as hydrofluosilicic acid and the titration of the fluorine in the distillate gave theoretical results in the absence of a large amount of gelatinous silica. Materials which could not be decomposed by perchloric acid required to be fused with sodium carbonate before the fluorine could be volatilized as hydrofluosilicic acid. A method for removing the silica

when a sufficient amount is present to interfere with the volatilization of the fluorine is described. Volatilization of fluorine from certain insoluble fluorides, as silicon tetrafluoride, and determination of the fluorine by titration with thorium nitrate was found to give unsatisfactory results in the presence of plant ash, however. A volatilization of the fluorine as hydrofluoboric acid, with subsequent titration of the fluorine in the distillate, was found to give inconsistent results.

Determination of small quantities of benzyl alcohol, J. CALLAWAY, JR., and R. REZNEK (*Jour. Assoc. Off. Agr. Chem.*, 16 (1933), No. 2, pp. 285-289).—A study of the physical properties of benzyl alcohol and of the conditions under which its oxidation to benzoic acid might be used as a means of determining the alcohol is reported in this contribution from the U.S.D.A. Food and Drug Administration, and methods for determining the alcohol (1) from the specific gravity and immersion refractometer readings and (2) by oxidizing the alcohol to benzoic acid, extracting with chloroform, and titrating the isolated acid, are prescribed.

Rapid methods of examining soils, II, III, R. K. SCHOFIELD (*Jour. Agr. Sci. [England]*, 23 (1933), No. 2, pp. 252-260).—These two papers, continuing the general subject of the previous contribution (E.S.R., 68, p. 446), take up two applications of buffer solutions as means of effecting soil analyses.

II. *The use of p-nitrophenol for assessing lime status* (pp. 252-254).—In the method described use is made of the fact that paranitrophenol half neutralized with calcium hydroxide forms aqueous solutions strongly buffered at pH 7.1. Saturated lime water sufficient to make the final solution N/25 with respect to calcium is placed in a 1-l volumetric flask, 8.34 g of paranitrophenol is added and dissolved, and the volume is made up to 1 l. In this reagent two thirds of the paranitrophenol is neutralized. The remaining procedure is thus described:

"When it is anticipated that something less than 8 mg equivalents of lime will be taken up per 100 g of soil, 8 g of the air-dry soil are placed in a 50 cc boiling tube and 40 cc of the solution is added. After an overnight period in a shaker, it is filtered, care being taken to avoid evaporation, and 25 cc is titrated with N/20 HCl, using bromocresol green as indicator. The titration is taken to the point at which the green color has almost disappeared. The flask in which the titration was done is set on one side, and 25 cc of the original solution titrated to the same color. This can be done to one drop. The difference in cubic centimeters between the two titrations equals the milligram equivalents of lime taken up per 100 g of soil. . . .

"It is not essential to have the soil continuously shaken with the solution for 16 hours, but it is important to have a contact of at least this duration, especially in the case of organic soils. A gentle shaking somewhat improves the reproductibility. With a longer contact, a little more lime is usually taken up. Sixteen hours does not, therefore, give a final figure, but is convenient, since a variation of an hour or so does not materially influence the result. When the lime uptake is large, duplicates usually fall within 2 percent of the mean, or within 0.2 mg equivalents where it is small."

III. *The use of dihydrogen potassium phosphate in studying base exchange capacity* (pp. 255-260).—The reduction in the electrical conductivity of a mixed solution of K_2HPO_4 and KH_2PO_4 , caused by the addition of soil was found to constitute a measure of the potassium uptake, and to furnish, therefore, an indication of the "base exchange capacity" of the soil at pH 7. Two disturbing factors were noted, however, and it is concluded that the method is likely to be most useful where a rapid comparison of soils of a similar nature and pH is required.

Of the two disturbing factors, the first, namely, the slightly lower mobility of the dihydrogen phosphate ion as compared with the monohydrogen phosphate ion, was found to introduce "on an average, an error of scarcely more than 1 percent." The second source of discrepancy, that is, the action of the soil in exchanging calcium or magnesium for potassium had, however, an effect such that "the fractional change in conductivity has to be increased by about 14 percent to obtain the fractional change in potassium concentration." Of this finding, it is noted that "with a set of calcareous soils this 14 percent correction might be applied, but where the figures are only to be compared one with another, no real purpose would be served. In general, a separate measurement would be needed to decide the amount of the correction, so that for the present it seems best to use the figures obtained in the way indicated above as they stand."

A comparison of field methods for determining the available phosphorus of soils, C. A. ENGBERG and C. H. SPURWAY (*Jour. Amer. Soc. Agron.*, 25 (1933), No. 5, pp. 354-360).—This contribution from the Michigan Experiment Station reports comparative determinations made by means of four soil phosphate methods as to the phosphate requirements of two experiment fields each on the Roselawn and Onaway sandy loam soils, of three fields located on Isabella sandy loam, and of one field on Fox sandy loam.

"The results from the Illinois phosphate test [E.S.R., 62, p. 13] showed a poor correlation with the crop response of the soils to phosphatic fertilizer treatments. The test showed very little difference between soils deficient in phosphorus and those containing a large amount of available phosphorus as judged from fertilizer applications and crop yields. The Illinois phosphate test as used in this research has shown a tendency to show phosphorus deficient plats as indicated by crop response to phosphatic fertilizer as high in phosphorus. The limiting value of phosphorus in this test in most cases could be established as medium. Very few 'low' or 'doubtful' soils were found by the use of this method. The results from the LaMotte-Truog method showed a fair agreement with the crop response to phosphatic fertilizers. The results from Truog's laboratory method [E.S.R., 64, p. 312] showed a fair correlation to the crop response of the soil to phosphatic fertilizers. However, when large amounts of phosphorus were present in the soil as indicated by the LaMotte-Truog method and fertilizer applications, Truog's laboratory method did not indicate these large amounts. Only one standard is used in this method, and that may account for this variation due to the wide difference between the depth of color developed by the standard and the unknown. Because of this wide variation it is not possible to read as accurately when large amounts of phosphorus are present. The results obtained by Spurway's water-soluble phosphorus method [E.S.R., 62, p. 12] agreed fairly well with the results obtained by the use of phosphatic fertilizers.

"The limiting values as established by the LaMotte-Truog method, Spurway's water-soluble phosphorus method, and Truog's laboratory method agree quite well with the results obtained in this study. The LaMotte-Truog method and Spurway's water-soluble phosphorus method could both be recommended as field methods of determining phosphorus-deficient soils under Michigan conditions. Truog's laboratory method could be recommended for use in the laboratory to determine the available phosphorus of soils, although it is not as rapid as the LaMotte-Truog method and Spurway's water-soluble phosphorus method."

Determination of ammoniacal nitrogen in fertilizers without distillation, Z. I. KEATZ, F. J. KOKOSKI, and A. W. CLARK (*Jour. Assoc. Off. Agr. Chem.*, 16 (1933), No. 2, pp. 233-240).—A contribution from the New York State

Experiment Station reports that ammonia in pure ammonium salts and ammonium fertilizers may be determined without distillation by replacing the ammonium in the salts by alkali metals. The ammonia replaced by the alkali is driven off in a short time by boiling, and the excess of alkali is then measured by titration with standard acid. This method gave good results in the cases of pure ammonium salts and ammonium sulfate fertilizers, although the results for other ammonium fertilizers were somewhat more divergent than those obtained in the case of ammonium sulfate. "The chief advantage of the method is that results may be obtained in much shorter time than by the usual distillation method." Working details are given, and a tabulated statement of experimental results is included.

Nitrogen changes in stored alcoholic extracts of plant tissues, J. E. WEBSTER (*Plant Physiol.*, 8 (1933), No. 1, pp. 166-168).—Using the Van Slyke method for determining the amino nitrogen as affected by various periods and conditions of storage, and an aeration method for estimating the ammonia formed, the author of this contribution from the Oklahoma Experiment Station determined some effects of reaction, time of storage, percentage of alcohol, the presence of minerals, etc., on stored alcoholic extracts of plant tissues. He reached the conclusion that reaction is probably the most important chemical factor, extremes of acidity and alkalinity inducing the largest changes recorded; and that length of time in storage is an important factor, equilibrium being reached in 1 year only in exceptional cases. The most extended period considered experimentally was $2\frac{1}{2}$ years, at the end of which time "equilibrium seemed to have been reached in the solution."

With reference to the nature of the changes recorded it is pointed out that "in a few of the experiments recorded there is enough of an increase in ammonia to account for the decrease in amino nitrogen. Generally, however, the decrease in amino nitrogen is greater than can be accounted for by the increased amount of ammonia. In the case of a synthetic solution, the decrease of amino nitrogen was roughly 10 times the increase in ammonia." The occurrence of condensation reactions between either amino acids or ammonia and compounds (e. g., aldoses) having available aldehyde groups is suggested as a tentative explanation of the disappearance of amino nitrogen in excess of the ammonia formed, and some possible reactions of deamination and condensation are very briefly discussed.

The estimation of glutamine in the presence of asparagine, A. C. CHIBNALL and R. G. WESTALL (*Biochem. Jour.*, 26 (1932), No. 1, pp. 122-132).—The early observation that glutamine reacts abnormally with nitrous acid was confirmed in the course of the experiments reported, 92 percent of the total nitrogen of glutamine having been shown to react as if it were amino nitrogen in the Van Slyke apparatus. The stability of glutamine in solution at 100° at various pH values was investigated, both amide N and amino N being determined. After heating at 100° at pH 8 for 3 hours, glutamine gave 35 percent of the total N as amide N, while the amino N fell to 8.5 percent. Asparagine was shown to be stable under these conditions.

"This difference in behavior has been made the basis of a method for the separate determination of asparagine and glutamine in plant extracts," a procedure which was successfully applied to a mixture of asparagine and glutamine and also to six plant extracts of which the amide contents were known.

The isolation of asparagine from an enzymic digest of edestin, M. DAMODARAN (*Biochem. Jour.*, 26 (1932), No. 1, pp. 235-247).—A digestion of edestin nearly complete and accompanied by but little separation of amide nitrogen was shown to be attainable by subjecting the protein successively to the action of pepsin, trypsin, and yeast dipeptidase.

"Complex polypeptides, bases, dicarboxylic acids were removed from the digest by appropriate reagents and the resulting solution fractionally crystallized. From one of the crystal fractions asparagine was isolated and its presence in the protein molecule thus definitely established. To attempt to crystallize glutamine was unsuccessful, but its presence in the digest was demonstrated indirectly by the method of Chibnall and Westall" above noted.

Determination of arsenic in plant materials, R. B. DEEMER and J. A. SCHRICKEK (*Jour. Assoc. Off. Agr. Chem.*, 16 (1933), No. 2, pp. 226-232).—The authors of this contribution from the U.S.D.A. Bureau of Chemistry and Soils found the recovery of arsenic from pure solutions to be complete when either the arsine evolution method or a suitable molybdenum blue reagent was used. This procedure, however, was not found to be adapted to solutions obtained by the wet ashing of plant materials. "When used with the arsenic trichloride distillation method this [molybdenum blue] colorimetric method gives good recoveries from wet ashed samples. This method is applicable to quantities of arsenic pentoxide ranging from 0.002 mg to 10.0 mg. Above 10.0 mg dilution errors enter. As no more than 0.200 mg in 50 cc is readable, the corresponding dilution of 50 to 1 for 10.0 mg reduces precision accordingly." Manipulative detail is fully described.

Qualitative detection of lead in spray residues. M. HARRIS (*Jour. Assoc. Off. Agr. Chem.*, 16 (1933), No. 2, pp. 245, 246).—The proposed method from the U.S.D.A. Food and Drug Administration, Chicago, Ill., is based on the turbidity formed on the addition of sodium bisulfite to a slightly acid or neutral solution of lead. A positive test was obtained with 0.1 mg of lead oxide when the method outlined below was used. "However as a matter of precaution 0.15 mg was used." To obviate the chance of false conclusions which might be caused by the presence of barium and strontium, the presence of lead was confirmed by conversion of the sulfite to the iodide by means of a potassium bromide-potassium iodide solution, with a subsequent microscopic identification of the lead iodide.

It was observed that the presence of foreign and organic matter interfered with the formation of the turbidity and lead iodide plates. This difficulty was eliminated by evaporating the wash solution to dryness, leaching out the lead salt with hot water, and filtering. The bisulfite was then added to the clear filtrate. The volume of wash solution that would contain about 0.15 mg of lead oxide was estimated from the previously determined arsenic value by assuming the ratio of PbO to As_2O_3 in arsenical spray residue to be 2.5 to 1.

Determination of iron in milk and other biological materials, R. STUGART (*Indus. and Engin. Chem., Analyt. Ed.*, 3 (1931), No. 4, pp. 390-393).—The author found the colorimetric method dependent upon ferrocyanide inapplicable in the cases of samples containing appreciable quantities of phosphorus and of calcium. That form of the thiocyanate method in which the ferric thiocyanate is extracted with amyl alcohol gave reliable results, but color comparison in aqueous solutions was inaccurate because of fading, either extraction was unsatisfactory, and the use of acetone as a solvent failed to prevent fading. The iron content of milk could not be determined with sufficient accuracy by either gravimetric or volumetric methods. Methods requiring the use of large quantities either of potassium or of sodium hydroxides could not be applied because of the impossibility of freeing either of these reagents sufficiently completely from iron compounds or of determining their iron content accurately enough to permit the use of a correction. Methods using only small quantities of alkali were also unreliable because of iron in the sodium hydroxide and of that dissolved during heating from the glass.

A method eliminating alkali treatment entirely was therefore elaborated, and its working detail is fully stated.

Determination of inactive malic acid in fruits and fruit products, B. G. HARTMAN and F. HILLIG (*Jour. Assoc. Off. Agr. Chem.*, 16 (1933), No. 2, pp. 277-285).—Procedure for the determination of inactive malic acid in fruits and fruit products, presented in this contribution from the U.S.D.A. Food and Drug Administration, involves (1) isolation of total malic acid (levo and inactive modifications), (2) determination of the total malic acid by oxidation with potassium permanganate in alkaline solution, and (3) determination of the inactive malic acid by subtracting the levo acid obtained polarimetrically from the total malic acid. "The procedure is easy to follow, but it is time-consuming. In the interpretation of the results obtained by the method it is necessary to make a correction of 0.01 percent."

Determination of uronic acids and methoxyl in certain plants and plant materials, M. PHILLIPS, M. J. GOSS, and C. A. BROWNE (*Jour. Assoc. Off. Agr. Chem.*, 16 (1933), No. 2, pp. 289-292).—The authors of this contribution from the U.S.D.A. Bureau of Chemistry and Soils present a brief account of work described as of a preliminary nature on the determination of the uronic acids present in food plants on the basis of the reaction of these acids with boiling 12 percent hydrochloric acid to give furfural and carbon dioxide. A quantitative yield of the furfural could not be obtained in the distillation, but the carbon dioxide yield was quantitatively measurable if the sample were first heated at 70° C. with the acid for a half hour to decompose any carbonates present, and then aerated with carbon dioxide-free air for 20 minutes. No decomposition of the uronic acids took place at 70°. This decomposition was effected by heating in an oil bath maintained at from 135° to 140° for 5 hours, and a small stream of carbon dioxide-free air carried the evolved gas into a known volume of 0.2 N barium hydroxide in an absorption tower. From such data uronic acid contents of from 3.60 to 17.72 were determined in various plant materials.

The influence of manufacturing operations upon the microbial content of grape juice, F. W. FABIAN (*Fruit Prod. Jour. and Amer. Vinegar Indus.*, 12 (1933), No. 5, pp. 141, 142; *abs. in Michigan Sta. Quart. Bul.*, 15 (1933), No. 4, p. 304).—A process for the complete commercial sterilization of grape juice and for its safe storage is detailed.

Faulty pasteurization responsible for moldy grape juice, F. W. FABIAN (*Fruit Prod. Jour. and Amer. Vinegar Indus.*, 12 (1933), No. 6, pp. 173-175, 188, fig. 1; *abs. in Michigan Sta. Quart. Bul.*, 15 (1933), No. 4, p. 304).—A hot water rinsing of the commercial equipment for the handling of grape juice failed to sterilize the system, leaving principally yeasts with some molds. A momentary heating to 150° F. before bottling appeared to sterilize the juice. An exposure to a temperature of 180° for 37 minutes after bottling and capping prevented spoilage of the bottled product.

AGRICULTURAL METEOROLOGY

Meteorological data: Progress report of special committee, D. M. BAKER ET AL. (*Amer. Soc. Civ. Engin. Proc.*, 59 (1933), No. 1, pp. 153-182, figs. 9; *abs. in Bul. Amer. Met. Soc.*, 14 (1933), Nos. 4, pp. 111-114; 5, pp. 135-142).—This is a report of a committee of the American Society of Civil Engineers, appointed in April 1931, to "give thought as to how the United States Weather Bureau could be made of greater service to engineers." The report contains numerous criticisms, suggestions, and recommendations looking toward possible improve-

ment of the scope, quality, and usefulness of the work of the Bureau, especially from the engineer's viewpoint.

Microclimatology [trans. title], R. GEIGER (*Naturwissenschaften*, 21 (1933), No. 5-7, pp. 132-137, figs. 7; *abs. in Sci. Abs., Sect. A—Phys.*, 36 (1933), No. 425, p. 449).—Reference is made to the many influences of small changes of climate from one place to another on plants, small animals, and insects and to the importance of such changes in selecting sites for sanatoria, hospitals, and dwelling houses. The effects of town dust on nocturnal temperature inversions and cloudiness and of streets and public squares on temperature changes are also discussed.

Radio Research Board: Report No. 5, Atmospherics in Australia, I, G. H. MUNRO and L. G. H. HUXLEY (*Aust. Council Sci. and Indus. Res. Bul.* 68 (1932), pp. 49, figs. 13).—While this paper deals primarily with an investigation of the atmospherics which interfere with radio reception in Australia, it discusses briefly the utility of the observations on atmospherics for weather forecasting and other matters of broader interest, the conclusion being reached that "a suitably arranged system for observing atmospherics would be of considerable assistance in meteorological work, particularly for weather forecasting, in Australia and in New Zealand."

SOILS—FERTILIZERS

[**Soil investigations of the Nebraska Station**] (*Nebraska Sta. Rpt.* [1932], pp. 14, 15).—Extending the record (E.S.R., 67, p. 505) of its soil work, the station reports briefly upon the relation of weather, cultural practices, and soil conditions to nitrification in Nebraska soils; factors which affect the tilth of soils; and the use of phosphate fertilizer for the irrigated sections of eastern Nebraska.

A microbiological study of podsol soil profiles, P. H. H. GRAY and N. B. McMASTER (*Canad. Jour. Res.*, 8 (1933), No. 4, pp. 375-389, figs. 2).—Microbiological studies of samples from the separate horizons and from different depths of soils of the Appalachian upland podsol group show that the activity of the micro-organisms is dependent upon the organic matter relations in the several horizons. The organic matter horizon was biologically the most active, as shown by analyses for carbon dioxide, nitrate nitrogen, numbers of bacteria, and production of ammonia for urea. Evidence indicating that the reduced activity of the leached layer and the horizons of accumulation is not due to toxic compounds produced by leaching of the organic matter is submitted. The paper is a contribution from McGill University.

Some relationships between water plants and water soils in Michigan, J. O. VEATCH (*Mich. Acad. Sci., Arts, and Letters, Papers*, 17 (1933), pp. 409-413, pls. 2; *abs. in Michigan Sta. Quart. Bul.*, 15 (1933), No. 4, p. 302).—From about 300 observations widely distributed over the water-covered areas of Michigan, a range of pH from 6 to 9.2 was found, and a hardness of water expressed in grains per U.S. gallon from 1.5 to 20. The types of lake "bottoms", or subaqueous cumuloose horizons, were recognized. The most prolific growth of attached plants appeared on the soft, slimy, sedimentary peat bottoms and on the clayey muds; the least growth on the sand, cobbles, and hard bed rock. The conclusion was reached that most of the aquatic plants observed grow under a wide range of soil conditions, but few are limited to certain soil conditions, as, for example, Chara, to waters which are definitely alkaline in reaction and high in calcium.

"The observations made support a theory that many of the present acid or soft water lakes and bogs, covered with acid tolerant plants, were originally alkaline, or hard water lakes, and the change to the acid conditions has been brought about by filling of the lakes with vegetation to a point where only a small depth of water remains. At this point acid tolerant plants may gain a foothold and convert the area into an acid bog or an acid peat swamp."

The diffusion of carbon dioxide through soils, F. B. SMITH and P. E. BROWN (*Soil Sci.*, 35 (1933), No. 6, pp. 413-423, pl. 1, fig. 1).—In the investigation reported upon in this contribution from the Iowa Experiment Station the diffusion of carbon dioxide through moist soil was found to be complicated to such a degree by the production of carbon dioxide in the soil while the measurements were being carried out that an accurate determination of the rate of diffusion could not be made. "This no doubt explains why Buckingham found diffusion to be an exponential function of porosity and concluded that diffusion was not influenced to any great extent by moisture, texture, and structure." These factors were found to influence the rate of diffusion in so far as they affect porosity; and an effort was made to estimate the amount of carbon dioxide produced during the experiment and correct for it in the calculation of the diffusion coefficient. This variable was finally eliminated, however, by using air-dry soil, and more than 100 experiments were made, using air-dry soils differing in porosity. It was concluded from the data obtained that the rate of diffusion of carbon dioxide through air-dry soil is a linear function of porosity of the soil within the limits of porosity studied. "This does not mean, however, that at zero porosity, that is, soil saturated with water, that there would be no diffusion of carbon dioxide through the soil; nor that at 100 percent porosity, that is, free diffusion, this relation would hold."

The diffusion of carbon dioxide through Carrington loam in situ was determined 11 times over a period of about 5 weeks. The results obtained varied from 2.535×10^{-3} to 32.750×10^{-3} . "Since the method is subject to certain inaccuracies, caution must be observed in the interpretation of the data. However, since it is a resultant of many forces, some of which are related to the production of carbon dioxide in the soil, it would seem to be a better index of the amount of carbon dioxide produced in soils in situ than either the concentration of carbon dioxide in the soil air or the evolution of carbon dioxide from the soil alone."

Soil organic matter, R. R. McKIBBIN (*Jour. Amer. Soc. Agron.*, 25 (1933), No. 4, pp. 258-266, fig. 1).—The physical, chemical, and biological importance of soil organic matter is emphasized. "Most Quebec soils, fertile and infertile, contain large amounts of nitrogen and organic carbon in their surface few inches in an acid state." Several groups of Quebec soils were differentiated, their properties are briefly discussed, and average and extreme analyses reported. Physical and chemical treatments, through the practical application of which it is hoped to modify favorably the organic matter resources of the most extensive soil group discussed, namely, the Appalachian upland podsol soils, are mentioned.

Influence of chemical composition of organic matter on rate of decomposition, T. L. MARTIN (*Jour. Amer. Soc. Agron.*, 25 (1933), No. 5, pp. 341-346).—The author reports that the results of his experiments agree with the findings of Tenney and Waksman (*E.S.R.*, 62, p. 414) and others, except that the sweetclover cellulose did not break down nearly as readily as did the crude protein. The water-soluble materials in the roots and tops disappeared rapidly and at about the same relative rates for organic material from the

same source, but the disappearance was more rapid for alfalfa than for sweetclover. Alfalfa tops and roots seemed to decompose more rapidly than did sweetclover tops and roots. The lignin content accumulated very rapidly, more so in the case of roots than in that of tops. "Due in all probability to a higher percentage of lignin in the roots and to its tendency to arrest decay of cellulose, tops decompose at a more rapid rate than do the roots. Because of the slow decomposition of proteins and the rapid accumulation of lignin, there is the suggestion that the remainder will consist largely of these two substances. However, in the sweetclover tops and roots cellulose probably too will be a part of the residue."

The iodine content of the soil in Kentucky, J. S. MCHARGUE and D. W. YOUNG (*Soil Sci.*, 35 (1933), No. 6, pp. 425-435, fig. 1).—Samples of soil from the six principal geological areas in Kentucky were analyzed for iodine. The largest quantities were found in soils derived from limestone strata, while the smallest quantity occurred in the soils derived from sandstone strata in the Eastern Coal Field area. It appeared that the foods and natural waters produced in some parts of the Eastern Coal Field may be deficient in iodine to the extent that endemic goiter is more likely in this part of the State than in any other part. The soils of the Western Coal Field area were found to contain nearly twice as much iodine as those of the Eastern Coal Field. The iodine content of the Maury (phosphatic) and Mercer (nonphosphatic) soil profiles in Fayette County showed considerable variation at different depths. There was no correlation between the phosphorus and iodine content in the two profiles. Soils derived from limestone rocks appeared to contain considerably more iodine than the unaltered rock.

Soil rebuilding at the Red Plains Erosion Station, S. W. PHILLIPS (*Jour. Amer. Soc. Agron.*, 25 (1933), No. 5, pp. 346-350).—The experiments reported upon have been carried out cooperatively by the U.S.D.A. Bureaus of Chemistry and Soils and of Agricultural Engineering, working with local agencies. The investigation included work at this station, near Guthrie in central Oklahoma, on erosion and run-off rates and fertility losses, on vegetational and other means of control, and on the reclamation of eroded soils.

A continuous cotton plat lost four times as much soil as did a plat in sweetclover, cotton, and wheat rotation. A Bermuda grass plat lost only about 2 percent of the precipitation moisture and almost no soil. A fallow plat, though it lost about twice as much moisture, lost about 10 percent less soil than did a corresponding cotton plat. Cotton on clay subsoil about doubled the run-off and erosion loss of cotton on topsoil.

Closed-end terraces in Vernon fine sandy loam saved much moisture but caused standing water damage to the crop on the terraced channels, while graded terraces effected no considerable saving of moisture and were of practical effectiveness only for soil conservation.

Of certain of the experiments on erosion control through cropping practices, the following statements are made: "Four 1-acre fields (4 percent slope) were put into strip cropping this year. The cotton was listed (bedded) in on the contour, and the thick-growing, soil-saving strips were planted to oats and Sudan grass. The row crop and soil-saving strips each occupy approximately half of the land. With one of the most intense rains (May 31, 1932) since the establishment of this station, it was observed that this method of farming almost completely stopped soil losses and very largely diminished run-off. . . . Bermuda-grass dams have proved effective in the control of small gullies, but some farmers object to starting this persistent grass anywhere on their lands. With light application of superphosphate sweetclover has caught very well in

an experiment dealing with a large gully, and shows promise of being a useful implement in controlling these major ravines. Subsoiling has not as yet shown any profitable increase in yields, but the experiments are being continued in order to determine definitely the full significance of this tillage method."

The Winogradsky spontaneous culture method for determining certain soil deficiencies, A. W. YOUNG (*Iowa Sta. Res. Bul. 157 (1933), pp. 24, fig. 1*).—Soils from 21 experimental plats on Carrington loam at the Agronomy Farm, 3 samples of soil from each of 9 outlying experimental fields located on various soil types, 2 samples of soil from Colorado, and 1 soil from Utah were tested for phosphorus deficiency by the spontaneous culture method (E.S.R., 66, p. 616). Starch, mannitol, and glucose were compared as energy sources for the development of the spontaneous cultures on the soil plates; experiments were conducted on the inoculation of soils which did not support spontaneous culture growth; and some of the phosphorus relationships of the spontaneous culture development on the soil plates were studied.

From the results recorded, it would seem "evident that the spontaneous culture test is of little value for determining the phosphorus deficiencies of the Iowa soils tested. There seems to be little possibility of modifying the test to make it of use for this purpose, since many of the soils of Iowa are too acid to permit the growth of the organisms responsible for the spontaneous cultures. It is also questionable whether this test would indicate the amounts of phosphorus which would produce the maximum economic crop yields when applied to the soils of Iowa."

Soil plates made from acid soils could be made to yield spontaneous cultures by neutralizing the soil with calcium carbonate, adding mannitol and phosphate, and inoculating with a pure culture of *Azotobacter*. Either mannitol or glucose stimulated spontaneous culture growth much more than did starch. Mannitol yielded a colony growth of a viscosity much greater than that produced from glucose. Of 17 phosphates substituted for disodium hydrogen phosphate, all appeared more or less available to the organism.

Studies on readily soluble phosphate in soils, I, II, H. W. LOHSE and G. N. RUHNKE (*Soil Sci., 35 (1933), No. 6, pp. 437-457, figs. 4; 459-468, fig. 1*).—The first two papers of a series contributed from the Ontario Agricultural College are here noted.

I. Extraction of readily soluble phosphate from soils by means of dilute acid potassium sulfate ($KHSO_4$).—Readily soluble soil phosphate is defined as the amount of phosphate (expressed as milligrams P per 1,000 g of soil) extracted by shaking 2 g soil (20 mesh) for 5 minutes, with a $KHSO_4$ solution of such a strength that the acidity in the filtered extracts is approximately that expressed by a pH value of 2.00. An acid solvent of this strength proved to be strong enough to extract the readily soluble phosphate in a soil sample; it did not break up the difficultly soluble soil phosphate appreciably; and the acidity of the extract was high enough to prevent reprecipitation of dissolved phosphate. The readily soluble phosphate in a soil sample was adequately removed by 5 minutes of shaking.

The method used for the extraction of readily soluble phosphate from soils by means of dilute $KHSO_4$ solutions at a pH of 2.00 is described in working detail.

II. The vertical distribution of readily soluble phosphate in some representative Ontario soils.—Readily soluble soil phosphate, extracted by 5 minutes of shaking with a $KHSO_4$ solution at a pH of 2.00, varied so much in vertical distribution that surface sampling alone was found inadequate. "In determining the vertical distribution of readily soluble soil phosphate, extraction

at the same pH value in the extracts from all the horizons, is desirable. The extracts must also be at a pH value where reprecipitation of dissolved phosphate is prevented.

"Sandy podsol soils seem to be very low in readily soluble phosphate in all horizons, the parent material included. Clayey podsoles and brown forest soils contained large amounts of readily soluble phosphate in the B horizon and in the parent material. Cultivated soils of the brown forest group contained, in all cases, considerable amounts of readily soluble phosphate in the lower horizons. Extractions of profile samples from typical cultivated brown forest soils, well known as to their fertility, indicate that the extraction method (KHSO_4 method) used gives a good index to the fertility of these soils, as far as their phosphate supply is concerned."

Phosphate availability in alkaline calcareous soils, W. T. McGEORGE (*Jour. Amer. Soc. Agron.*, 25 (1933), No. 5, pp. 351-354).—This contribution from the Arizona Experiment Station reports and discusses chemical and physical relations of plant root and soil solution in alkaline calcareous soils. Data "which quite definitely show that there will be no absorption of phosphate by the roots until the reaction (pH) of the root soil contact zone has been reduced by carbon dioxide exudation to pH 7.6, which is the reaction at which the ratio of H_2PO_4 to HPO_4 ions closely approaches equality," are emphasized, and one of the principal conclusions reached was that the infertility of alkaline calcareous soils takes in large part the form of a nonabsorption of phosphate and possibly of other ions; only to a lesser degree that of a direct alkaline toxicity. "Phosphate availability in such soil types is not a simple matter of solubility, but rather is a complex of several factors to which carbon dioxide is the key. A thorough acquaintance with these factors may be of greater assistance in estimating the phosphate requirement of a soil than a determination of phosphate solubility by means of some empirical reagent."

Nitrogen accumulation in soil as influenced by the cropping system, T. L. LYON and J. A. BIZZELL (*Jour. Amer. Soc. Agron.*, 25 (1933), No. 4, pp. 266-272).—This contribution from the New York Cornell Experiment Station reports upon experiments undertaken for the purpose of determining the apparent fixation of nitrogen in soil of medium nitrogen content on which various cropping systems were followed without nitrogenous fertilizer but with lime, phosphorus, and potassium liberally applied. The surface soil was placed in frames and was sampled and analyzed at the beginning and end of a period of approximately 10 years. Nitrogen was determined in all of the crops produced, and a record of the removal from each of the frames was kept for the entire period. Rain and snowfall were measured and their nitrogen determined monthly during the 10 years. The cropping systems consisted of the continuous growth of alfalfa and of timothy and of 5-year rotations in which alfalfa was grown from 1 to 3 years, timothy for a similar time, and red clover 1 or 2 years. Field peas were grown with oats and hairy vetch with wheat in some of the cropping systems. The other crops used in the rotation were fodder corn, wheat, oats, and rye.

So far as yields of nitrogen in the crops were concerned, those cropping systems that included legumes, especially alfalfa, were outstanding. The more often alfalfa occurred in the rotation, the more nitrogen was contained in the crops. Timothy had the opposite effect. Red clover was not as effective as alfalfa in producing nitrogen in the crops, when grown either once or twice in the rotation. The use of peas and vetch with cereals resulted in increased yields of nitrogen. At the close of the period covered by the experiment, the soil on which legumes were grown either continuously or in alternation with

nonlegumes contained more nitrogen than did soil on which no legumes were grown. The more frequently alfalfa occurred in the cropping system, the more nitrogen was contained in the soil at the close of the experiment. Red clover grown in alternation with cereals was more effective than was alfalfa in leaving nitrogen in the soil. The effect of peas and vetch on nitrogen accumulation in the soil was only moderate, whether they occurred once or twice in a round of the rotation.

"Accretion, or what may be termed apparent fixation of nitrogen, was found by adding to the quantity of nitrogen in the crops the gain of nitrogen by the soil, or by subtracting the loss, if such occurred. The nitrogen in rain and snowfall and that in drainage were considered to offset one another." Alfalfa was somewhat more effective in nitrogen accretion than was red clover, and much more so than were peas or vetch. In the case of every cropping system there was apparent fixation of nitrogen whether legumes were grown or not. A rotation of cereals without a hay crop fixed as much nitrogen as did the rotation containing timothy. The average annual accretion of nitrogen in the cropping systems having no legumes amounted to from 20 to 30 lb. to the acre. As no nitrogen was applied in fertilizers and as the soil had a very moderate content of nitrogen the conditions were very favorable for nitrogen accretion. The nature of the crop immediately preceding appeared to be a more important factor in determining the yield of nitrogen in the succeeding crop than was a previous gain or loss of soil nitrogen, at least where such differences were large. The influence of the preceding crop appeared to be exercised through its effect on the availability of soil nitrogen. In the case of alfalfa this effect was found very large.

Soil bacteria and the fixation of atmospheric nitrogen [trans. title], G. DE' ROSSI (In *Atti del IV Congresso Nazionale di Microbiologia, Milano, 1932. Milano: Soc. Internaz. Microbiol., 1932, pp. 15-87*).—The paper is divided into sections dealing with the nitrogen-fixing power of micro-organisms and the sources of error involved, distribution of nitrogen-fixing power among micro-organisms, the *Azotobacter* group, the nitrogen-fixing *Clostridia*, the tubercle organisms of the *Leguminosae*, the nitrogen-fixing activity of the soil bacteria, and practical applications.

Of sources of error in the experimental measurement of the nitrogen-fixing power of micro-organisms the following are regarded as serious: (1) From the air, and especially from that of the laboratory, which cannot conveniently be purified, micro-organisms can take up quantities of nitrogen compounds which cannot be neglected; (2) some culture media contain volatile nitrogen compounds which are assimilated by micro-organisms during their period of growth but are liberated from the controls; and (3) many culture media, especially those prepared from soil extracts, contain nitrates and various organic nitrogen compounds, the nitrogen content of which is undeterminable or imperfectly determinable by customary methods, but will all appear in the organic compounds of the cell plasma after its assimilation by bacteria. It is considered in the highest degree probable that the nitrogen-fixing power attributed by many authors to such of the more common soil organisms as *Hyphomycetes*, *Schizomycetes*, *torulae*, and *algae* is to be explained as an error due to the causes above outlined.

The paper presents also critical summaries of the information thus far made available with reference to the groups *Azotobacter*, *Clostridium*, *Bacillus radiocola*, *Rhizobium*, etc.

Studies on nitrogen absorption from culture solutions.—I, Oats, A. L. STAHL and J. W. SEIVE (*Soil Sci.*, 35 (1933), No. 5, pp. 375-399, figs. 5).—This contribution from the New Jersey Experiment Stations presents, with reference

to the behavior of oats in the solution cultures, the conclusions that "quantitative analyses show that quantity absorption of nitrogen as NH_4 (milligrams per culture per hour) is highest during the earliest period here investigated, gradually declines, and reaches its minimum point at maturity. Quantity absorption of nitrogen as NO_3 (milligrams per culture per hour) shows its minimum point at the earliest period investigated, rapidly increases, and reaches a maximum at the blossoming stage, and then rapidly declines to a secondary minimum with approaching maturity. Quantity absorption of total nitrogen attains a maximum point which corresponds to the point of maximum absorption of nitrogen as NO_3 . This occurs during the flowering period. At no time during the active life cycle was it found that the absorption of nitrogen as NH_4 or as NO_3 entirely ceased.

"Rate absorption of nitrogen as NH_4 (milligrams per gram of dry tissue per hour) is at its maximum during the earliest period here investigated, declines rapidly during the early stages of growth, and reaches a very low minimum rate with approaching maturity. Rate absorption of nitrogen as NO_3 (milligrams per gram of dry tissue per hour) is low during the early stages of development, attains its maximum at the blossoming stage, then declines to a secondary minimum at maturity. The maximum NH_4 rate of absorption of nitrogen is more than double the maximum NO_3 rate. Rate absorption of total nitrogen attains a maximum point which corresponds to the point of the maximum NH_4 rate of nitrogen absorption and is determined by the NH_4 rate. A secondary maximum rate occurs at the blossoming stage, corresponds to, and is determined by, the point of the maximum NO_3 rate.

"Two periods in the growth cycle occur when the plants show higher activity with respect to the rate of nitrogen absorption (milligrams per gram dry plant material per hour) than they do at other periods, the greatest activity occurring at a very early stage and the second period of high activity during the blossoming stage."

Further studies on nitrogen absorption from culture solutions.—II, Buckwheat, A. L. STAHL and J. W. SHIVE (*Soil Sci.*, 35 (1933), No. 6, pp. 469-483, figs. 3).—In continuation of the above, the authors find that in the case of buckwheat, quantity absorption (milligrams per culture per hour) of nitrogen as NH_4 was at its maximum at the beginning of the blossoming period, declined rapidly after blossoming, and was low during the late stages of growth. Quantity absorption of nitrogen as NO_3 was very low up to the beginning of the blossoming period, increased rapidly during the blossoming period, reached a maximum after the blossoming period, and then declined rapidly. Quantity absorption of total nitrogen attained a maximum point which corresponds to the point of maximum absorption of nitrogen as NH_4 at the beginning of the flowering period. Rate absorption of nitrogen as NH_4 (milligrams per gram of dry plant tissue per hour) began with high values, reached a maximum early in the life cycle, and showed low values only during the late stages in the growth cycle. Rate absorption of nitrogen as NO_3 , "is without value" at a very early stage in the cycle, reached a maximum during the blossoming period, then declined very slowly with approaching maturity. The maximum NH_4 rate was approximately six times the maximum NO_3 rate. Rate absorption of total nitrogen attained a maximum point which corresponded to, and appeared to be determined by, the point of the maximum NH_4 rate. The NH_4 rate played a much more important role in nitrogen absorption by the buckwheat plant than did the NO_3 rate, and, during the greater part of the active life cycle, it was the predominating factor in determining the rate of total nitrogen absorption, while the NO_3 rates exceeded the NH_4 rates only in the late stages of the growth cycle, when the rates of total nitrogen absorption were very low.

A comparison of buckwheat with oats, relative to nitrogen absorption, showed that NH_4 nitrogen absorption plays a much more prominent role in buckwheat than it does in oats, while NO_3 nitrogen absorption plays a much more pronounced role in oats than it does in buckwheat.

On the nitrogen fixing micro-organisms of rice soils [trans. title], C. ARNAUDI (In *Atti del IV Congresso Nazionale di Microbiologia, Milano, 1932. Milano: Soc. Internaz. Microbiol., 1932, pp. 96-103*).—The author presents a tabulation of the results of an examination of six fields for cellulolytic aerobes of the *Cytophaga* group, and with reference to the factors limiting the growth of *Azotobacter*. These, with some related experiments, are briefly discussed.

The influence of legume versus non-legume crops on the microbiological activities in the soil.—II, Nitrification and cellulose decomposition, J. E. FULLER (*Soil Sci.*, 35 (1933), No. 6, pp. 485-491).—The present contribution from the Massachusetts Experiment Station, extending the data presented in a previous paper (E.S.R., 64, p. 18), reports that nitrification of ammonium sulfate, dried blood, and the native organic matter by the soil from different plats of an experimental field did not appear to be influenced by the presence of legume or nonlegume crops in the field. The results obtained from soil samples collected in the spring and in the fall did not differ significantly.

Cellulose (oat straw) decomposition in soil from different plats of the field as indicated by the evolution of carbon dioxide, did not appear to be influenced by the presence of legume or nonlegume crops in the field. The evolution of carbon dioxide was greater in the samples collected in the fall than in samples collected in the spring, indicating that cellulose decomposition was more active in the fall.

Nitrogen fixation studies with the soil from different plats of the field gave results comparable with those previously published. Nitrogen fixation did not appear to be influenced by the presence of legume or nonlegume crops in the field.

Nitrification, cellulose decomposition, and nitrogen fixation studied gave results which were in agreement in that there was apparently no influence exerted by the presence of legume or nonlegume crops in the field.

The results of chemical analyses of crops taken from the field, and of the soil from the field, have been published by Morse (E.S.R., 67, p. 367).

Microbiological investigations of grain plats of a single soil under various fertilizer treatments [trans. title], T. CASTELLI (In *Atti del IV Congresso Nazionale di Microbiologia, Milano, 1932. Milano: Soc. Internaz. Microbiol., 1932, pp. 88-96*).—The numbers of gelatin cultivable micro-organisms found in field soil under rational cultivation and fertilizer treatment ranged from 600,000 to 8,500,000 per gram, those of *Azotobacter* from 300 to 10,000 per gram. Cellulose decomposing forms were always found in great abundance. Early spring was found to bring a notable increase in the numbers of micro-organisms cultivable in meat broth gelatin, these including *Azotobacter* and the cellulose decomposing forms. Heavy fertilizer treatment with nitrates depressed the growth of *Azotobacter*, but the repeated addition of small quantities of nitrates or of ammonium salts appeared to favor *Azotobacter* growth. No effect of previous fertilizer treatment on the microbial population of the soil examined could be demonstrated.

Fertilizer experiments on "run-out" hay land, F. S. PRINCE, P. T. BLOOD, T. G. PHILLIPS, and G. P. PERCIVAL (*New Hampshire Sta. Bul.* 271 (1933), pp. 17, figs. 7).—The station has cropped worn-out hay lands successfully to alfalfa by meeting the fertilizer requirements of the crop. Potassium was shown to be the most important plant food requirement, its use increasing the

yield and prolonging the life of the crop. Manuring gave constant and significant increases over a 5-year period. Phosphatic plant food was less needful, and nitrogen less than either potassium or phosphorus. More than 2 tons to the acre of lime was shown to be unnecessary. The pH value did not need for alfalfa to be brought above 5.6 for the production of excellent crops. The spring and summer rainfall had some influence.

These lands needed principally nitrogen for the production of timothy, manuring being of value because of the nitrogen supply. Phosphorus was of value in the first year, but further applications did not appear to be required. Liming benefited the timothy crop.

The soils in question were found upon analysis to be relatively well supplied with nitrogen, phosphorus, and potassium; and "it would appear that worn-out hayfields such as this owe their decline in yield to a lack of available plant food, to a declining supply of rapidly decaying organic matter, and to lessened bacterial activity which would normally render native plant-food stocks available. This condition is doubtless aggravated by high acidity in the soil."

The availability of hydrated lime, limestone, and dolomite of two degrees of fineness, with supplements of red clover hay, as measured by lysimeter leachings, W. H. MACINTIRE, K. B. SANDERS, and W. M. SHAW (*Jour. Amer. Soc. Agron.*, 25 (1933), No. 4, pp. 285-297, fig. 1).—On the basis of the four years' experiments reported upon from the Tennessee Experiment Station, it is considered that "for a soil of good fixing capacity, even without marked acidity, the 100- to 200-mesh fineness of either limestone or dolomite is comparable to an equivalence of hydrated lime, when evaluated by enhanced nitrification and sulfate generation, soluble Ca plus Mg, and repressive effects upon potassium solubility for the 4-year period. The same holds for the 40- to 50-mesh limestone. The 40- to 50-mesh dolomite is not so readily available during the first year, but the disparity is not great. . . .

"Although the total amounts of soluble Ca plus Mg derived from the several dolomite additions were generally comparable to, though slightly in excess of, those found for the corresponding limestone addition, there was a distinct difference in the proportions of the two elements present in the free soil water. This is accounted for not only by marked enhancement of soluble magnesium derived from the dolomite, but also by the diminished outgo of native magnesium where the high-calcic materials were used. The red clover hay increased the outgo of calcium and magnesium, the largest changes being noted during the first year, but this increase was due, primarily, to the amount of soluble calcium and magnesium supplied by the red clover additions. Hence, the addition of green manure did not appreciably increase loss of the Ca plus Mg supplied by the liming materials. As a close approximation, applying to all forms, one fourth of the added liming materials was lost during the 4-year period." It is noted that home ground limestone should be valued on the basis of the 40-mesh fraction.

Seasonal variation of pH in field soils a factor in making lime recommendations, J. B. HESTER and F. A. SHELTON (*Jour. Amer. Soc. Agron.*, 25 (1933), No. 4, pp. 299, 300).—The authors of this note from the Virginia Truck Experiment Station state that seasonal variations of from 0.2 to 2.0 pH units have been observed, and cites differences of 0.47 and of 0.04 pH unit between the July and December values for a soil in its natural condition and for this soil after leaching free of readily soluble salts. It is considered that such differences should be taken into account in making liming recommendations on the basis of pH values.

Retail prices of fertilizer materials and mixed fertilizers, E. E. VIAL (*New York Cornell Sta. Bul. 545* (1932), pp. 157, figs. 53).—Price and plant food relations in fertilizer sales in various parts of the country are analyzed, these and other related data being brought together in tabular and graphic form, some trends having been traced from the year 1882. Among the more general conclusions an important observation was that "for many crops the application of unmixed materials in addition to the regular applications of complete fertilizers has often been recommended. This is not the cheapest method of buying the additional plant food. If the additional plant food is obtained by purchasing higher analysis mixed fertilizers, the added cost would tend to be the wholesale cost of the additional plant food. If the plant food is purchased in unmixed form, the added cost is the wholesale price plus the cost of distribution. If the supplementary application of the unmixed material is considerably more efficient than the application of additional food in the mixed fertilizers, it might pay to follow this method even though the cost of plant food per unit is somewhat higher."

It is also pointed out that "the decline in the general price level since the war has had a disastrous effect on the fertilizer industry."

Inspection of commercial fertilizers for 1932, T. O. SMITH and H. A. DAVIS (*New Hampshire Sta. Bul. 269* (1932), pp. 15).—This is the report for 1932 of the usual fertilizer analyses (E.S.R., 67, p. 115).

AGRICULTURAL BOTANY

How plants get their names, L. H. BAILEY (*New York: Macmillan Co., 1933, pp. VI+209, figs. 12*).—General information is presented on the nomenclature of plants.

Plant material introduced by the Division of Foreign Plant Introduction, Bureau of Plant Industry, [April 1 to September 30, 1931] (U.S. Dept. Agr., Inventories Nos. 107 (1933), pp. 58; 108, pp. 32).—These are the usual descriptive lists of the plant introductions of the Department. A total of 1,946 lots of material is included.

Pollen-tube behavior in Hemerocallis, with special reference to incompatibilities, A. B. STOUT and C. CHANDLER (*Bul. Torrey Bot. Club, 60* (1933), No. 6, pp. 397-416, pl. 1, figs. 7).—Stating that the daylilies (*Hemerocallis*), because they present all degrees of self-fertility from complete incompatibility to strong self-fertility, afford excellent material for the study of pollen tube development, the authors present the results of microscopical studies at the New York Botanical Garden of pollen tube development in various named varieties and species. Three distinct types of pollen tube behavior were observed with relation to incompatibility: (1) The tubes traveled slowly and advanced only a short distance in the stylar canal, (2) the tubes advanced to near or at the open entrance of the ovary and were there inhibited, and (3) the tubes proceeded directly into the ovary, but seeds were rarely formed. On the other hand in crosses there was no case of inhibition of pollen tube development in the upper portion of the style.

Vascular anatomy of the transition region of certain Solanaceous plants, A. F. THIEL (*Bot. Gaz., 94* (1933), No. 3, pp. 598-604, figs. 9).—A report of anatomical studies at the University of North Carolina upon the root-stem transition region in *Solanum tuberosum*, *Lycopersicon esculentum*, and related plants.

Callusing and rooting of cotton stem cuttings, H. E. REA (*Plant Physiol., 7* (1932), No. 4, pp. 733-737; *abs. in Texas Sta. Circ. 68* (1932), p. 31).—A preliminary experiment was completed on a special method of callusing cotton

stems, and a study was made of the relative adaptability of cotton and horticultural plants to propagation by cuttings, in which many of the precallused cotton cuttings were used.

Results obtained with cotton cuttings confirmed those on callusing obtained earlier (E.S.R., 65, p. 817). Under identical conditions the proportion of cotton cuttings striking root was markedly lower than for lilac chaste-tree, Fortune forsythia, pomegranate, Chinese arborvitae, or Vanhoutte spirea. Selection of mature wood seemed important in the winter propagation of cotton cuttings, the soft and medium mature cotton cuttings used in the experiment being worthless. Precallusing of mature cotton cuttings did not prove of value, but dipping the cuttings in paraffin increased slightly the percentage of rooting. The highest percentages of rooting with mature cotton cuttings were secured in an exposed greenhouse bed of quartz sand free of substratum.

The daily growth of Zea mays, W. E. LOOMIS (Amer. Jour. Bot., 19 (1932), No. 10, p. 838).—Young corn plants, according to Iowa State College studies, grow in height only when the temperature exceeds a minimum of about 10° C. (50° F.), and the growing point is well supplied with water. Direct sunlight causes a marked water deficit in the aboveground portions of the plant, even though the roots are liberally supplied with moisture, and quickly stops elongation. However, growth is not checked by light when the light intensity and humidity relations are such that the growing point can obtain a normal supply of water. Well-watered corn grew fastest just before sundown or on warm, cloudy days.

The production of gum by certain species of Rhizobium, D. A. ANDERSON (Iowa Sta. Res. Bul. 158 (1933), pp. 25-56, figs. 2).—The production of gum by various species of *Rhizobium* under different environmental conditions was studied, and efforts were made to determine whether or not gum production would serve to differentiate species.

Preliminary tests showed the gravimetric method used by some investigators for determining the gum content of bacterial cultures to be very slow. Certain organisms produced a marked increase in the viscosity of their solution cultures, while other cultures failed to cause appreciable increases. With high viscosity cultures, the viscosity developed was directly proportional to the amount of gum present in the solution, and viscosity measurements were, therefore, used to determine the relative gum production in solution cultures.

In the cultures tested, the viscosity of solution cultures was found to be entirely unchanged by vigorous shaking, thus indicating that the gum does not form a structure like that present in a gelatine solution, and that the gum probably is an integral part of the solution rather than a capsule around the bacterial cell. Measurable changes in the viscosity of the cultures were not produced by additions of small quantities of acid or alkali.

Whether or not the cultures received a light or heavy inoculation their viscosities were the same at the end of 7 days' incubation, suggesting that for a given concentration of sugar an equilibrium may exist between the amount of gum produced, the quantity of sugar transformed, and probably the number of organisms developing. In certain cultures, the accumulation of gum proceeded steadily in all of the cultures up to the fifth day. From then on some cultures did not increase further in gum content, while others showed a decrease in the rate. After 7 and after 14 days' incubation, some cultures tested showed about the same gum content, while others showed a decrease in the second week. Considerably more gum was produced at the optimum temperature than above or below, indicating that gum production is probably a normal metabolism process. When cultures of *Rhizobium* were grown in 500-, 250-, and 125-cc

Erlenmeyer flasks each containing 100 cc of medium, the most gum in all cultures tested was produced in flasks allowing the largest surface exposure, and gum production became smaller as the surface area exposed was decreased.

Since ability to produce a viscid solution seemed to characterize certain species of *Rhizobium*, differences in viscosity-producing power might be of value in differentiating species. In viscosity tests made on 59 strains representing 8 different species, the cultures were grouped on the basis of ability to increase the viscosity of a glucose-yeast-extract medium. The first group, including strains of *R. meliloti*, *R. japonicum*, *R. lupini*, and the cowpea bacteria, produced little or no increase in the viscosity of the culture solution, while organisms of the second group, including *R. trifolii*, *R. leguminosarum*, *R. phaseoli*, and probably the *Dalea* bacteria, produced a marked increase in the viscosity of the culture solutions. The viscosities of these cultures ranged from 1.2 to 2.4 times that of the sterile medium. Differences in the chemical nature of the gums produced by the various species seemed to play an important part in determining the ability of the organisms to increase viscosity of the solution cultures.

Purified gum supplied as a carbohydrate source for growth of *Rhizobium* evidently was not utilized by the organisms under the conditions of the experiment.

Photosynthesis in various portions of the spectrum, G. R. BURNS (*Plant Physiol.*, 8 (1933), No. 2, pp. 247-262, figs. 3).—Using as a measure the change in the amount of carbon dioxide in an artificial atmosphere, data were obtained at the Vermont Experiment Station on the photosynthetic activity of white pine, Norway spruce, and Engelmann spruce seedlings held at a constant temperature of $28^{\circ} \pm 0.5^{\circ}$ C. in gas sealed jars exposed to the light of four 1,000-w Mazda lamps passed through a water filter alone and through water filters plus various color filters, including red, red-yellow, and blue-violet. Infrared radiation of wave lengths longer than 1,100 $m\mu$ proved detrimental to photosynthesis, and the author assumes that radiations of wave length longer than 720 $m\mu$ are useless in photosynthesis. With Norway spruce the relative quantum yields in the wave lengths 720-630, 720-560, and 470-390 $m\mu$ were 9.5, 10, and 5, and with pine 9.5, 11, and 5. The actual quantum yield with pine was found to lie between 5 and 12 quanta per mole of carbon dioxide.

A review of recent work on the effect of ultraviolet radiation upon seed plants, H. W. POFF and F. BROWN (*Bul. Torrey Bot. Club*, 60 (1933), No. 3, pp. 161-210).—This review, embracing 173 titles, deals with the effect of ultraviolet radiation upon seed germination and early growth of seedlings, general and specific effects upon more mature plants, and other effects upon seed plants.

Effect of various chemicals on the respiratory rate and sugar content of potato tubers, L. P. MILLER (*Amer. Jour. Bot.*, 19 (1932), No. 10, p. 840).—When whole tubers were subjected to the vapors of ethylene chlorohydrin, ethylene bromohydrin, ethyl mercaptan, hydrogen sulfide, ethyl disulfide, and acetaldehyde, large increases in the respiratory rate were observed to take place, whereas ethyl alcohol causes a decrease in respiratory activity. Such increases occurred very soon after the treatment (24-hour treatment period) began, and reached their maximum the second or third day after the treatment, after which the respiratory rate of the treated tubers gradually fell to a value approaching that of untreated samples. Although many of these treatments resulted in increases in the sucrose content of the tubers and respiratory responses have often been attributed to sugar changes, the results did not indicate that this increased respiratory activity is caused by sugar increases. This was shown by ethylene chlorohydrin treatments, in which the largest respiratory

increase occurs very definitely before the sugar increase and there is a drop in sugar content at the period of greatest respiratory activity. The sugar content subsequently rises while the respiratory rate is falling.

Effect of chemical treatments of dormant potato tubers on the conductivity of the tissue and on the leaching of electrolytes from the tissue. J. D. GUTHRIE (*Contrib. Boyce Thompson Inst.*, 5 (1933), No. 1, pp. 83-94, figs. 2).—Treatment of dormant potato tubers with ethylene chlorohydrin produced small but significant increases in the conductivity of the tissue and increased the leaching of electrolytes from the tissue when placed in water. Treatments with potassium thiocyanate produced changes somewhat smaller but similar to those produced by ethylene chlorohydrin. Changes observed with thiourea treatments were slight and usually insignificant.

The effect of ether and chloroform upon the rate of photosynthesis in detached leaves of *Acer negundo*. R. H. WALLACE (*Amer. Jour. Bot.*, 19 (1932), No. 10, pp. 847, 848).—At the Connecticut State College quantitative experiments with ether and chloroform showed that lethal doses are required to stop the process of photosynthesis in detached leaves placed in hermetically sealed containers immersed in a constant temperature bath at 25° C. (77° F.). In numerous cases the application of sublethal concentrations of ether increased the rate of photosynthesis, due apparently to an increase in stomatal opening. It was found impossible to obtain opening of the stomata with chloroform treatment.

Effects of illuminating gas on young oak trees. C. G. DEUBER (*Amer. Jour. Bot.*, 19 (1932), No. 10, p. 845).—At Yale University the roots, dormant buds, and entire potted trees of red and black oak were subjected to atmospheres of illuminating gas mixed with air. With dormant trees gas hastened the opening of buds, but in large volumes and with long exposure inhibited bud development and even killed the trees. Hypertrophy of the root lenticels was induced by gas exposure.

GENETICS

Linebreeding. J. L. LUSH (*Iowa Sta. Bul.* 301 (1933), pp. 337-368, figs. 14).—This discusses the meaning of linebreeding, the concentration of the blood of a single individual, as distinguished from inbreeding, which involves especially the reduction in the number of ancestors.

Examples of different types of pedigrees of cattle, sheep, and swine are presented, with the coefficients of inbreeding and relationship calculated according to the methods of Wright and McPhee (*E.S.R.*, 54, p. 324).

Inbreeding and homozygosis. S. WRIGHT (*Natl. Acad. Sci. Proc.*, 19 (1933), No. 4, pp. 411-420, figs. 10).—This paper presents the theoretical calculation for the decrease in heterozygosis for sex-linked genes under different systems of mating.

Inbreeding and recombination. S. WRIGHT (*Natl. Acad. Sci. Proc.*, 19 (1933), No. 4, pp. 420-433, figs. 10).—This is a theoretical study of the recombination of sex-linked genes expected in case of different kinds of matings as determined by the correlations observed.

"The general conclusions from this analysis are that different pairs of allelomorphs, even in the same chromosome, come to be combined practically at random in any freely interbreeding population of long standing, and that there is practically random combination among the genes fixed in different inbreeding subgroups of a population unless these subgroups are very small or linkage is extremely close."

On sexual incompatibility of tetraploid hybrids of *Raphanus* × *Brassica* [trans. title], G. D. KARPECHENKO and S. A. SHCHAVINSKAYA (SHCHAVINSKAYA) (In *Trudy Vsesoiuznogo S'ezda po Genetike, Selektii, Semenovodstvu i Plemennomu Zhivotnovodstvu* (Proceedings of the U.S.S.R. Congress of Genetics, Plant- and Animal-Breeding), Leningrad, 1929. Leningrad: Izd. Redaktsionnoi Kollegii S'ezda, 1930, vol. 2, pp. 267-276, figs. 4; Eng. abs., pp. 275, 276).—No crossing was observed to take place in the open field between the fertile tetraploid hybrid of *Raphanus sativus* × *Brassica oleracea* and either parent. Where flowers of the hybrid were treated with a mixture of pollen, including their own, self-pollination occurred. The incompatibility of the hybrid with either parent is attributed to its doubled chromosome complex. According to its morphological characters, fertility, and constancy the hybrid known as *Raphanobrassica* may well be considered as a new genus and a possible example of how other constant breeding forms of plants have originated.

A contribution to the synthesis of a constant hybrid of three species [trans. title], G. D. KARPECHENKO (In *Trudy Vsesoiuznogo S'ezda po Genetike, Selektii, Semenovodstvu i Plemennomu Zhivotnovodstvu* (Proceedings of the U.S.S.R. Congress of Genetics, Plant- and Animal-Breeding), Leningrad, 1929. Leningrad: Izd. Redaktsionnoi Kollegii S'ezda, 1930, vol. 2, pp. 277-294, figs. 11; Eng. abs., pp. 293, 294).—In an attempt to secure a constant breeding hybrid of three species, *Raphanobrassica* was crossed with various crucifers, including *Brassica carinata*, swede turnip, Colza rape, horseradish, and common turnip. Crosses were readily made with *B. carinata*, despite the fact that the radish and cabbage parents of *Raphanobrassica* do not cross with this species. The resulting seedlings were normal, vigorous plants intermediate between the two parents. All hybrids were true triheterogenous plants, and it is concluded that in the F₂ generation there should appear forms with 6-paired homological genomes which ought to be fertile and constant.

Hereditary radium-induced variations in the tomato, E. W. LINDSTROM (*Jour. Heredity*, 24 (1933), No. 4, pp. 128-137, figs. 5).—As a result of experiments at the Iowa State College in which seeds, growing tips, and young developing fruits of the tomato were radiated with Monel needles having an actual radium content of 12.3 mg, there was observed a large amount of general sterility, pollen abortion, and morphological abnormalities, some of which disappeared in subsequent generations. However, six heritable recessive variations were obtained, three affecting chlorophyll, two morphological characters, and one causing sterility and stunting of the entire plant. At least three of the heritable variations were wholly different from any previously known in the tomato. Since these variations behaved genetically as simple monogenic characters, they are designated as gene mutations and are conceded to be possibly due to minute deletions of the chromatin material. The chromosome counts in all six variations were normal and typical of the species.

Studies in human inheritance, VII-IX (*Ohio Jour. Sci.*, 32 (1932), Nos. 2, pp. 152-157, figs. 6; 3, pp. 232-236, figs. 5; 5, pp. 436-440).—These papers continue the series previously noted (*E.S.R.*, 69, p. 32).

VII. Hemophilia, L. H. Snyder.—The doubtful occurrence of hemophilia in women is pointed out in selected examples from a large number of human pedigrees.

VIII. Dominance in man, with especial reference to polydactylism, D. Dehus and L. H. Snyder.—Attention is called to the fact that apparent cases of dominance in man may prove to be recessive characters when the full information is available. Several pedigrees involving the inheritance of polydactylism and syndactylism in man are presented to illustrate this view.

IX. The inheritance of taste deficiency in man, L. H. SNYDER.—An analysis is given of 800 families with reference to their ability to taste phenyl thiocarbamide. There were 3,643 parents and offspring in this group, of which 70.2 percent were tasters and 29.8 were nontasters. Good agreement was obtained between the observed and calculated behavior of the children based on the probable genotype of the heterozygous parents according to their frequency of occurrence in the population and assuming that this character is controlled by a single pair of Mendelian factors.

Inbreeding and the genetic history of the Rambouillet sheep in America, W. F. DICKINSON and J. L. LUSH (*Jour. Heredity*, 24 (1933), No. 1, pp. 19-33, figs. 4).—The results of a study of the amount of inbreeding in Rambouillet sheep are reported from the Iowa Experiment Station.

Studies were made of the pedigrees of 382 lambs born in 1896 and random samples of 400 born in 1906 and 800 born in 1916 and 1926, respectively, as reported in the American Rambouillet Record. Coefficients of inbreeding and relationship were calculated, and the study was conducted according to the sampling method developed by Wright and McPhce (*E.S.R.*, 54, p. 324). The coefficients of inbreeding and inter se relationship calculated for these years were, respectively, 2.2 ± 0.4 and 5.2 ± 0.8 , 3.8 ± 0.4 and 1.5 ± 0.6 , 3.7 ± 0.3 and 2.7 ± 0.4 , and 5.5 ± 0.4 and 2.6 ± 0.4 .

The studies indicated that the relationship of individual animals to the breed showed important changes between 1896 and 1906. On account of the many importations in that period, no single individual had a very important influence on the breed, the maximum relationship of any individual to the breed being 14.4 percent in 1896, and few exceeded 6 percent.

Tracing the pedigrees back showed that foundation animals for which no pedigrees were available were born just preceding 1894, but some were born as far back as 1880.

The average interval from generation to generation was 4.2 or 4.3 years in the four periods studied.

The genetic relation between body color and eye color in rabbits [trans. title], H. NACHTSHEIM (*Biol. Zentbl.*, 53 (1933), No. 1-2, pp. 99-109).—The author describes the influence of the various color genes, including the allelomorphs of the albino series, and spotting on eye color and coat color in the rabbit.

Rexing the lilac rabbit, R. T. PARKHURST and W. K. WILSON (*Jour. Heredity*, 24 (1933), No. 1, pp. 35-39, figs. 5).—The following F_1 population with normal and rex coats, respectively, was produced from the mating of a castorrex buck ($AA BB DD rr$) with lilac does ($aa bb dd RR$): Agouti, 190 and 44; blue agouti, 62 and 16; black, 42 and 16; blue, 15 and 5; chocolate agouti, 52 and 11; lilac agouti, 31 and 7; chocolate, 21 and 3; and lilac, 7 and 2.

The relation of sulphydryl concentration to size inheritance in the rabbit, P. W. GREGORY and H. GOSS (*Amer. Nat.*, 67 (1933), No. 709, pp. 180-185).—Determination was made of the sulphydryl content of the carcasses of different sized newborn rabbits after 48 hours' fasting. The size differences in the races used seemed to be related to the amount of sulphydryl present due to differences in the rate of cell multiplication, which is regulated by the sulphydryl concentration.

The inheritance of iso-hemagglutinogens in rabbits, R. D. CAMERON and L. H. SNYDER (*Ohio Jour. Sci.*, 33 (1933), No. 1, pp. 50-54).—The presence of one iso-hemagglutinin in rabbits seems to behave as a unit factor dominant to its absence, whereas another iso-hemagglutinin seems to be due to two allelomorph factors. Data on the inheritance of these iso-hemagglutinogens in 429

rabbits showed that the best fit to the observations was obtained from the hypothesis based on the action of three allelomorphs.

A further study of blood groups of the rabbit, C. E. KEELER and W. E. CASTLE (*Natl. Acad. Sci. Proc.*, 19 (1933), No. 4, pp. 403-411).—Studies of young and immature rabbits showed that the hemagglutinins were developed as early as the fifteenth day of gestation. In a litter of 8 embryos from an H_1 female \times an H_1H_2 male there were 2 H_1 , 5 H_1H_2 , and 1 H_2 embryos, found as determined by pulping the entire embryo in citrate solution, since the blood could not be obtained. Hemagglutinogens are apparently developed in or on the red cells, and it was impossible to separate them. As in case of the red cells, agglutinogens did not pass through the placenta. However, agglutinins do pass through the placenta, as determined in the young of a $O \times O$ mating in which the doe received blood injections from an H_1H_2 rabbit. The blood of the young was devoid of H_1H_2 agglutinogens, i.e., red cells were not agglutinated, but both agglutinins were present and agglutinated red cells from H_1H_2 rabbits.

The agglutinating properties of blood were tested in 7 of the 16 possible combinations of donors to recipients, and it was found that agglutinins were produced in the recipient when blood bearing different agglutinogens was transferred from the donor. The agglutinogens are inherited, and the genes for them are completely dominant. The agglutinins are specific antibodies produced in response to the presence of agglutinogens.

It is suggested that a somewhat different situation exists in man, in that the presence of an agglutinin is due to the absence of an inherited agglutinin to absorb it.

Waved: An autosomal recessive coat form character in the mouse, F. A. E. CREW (*Jour. Genetics*, 27 (1933), No. 1, pp. 95, 96).—A mutation called "waved", involving waves in the hair of the young mouse which disappear with age, is described. In three types of matings "waved" proved to behave as a single recessive autosomal character.

Preliminary symbols for a tail-mutation in mice, N. DOBROVOLSKAIA-ZAVADSKAIA (*Amer. Nat.*, 67 (1933), No. 709, pp. 186-188).—Symbols are suggested for describing the tail mutations in mice. These include reduced numbers of coccygeal vertebrae (brachyury) and two kinds of kinky tail, as well as other variations.

Inherited and acquired factors in resistance to infection, I, II, L. T. WEBSTER (*Jour. Expt. Med.*, 57 (1933), No. 5, pp. 793-817, figs. 2; pp. 819-843, figs. 6).—Two papers in this series are briefly noted.

I. Development of resistant and susceptible lines of mice through selective breeding.—The hybrid strains of albino mice at the Rockefeller Institute showed a mortality of 37.4 ± 1.6 percent when 771 mice were treated with uniform doses of *Bacillus enteritidis* by a standardized method. By selection based on the mortality of the young, but without treatment of the parents, susceptibility to the treatment was increased to an average of 60.9 percent for 18 lines in the first generation. The susceptibility was further increased to approximately 80 percent in the fifth and sixth generations by the same method of selection.

Resistant strains were selected in a similar manner. The average mortality of these strains in different selections subjected to the test varied from 11.3 to 20.1 percent. The susceptibility and resistance, respectively, were not increased in the later generations of selection.

The F_1 progeny of a cross of a susceptible line showing 89 percent mortality with a resistant line showing 15 percent mortality were 17.7 percent susceptible, but mortality in the back-cross to the susceptible line was 61.2 percent, and in

the back-cross to the resistant line 26.3 percent. The mortality in the F₂ generation was 34.2 percent.

The results indicate that the resistance is due to multiple factors of which one or more are dominant but not sex-linked. Segregation of the factors was demonstrated in the back-cross and F₂ generations. When exposed to herd infection the lines acted consistently with the results obtained from direct inoculation.

II. *A comparison of mice inherently resistant or susceptible to Bacillus enteritidis infection with respect to fertility, weight, and susceptibility to various routes and types of infection.*—In attempting to study further the nature of the degree of resistance to *B. enteritidis* noted in various strains of mice in the above paper, the rate of mortality to intrastomachal, subcutaneous, intraperitoneal, intravenous, and nasal inoculations of *B. enteritidis*, *Pasteurella avicola*, *B. friedlaenderi*, pneumococcus, and the virus associated with louping ill were investigated.

The strains susceptible to *B. enteritidis* administered by the intrastomachal method were likewise susceptible to the organism administered in other ways and to the intranasal administration of *P. avicola*, *B. friedlaenderi*, and pneumococcus, but not so susceptible to the virus of louping ill as strains that were more resistant to *B. enteritidis*. There were no significant differences in the resistance to the organisms administered intraperitoneally.

From these results it is concluded that the resistance of the animal to these organisms is general and not due to a special mechanism in certain parts. The inherent resistance to *B. enteritidis* was associated with the relative weight of different strains, but was not related to fertility.

[Genetic factors that determine hatchability] (*Connecticut Storrs Sta. Bul.* 181 (1932), p. 7).—A brief description is given of the homozygous creeper embryos surviving the typical lethal period at the end of the third day of incubation.

Collateral and ancestral correlations for sex-linked transmission irrespective of sex, E. CHARLES (*Jour. Genetics*, 27 (1933), No. 1, pp. 97-104).—Theoretical correlations expected in case of complete and incomplete dominance for sex-linked inheritance between relatives, with equal distribution of the sexes, are presented.

Partial sex reversal in the fowl, F. D. REED and C. L. MARTIN (*Poultry Sci.*, 12 (1933), No. 2, p. 90, fig. 1).—A brief account is given of a hen which had previously been a good layer, but subsequently developed male secondary sex characters. On post-mortem examination two typical testicles of normal appearance were found.

The hypophyseal substance giving increased gonadotropic effects when combined with prolactin, H. M. EVANS, M. E. SIMPSON, and P. R. AUSTIN (*Jour. Exptl. Med.*, 57 (1933), No. 6, pp. 897-906).—A synergistic effect of mixtures of prolactin and hypophyseal preparations on ovarian development was demonstrated by the markedly greater weight of the ovaries of the test animals, to which both prolactin and the growth-promoting and gonadotropic hormones of the hypophysis were administered, than was obtained by combining the weights of the ovaries of animals to which only one of the preparations was given. The essential hypophyseal hormone was administered with either the gonadotropic or the growth-promoting factors, but the essential material was prepared sufficiently free of both of these hormones to indicate that neither was responsible.

Recent advances in the chemistry and biological assay of oestrin, G. F. MARRIAN (*Physiol. Rev.*, 13 (1933), No. 2, pp. 185-221).—A review is given of recent advances in chemistry which have resulted in the isolation of the oestrus-producing hormone from the ovarian follicle in pure crystalline form.

Rat seminal vesicles and prostate glands as quantitative indicators of testicular hormone. I. B. HANSEN (*Endocrinology*, 17 (1933), No. 2, pp. 163-179, figs. 2).—A study was made of the condition of the prostate gland and seminal vesicles of rats at intervals after castration and after subsequent injections of the testicular hormone. The method giving the most satisfactory and uniform results involved the administration of 10 daily doses of the hormone beginning on the day following castration. Attempts were made to measure the dose of the hormone quantitatively by the changes in these glands. The indices proving most satisfactory as quantitative measures in the seminal vesicles were the presence of secretion, secretory granules with halo, and cell height. Epithelial height and the presence of light areas in the prostate proved efficient measures of doses of from 0.15 to 1.5 bird units. Doses from 0.4 to 7 bird units were measured by the seminal vesicles.

Experimental studies on the hypophysis cerebri.—I, The effect of single pregnancy in the albino rat, S. I. STEIN (*Endocrinology*, 17 (1933), No. 2, pp. 187-198, figs. 6).—A comparative study of the hypophyses of control rats and rats in their first pregnancy showed no differences in the number, size, shape, nuclear pattern, staining reactions, or distribution of the cells in the gland. No definite type of cells was found in the pregnant groups that could be designated as the so-called "pregnancy cells."

FIELD CROPS

[Field crops investigations in Nebraska] (*Nebraska Sta. Rpt.* [1932], pp. 10-14, 29-31, 36, 37, 40, 41, 42, 43, 44).—Research with field crops (E.S.R., 67, p. 517) again reported on from the station and substations included variety tests with oats, barley, spring and winter wheat, corn, and alfalfa; breeding work with corn, wheat, oats, and alfalfa; studies of selection for seed purposes, degeneracy in seed stocks, and strain tests, all with potatoes; cultivation (including planting) experiments with corn, potatoes, sorgo, and sugar beets; the draft of corn and alfalfa on soil moisture; control of stinking smut in wheat; crop rotation and fertilizer experiments involving corn, wheat, and oats; rotation and tillage studies on dry land; and rotations under irrigation. Several lines of work were in cooperation with the U.S. Department of Agriculture.

[Agronomic investigations in the Virgin Islands, 1932], G. BRIGGS and C. L. HORN (*Virgin Islands Sta. Rpt. 1932*, pp. 3, 7-11, 13, figs. 2).—Field crops work (E.S.R., 67, p. 518) again reviewed briefly included variety trials with grain sorghum, sorgo, broomcorn, sugarcane, tobacco, sweetpotatoes, cowpeas, velvetbeans, pigeonpeas, alfalfa, and miscellaneous legumes; breeding work with corn and sugarcane; production and palatability tests with forage grasses; storage experiments with sweetpotatoes; and control of pink bollworm.

Chemical composition of native Alaskan hays harvested at different periods of growth. R. G. CAPEN and J. A. LEClerc (*Jour. Agr. Res. [U.S.]*, 46 (1933), No. 7, pp. 665-668).—Analysis by the U.S.D.A. Bureau of Chemistry and Soils of 51 samples of 6 forage plants, grown at the Alaska Experiment Station at Fairbanks in 1929, for moisture, ash, crude protein, fat, fiber, and sugar, showed that as the season advanced the percentage of protein decreased, especially in *Calamagrostis* sp., while the percentage of fiber increased. The ash content of sedge (*Carex* sp.) and *Calamagrostis* sp. was higher than that of cotton grass (*Eriophorum* sp.) at every growth stage. The ash content of *Calamagrostis* sp. was higher in late cuttings than in the earliest, while the

reverse was true with cotton grass and sedge. Sedge and cotton grass slightly exceeded *Calamagrostis* sp. in fat content. The native forage plants of Alaska on the whole compared favorably with vetch and bromegrass but not with yellow-flowered alfalfa.

Since the feeding values of the native hays decrease rapidly after August as shown by the decrease in protein and the increase in fiber, it would seem advisable to harvest these varieties late in August or early in September.

A comparison of the wet and the dry methods of inoculating legume seed. H. W. BATCHELOR and I. H. CURIE (*Ohio Sta. Bimo. Bul.* 162 (1933), pp. 71-74).—Field and greenhouse tests on 6 commercial soybean inoculation cultures in 1932 gave indications that the newer types of dry cultures are inferior to the older types of wet cultures in number of nodule-forming bacteria supplied per pound of seed, as well as in ability to inoculate as many plants and to produce as large yields of nodules. The dry method of applying inoculation appeared distinctly inferior to the wet method.

Recent progress in breeding borer resistant corn. A. R. MARSTON (*Mich. Sta. Quart. Bul.*, 15 (1933), No. 4, pp. 264-268, fig. 1).—Further progress (E.S.R., 67, p. 33) was made in efforts to produce strains of corn markedly resistant to European corn borer by crossing native varieties with Maize Amargo, inbreeding, and selection. Maize Amargo, it was established, has a heritable characteristic making it resistant to borer attack. From crosses between Maize Amargo and native corn, strains evidently may be selected which apparently are as resistant as pure Maize Amargo. Belief that such resistance is due to late maturity of the resistant lines was not warranted since some of the most highly resistant were as early as the very susceptible Duncan, while some susceptible lines were much later. That resistance in selected Maize Amargo × native corn inbreds is not due to lack of vigor was demonstrated by the susceptibility of the native corn × native corn inbreds equally lacking in vigor, and by the continued resistance of selected blends of Maize Amargo × native corn inbreds, such blends having regained full vigor and productivity.

Rate of planting corn for grain. J. R. DUNCAN (*Mich. Sta. Quart. Bul.*, 15 (1933), No. 4, pp. 292, 293).—Early, medium, and late varieties of corn were planted in 3.5 by 3.5 ft. hills at rates of 2 to 6 kernels per hill, during the period 1928-31. The results indicated that large-growing varieties, requiring the full season to mature, will give the most and best grain at 3 kernels, while earlier and shorter sorts will do best at 3 to 4 kernels per hill, and will decrease in yield and quality with heavier planting rates. The percentage of marketable ears of the late corn was greatest in thin plantings, gradually decreasing as the planting was thicker. In medium and early strains there was no decrease in marketable ears until more than 4 kernels per hill were planted.

Cultivation of corn. H. L. BORST and G. M. MCCLURE (*Ohio Sta. Bimo. Bul.* 162 (1933), pp. 75-77).—Corn grown during the period 1926-32 on two soil types at Columbus was hoed only to remove weeds, cultivated (usually three times) to control weeds, and given more cultivation (usually four times) when needed to control weeds. On the dark Brookston silty clay loam, no cultivation treatment resulted in higher shelled corn yields than were made when the weeds were hoed only. On the light Miami silty clay loam cultivated plats averaged 3 bu. more corn per acre than on hoed plats, and one or more cultivations in addition to those needed for weed control resulted in a further increase of nearly 3 bu. Fodder yields showed similar gains. There was evidence of higher soil moisture contents on the cultivated plats, especially on the Miami soil.

Breeding varieties of cotton to meet the needs of mechanical harvesting. D. T. KILLOUGH (*Valley Farmer*, 5 (1932), No. 9, p. 1; *abs. in Texas Sta. Circ.* 68 (1932), p. 26).—A popular account of the progress of efforts to develop a strain of cotton adapted to mechanical harvesting.

Effects of varying amounts of potash on oil and protein and on the weight and percentage of cotton seed. J. F. O'KELLY, W. W. HULL, and M. GEIGER (*Mississippi Sta. Tech. Bul.* 20 (1933), pp. 8, figs. 3).—Seed cotton grown in fertilizer tests at the station and at the Raymond and Poplarville Substations, and in simple side-dressing trials involving potash salts, was examined for oil and protein content, seed size, and lint percentage.

Application of fertilizer containing nitrogen and phosphorus alone resulted in a decrease in oil content as compared to the oil content of seed produced without fertilizer. Addition of potash to the fertilizer increased the oil content and usually each successive potash increment produced a corresponding increase in the oil per ton of seed, especially where such increments increased yields of seed cotton. On the other hand, nitrogen and phosphorus without potash increased the protein content above that produced without fertilizer. Potash increments added to the mixture decreased the protein content, but not always in direct proportion to the amount applied. Yields of seed cotton were increased more than enough to offset this depressing effect of potash on the protein content, and more protein per acre was produced where potash was used than where it was omitted. In general, potash tended to increase the weight of the seed and to decrease the seed percentage, but probably not to a significant extent.

Comparative advantages of jute and cotton baggings for American cotton bales. J. W. WRIGHT and R. J. CHEATHAM (*U.S. Dept. Agr., Bur. Agr. Econ.*, 1933, pp. [2]+24, pl. 1, figs. 3).—The status of jute and cotton as bale covering materials is reviewed, and the merits of the two materials are compared. Jute can withstand the rough handling which cotton bales receive, but it lacks durability, has excessive weight, and the presence of jute fibers in cotton causes spinning losses. Cotton bagging is durable, light, and contributes to neatness of the package. It is thought that the lower cost of jute bagging may be offset by the greater re-use value of cotton bagging, savings in freight and insurance and in cotton adhering to bagging, and increased consumption of cotton.

Variable practice in milo production. H. H. FINNELL ([*Oklahoma*] *Panhandle Sta., Panhandle Bul.* 49 (1933), pp. 8).—Examination of grain yield data obtained from systematic and variable practices in milo production over the period 1924-32 showed that with an inflexible system, best results have been obtained by regularly fall listing and planting a full stand, although it might be highly profitable to use soil moisture indications to determine a successful variable practice. The first possibility is in the fall when useless or possibly detrimental tillage may be eliminated if moisture favoring proper listing is lacking. Taking account of any moisture deficiency within 3 ft. of the surface at planting time permits a corresponding reduction in the stand that favors a more efficient use of available moisture.

Growing combine grain sorghums. L. C. AICHER (*Kansas Sta. Circ.* 170 (1933), pp. 19, figs. 14).—Cultural and harvesting practices suitable for growing grain sorghums to be harvested with the combine are outlined, largely from experiments at the Fort Hays Substation. The characteristics of varieties for the purpose are described.

Wheatland, the best variety available, a straight-necked kafir-milo hybrid bred by J. B. Sieglinger of the U.S. Department of Agriculture at Woodward,

Okla., has a growing season slightly over 100 days, is 32 in. high, does not lodge, yields well, and threshes easily, but is susceptible to chinch bug injury.

Combine sorghums yield well on properly prepared good soil, especially on fallow or well-prepared barley-, wheat-, or corn-land. Blank listing in the fall, throwing in when weeds first appear in the spring, and additional tillage for weeds with the one-way or spring-tooth harrow once or twice before planting constitute the best method of preparing land.

Good results were had by planting with lister or loose-ground lister-planter at 3 to 5 lb. per acre in 42 in. rows, or 5 to 7 lb. with the deep-furrow drill or common drill in 14 in. rows, and during the first week in June. Cultivation is largely accomplished by completely destroying weeds while preparing the seed bed. Combine sorghums should not be harvested until the grain is dry enough to keep in a grain bin, i.e., containing not more than 13.5 percent moisture.

Effects of inoculation and liming on soybeans grown on the Grundy silt loam. R. H. WALKER and P. E. BROWN (*Iowa Sta. Bul. 298 (1933), pp. 277-296, figs. 11*).—Experiments to determine the effects of liming and inoculation on the yield and quality of soybeans grown on typical Grundy silt loam were made near Osceola in Clarke County. Different plats received from 1 to 6 tons per acre of quarry-run limestone; 20-, 40-, and 100-mesh sieved limestone (3 tons); and hydrated lime equivalent to 3 tons of quarry-run limestone.

Soybean (Manchu) plants on the inoculated half of each plat were well-supplied with nodules of nitrogen-fixing bacteria, and grew much more vigorously and appeared healthier than the uninoculated plants, which showed practically no nodules. Inoculation increased the number of pods per plant twofold and fourfold in certain cases. The hay yield was nearly doubled and the seed yield tripled because of the combination of liming and inoculation, and the protein percentage in the hay was practically doubled and in the seed increased about one third. Inoculation alone always had a greater effect than lime treatments alone, although best results came when the two treatments were combined. For best results with soybeans on this soil, the seed should be inoculated and the soil limed.

The liming studies indicated that limestone of good quality should be applied to acid soils, Grundy silt loam, or similar soils on which soybeans are to be grown. Preferably it should be 90 percent or higher in carbonate content, ground to at least 60 percent dust, and, if possible, applied at least a year before the legume is planted, although some benefit may be derived from limestone applied just before planting. It should be applied in amounts indicated as necessary by the lime requirement test.

Proceedings of the Fourth Congress of the International Society of Sugar Cane Technologists, held at San Juan, Puerto Rico, March 1st-16th, 1932, edited by J. BAGUÉ (*San Juan: House Represent. Puerto Rico, 1932, pp. XV+174+[969], pls. 17, figs. 330*).—The sessions of this Congress comprised general and sectional meetings dealing with diseases, cultural and field practices, varieties, factory operation and chemical control, and insect pests.

Papers of special interest to agronomists included *The Varietal Revolution in Puerto Rico*, by C. E. Chardon (pp. 23-31); *Sugar-Cane Growing in Puerto Rico*, by F. A. López Domínguez (pp. 35-42); *Soil Classification*, by C. F. Marbut (pp. 43-48); *Cultivation of Ratoons in Hawaii*, by W. W. G. Moir (Bul. 9, pp. 8); *Cultivation Experiments with Sugar Cane—I, The Effect of Type of Preparatory Tillage on Yield of Plant Canes*, by P. E. Turner (Bul. 15, pp. 7); *Report on Agricultural Practice in the South African Sugar Industry*, by H. H. Dodds

(Bul. 120, pp. 8) ; Notes on the Sugar Industry of Puerto Rico—I, Practices Common to the Northern, Eastern, and Central Region, by R. C. McConnie and L. de Celis (Bul. 86, pp. 1-36), and II, The Cultivation of Sugar Cane in the South Side of the Island of Puerto Rico, by M. Obén (Bul. 86, pp. 37-62) ; Brief Historical Review of Sugar-Cane Fertilization in Porto Rico, by I. A. Colón (Bul. 83, pp. 7) ; Molasses as a Fertilizer, by H. W. Kerr (Bul. 56, pp. 2) ; A Preliminary Study on the Optimum Reaction of the Nutrient Medium for Sugar Cane (Bul. 12, pp. 6) and Ammonium Versus Nitrate as Nitrogen Sources for the Sugar Cane (Bul. 13, pp. 16), both by J. Bremer (Bul. 20, pp. 3); Field Trial of Co. 290, P.O.J. 2714, and P.O.J. 2725 with Uba (Bul. 118, pp. 2) and A Field Trial of Certain Colmbatore Canes in Comparison with Uba (Bul. 119, pp. 2), both by H. H. Dodds; Experiences with Cane Varieties in the Island of Cuba, by R. Menéndez Ramos (Bul. 68, pp. 23+4); Sugar-Cane Breeding in Different Countries (Being Replies to Questionnaire from Java, Mauritius, Porto Rico, Peru, Philippines, Australia, Florida, and India, Analysed and Arranged), by T. S. Venkatraman (Bul. 44, pp. 34); Some Notes on Selection of Cane Seedlings in the Early Stages of the First Year, by T. Bregger (Bul. 40, pp. 3); Sugar-Cane Crosses with Kassoer Sells, by R. L. Davis (Bul. 18, pp. 8); Sugarcane-Seedling Mosaic Elimination, by R. L. Davis (Bul. 19, pp. 17); Methods of Preserving and Describing Sugarcane Material in Taxonomic Studies, by H. B. Cowgill (Bul. 45, pp. 6); and Brief Note on Sugar Cane-Sorghum Hybrids, by T. S. Venkatraman and R. Thomas (Bul. 67, pp. 8).

The interests of the chemist and factory technologist were considered in papers entitled The Development of Sugar House Machinery and Methods of Manufacture in Puerto Rico during the Last Quarter Century, by M. A. del Valle (pp. 31-35); The Process Used in the Manufacture of Snow White Sugar at Central Mercedita, by J. R. Junghans (pp. 49-53); The Control of the Sugar Mill, by H. Schreiber (Bul. 105, pp. 2); Boilers, Furnaces, Steam, and Fuel Economy, by E. C. von Pritzelwitz van der Horst (Bul. 80, pp. 4); Electric Mill Drive, by J. J. W. Den Haan (Bul. 79, pp. 12); Recent Progress in Evaporation, as Exemplified in the Performance of the Clewiston Sugar Factory, by A. L. Webre (Bul. 54, pp. 10); Filtration of Cane Sugar Juices, by W. A. Powe (Bul. 103, pp. 9); Sulfitation Processes Employed in Sugar Factories in Egypt, by P. Neuville (Bul. 65, pp. 3); A Suggested Practical Method for Measuring Molasses Exhaustion, by J. G. Davies (Bul. 121, pp. 13); The Fermentation of Final Molasses, by H. E. Cruz Monclova (Bul. 70, pp. 7); and Clarification and Separation of Muds, by E. D. Westly (Bul. 61, pp. 5). A symposium on crystallization comprised the following papers: The Scientific Control of Pan Boiling, by S. J. Saint (Bul. 81, pp. 3); Controlling Methods in the Crystallization Process, by P. Honig (Bul. 90, pp. 6); Contributions to the Study of Crystallization of Saccharose, by K. Sandera (Bul. 62, pp. 5); The Crystallography of Sucrose, by F. P. Phelps (Bul. 104, pp. 27); X-Rays and Sugar, by G. L. Clark (Bul. 97, pp. 5); Relationship between Pan Boiling Operations and Quality of Raw Cane Sugar, by J. C. Keane and E. K. Ventre (Bul. 23, pp. 7); The Influence of Conditions during Boiling on the Composition of the Sugar Crystal as Reflected by Filtration Rate, by H. F. Bomonti (Bul. 51, pp. 6); Determination of the Saturation Temperature of Sucrose Solutions and Its Use in Finding Coefficients of Saturation and of Supersaturation, by R. W. Harman (Bul. 98, pp. 8); A Comparative Study of the Boiling Methods in the Sugar Mills of Peru, by R. Neumann (Bul. 69, pp. 6); Rapid Crystallization of Masseccutes with Special Reference to the Werkspoor Crystallizer, by R. G. W. Farnell (Bul. 120, pp. 17); and another on factory control included The Comparison of Cane Milling Results (Bul. 1, pp. 2) and On "Available

Sugar" and the Expression of the Boiling House Result (Bul. 2, pp. 2), both by N. Deerr; and Report of the Special Committee on Uniformity in Reporting Factory Data, by F. W. Zerban (Bul. 125, pp. 26).

Tobacco Substation at Windsor, report for 1932, T. R. SWANBACK, O. E. STREET, and P. J. ANDERSON (*Connecticut State Sta. Bul. 350 (1933), pp. 461-507, pl. 1, figs. 9*).—Reports are made on several experiments with cigar leaf tobacco (E.S.R., 67, p. 383), including notes on tobacco insects in 1932 by D. S. Lacroix (see page 550).

How much magnesia should be applied to tobacco land? (pp. 466-473).—Magnesium lime (30 percent MgO) was applied to adjacent plats of tobacco at rates of 100, 200, 400, and 600 lb. per acre, and the results of burn tests were correlated with magnesia content of the leaf. Magnesia increased the yield and grading, but differences between the several rates were not significant. The optimum content of magnesia seemed to be about 1.5 to 2 percent of the moisture-free weight of the cured leaf. When the percentage is lower, combustion is not so complete, and a dark ash and a less desirable taste and aroma result. With 2.5 percent or more the ash is whiter, but flakes too much. The 100-lb. rate came nearest to keeping the magnesia content of the leaf at the desired percentage during the first season. The best practice would seem to be to apply each year not more than 100 lb.

The relation of calcium to the growth of tobacco (pp. 473-478).—Greenhouse tests with Havana seed tobacco did not show deficiency symptoms when the percentage of CaO exceeded 2. There were indications that about 5 percent CaO in the air-dry leaf corresponds to optimum growth. Experiments with gypsum and with pure calcium carbonate indicated that the CaO content of the leaf increases somewhat in proportion to the lime material added to the soil. In pot tests on a rather acid soil (4.38 pH), receiving pure calcium carbonate at rates of 1 and 2 tons per acre, and ordinary tobacco fertilizer, three crops were grown. Enough lime was added to bring the reaction up to the same level for the second as for the first crop, while the third received no more lime. Wherever the calcium percentage rose the magnesium and potassium were correspondingly lowered; where the calcium content was considerably lower as in the third crop, the percentage of potassium rose to a higher level. Other experiments indicated that sodium and ammonium, to a certain extent, have a depressing effect on the absorption of calcium.

In comparisons in both sand and water cultures, different calcium compounds varied considerably in availability. Calcium nitrate produced the highest percentage of CaO in the leaf, 5.07, nitrate and sulfate (gypsum) in combination 4.96, sulfate 3.55, oxide 3.53, acetate 3.3, carbonate 3.19, oxalate 2.68, monophosphate 2.46, tartrate 2.19, no calcium salt 2, triphosphate 1.92, and calcium citrate 0.56 percent.

That calcium as a nutrient is responsible for increase in growth was shown in field and in greenhouse experiments. Other research indicated that its activity is governed by the amount of magnesia present, and vice versa. Recent studies suggested the possibility that insufficient absorption of calcium by the plant may be the ultimate cause of brown root rot. The need for calcium, as well as for other nutrients, should be considered in fertilizing Connecticut tobacco soils.

Further experiments with Nitrophoska (pp. 478, 479).—In comparative tests during 3 years, Nitrophoska appeared to consistently produce tobacco of lower grading than did the standard fertilizer formula. A tendency toward lower yields through the use of this material was also noted.

Broadleaf fertilizer experiments, J. S. Owens (pp. 479-481).—In cooperative tests on Merrimac soil, variations in nitrogen sources or rates of applying

phosphorus made only small differences in yield or quality of Broadleaf tobacco, all treatments making good crops.
